The hairpin conformational hypothesis[1] has been proposed to rationalise much of the structure–activity and receptor-binding data which have accumulated for the prostaglandin (PG) hormones. The hairpin conformation, thought to be necessary for PG activity, requires that the α- and ω-chains of the molecule be extended and in parallel alignment, separated by a van der Waals contact distance for the full length of the chains, with the ends of the chains approximately 5.5 Å apart. The similarity between the structures of the thromboxanes (TXs) and the PGs suggests that the profile of activity of TXs, like that of PGs, centres on subtle conformational variation of the hairpin geometry. Thromboxane B_2 (TXB_2) is a stable hydrolysis product[2] of a highly reactive, short-lived intermediate[3], thromboxane A_2 (TXA_2), which is formed from the prostaglandin endoperoxide (PGH_2) as indicated in Fig. 1. An examination of molecular models of TXA_2 and TXB_2 suggests that the structural differences between the ring moieties may have much less influence in altering the side-chain conformations of TXs than do substituents on the relatively more flexible cyclopentane ring of a PG molecule. We report here the first diffraction analysis of a thromboxane structure and note that the molecular conformation is not hairpin shaped.

Thromboxane B_2 was crystallised from ethyl acetate as colourless, transparent, monoclinic laths following suggestions offered by Hanessian[4]. The space group is $P2_1$, with unit cell data $a = 9.971(3)$, $b = 40.45(2)$, $c = 5.510(2)$ Å, $\beta = 102.5(1)°$, $Z = 4$, D_{obs} (flotation) $= 1.141 \text{ g cm}^{-3}$, $D_{calc} = 1.138 \text{ g cm}^{-3}$. There are two crystallographically independent TXB_2 molecules in the unit cell. The diffraction intensities were recorded from a prismatic specimen ($0.12 \times 0.12 \times 0.40 \text{ mm}^3$) in the θ–2θ scan mode on an automated diffractometer fitted with a CuKα source. A total of 2,272 independent reflections were measured out to a 2θ angle of 100°. Of these, only 1,227 intensities were considered observable ($I \geq 2\sigma I$). The crystal structure was determined by direct methods and refined isotropically by full matrix least-squares procedures to the current residual $R = 0.145$. The general weakness of the diffraction data is consistent with the high thermal motion observed for the terminal carbon atoms of the ω-chains and the disorder in $O_{(11)}$ (α and β epimers) for one of the molecules in the structure.

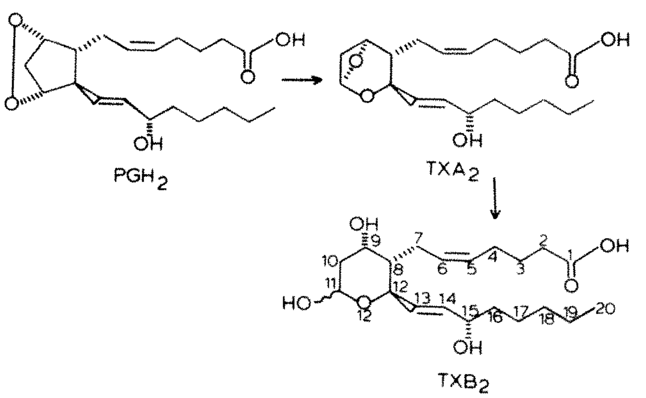

Fig. 1 Chemical formulae and numbering scheme for TXB_2 and its immediate precursors.

The two crystallographically independent molecules and their overlapped composite are shown in Fig. 2. The composite illustration was derived by overlapping corresponding atoms of both molecules in the least-squares sense[5] for the common contiguous 12-atom moiety from $C_{(6)}$ to $C_{(15)}$, excluding $O_{(11)}$. Note the torsional dissimilarities at the $C_{(4)}$–$C_{(5)}$ and $C_{(6)}$–$C_{(7)}$ bonds (Table 1). The carboxyl side chains bend sharply towards either the α or β face of the molecule. For convenience, we refer to these as the α-tail and the β-tail 'scorpion' conformers, respectively. The TXB_2 ω-chain conformations are similar but distinct. The $C_{(16)}$–$C_{(17)}$ bonds are both +synclinal rather than transplanar, as noted for every one of 12 PG ω-chain conformations studied by diffraction methods. The kinking of the chain at the $C_{(16)}$–$C_{(17)}$ bond has the effect of foreshortening the ω-chain such that it extends only as far as $C_{(4)}$ for its terminal contact with the α-chain. It can be seen from the molecular overlap figure that the $C_{(13)}$–$C_{(14)}$–$C_{(15)}$–$C_{(16)}$ torsion angles, which define the orientations of the tails of the ω-chains and which differ by 16 °, cause these tails to be slightly shifted either up or down to achieve this terminal contact with $C_{(4)}$. The end of the carboxyl chain is not stabilised by van der Waals association with the ω-chain as is the case in the hairpin conformation, and may be conformationally flexible with regard to the $C_{(4)}$–$C_{(5)}$ hinge point. Although molecular models might suggest that viable hairpin conformers of TXs may be formed close to the mean plane of the pyranose ring, we consider that such hairpin models generally crowd the side chains more closely together than if they had emanated from a cyclopentane head group. A +anticlinal $C_{(6)}$–$C_{(7)}$ bond conformation has previously been observed for each of four conformers of $PGF_{2\alpha}$ (refs 6, 7). The

Torsion angles are given to the nearest whole degree. Estimated standard errors in these values range from 2.5 to 7.0° at the C_{20} chain ends. The β-tail values are given first, followed by the α-tail values in parentheses.

0028–0836/79/380237—02$01.00

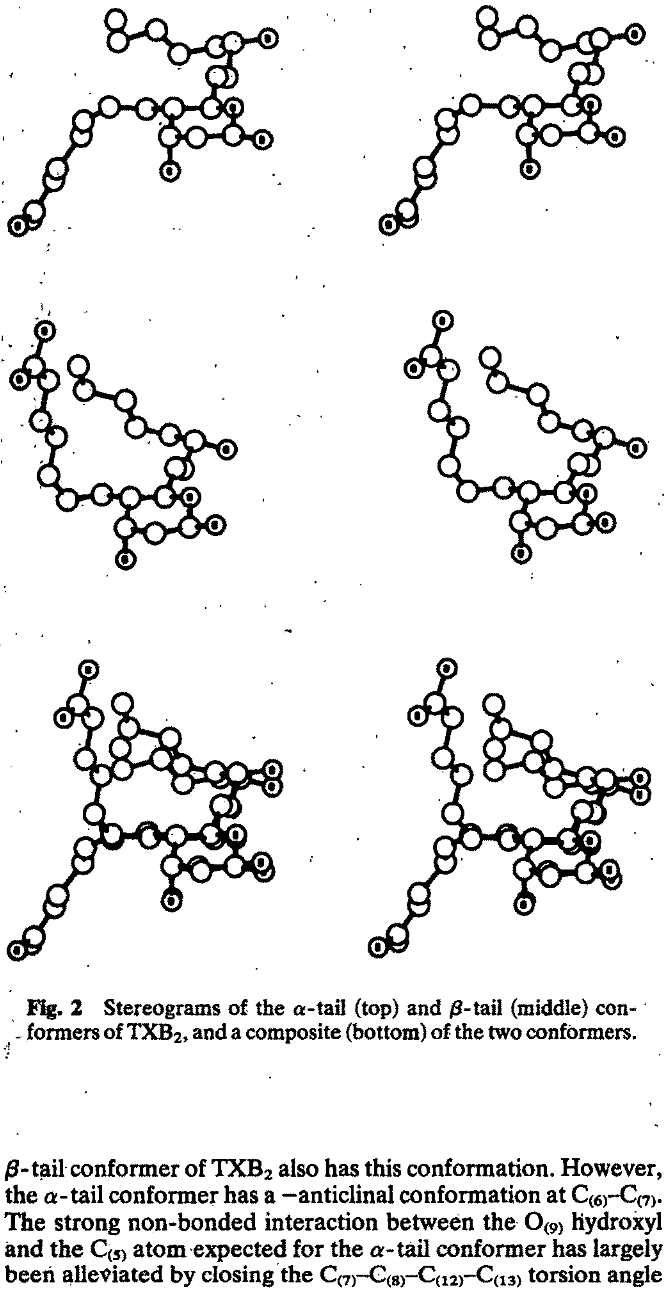

Fig. 2 Stereograms of the α-tail (top) and β-tail (middle) conformers of TXB_2, and a composite (bottom) of the two conformers.

β-tail conformer of TXB_2 also has this conformation. However, the α-tail conformer has a −anticlinal conformation at $C_{(6)}$–$C_{(7)}$. The strong non-bonded interaction between the $O_{(9)}$ hydroxyl and the $C_{(5)}$ atom expected for the α-tail conformer has largely been alleviated by closing the $C_{(7)}$–$C_{(8)}$–$C_{(12)}$–$C_{(13)}$ torsion angle from the average value of $+86 \pm 5°$ noted for the $PGF_{2\alpha}$ structures to the observed average of $+58 \pm 4°$ determined for the pyranose side-chain ring junctions of TXB_2.

Whereas the β-tail conformer is identified solely as the 11-β epimer, the α-tail conformer seems to be approximately 65% 11-β epimer and 35% 11-α epimer. Although this corresponds roughly to the 2:1 ratio noted for the unspecified methoxy-TXB_2 epimers resulting from the TXA_2 trapping experiments[3], these latter values relate to a different transition state equilibrium from that associated with anomeric equilibrium processes. The two conformers associate as carboxylic acid dimers in the crystal structure.

TXB_2 is a moderately bronchoactive metabolite[8] which survives degradation by 15-hydroxy-prostaglandin dehydrogenase (PGDH) in the lung[9,10]. The $C_{(15)}$ hydrogen positions of both conformers may be obstructed from the β-facial approach[11,12] of the nicotinamide group of NAD^+ by the +gauche twist in the ω-chain at $C_{(16)}$–$C_{(17)}$; in addition, the $C_{(15)}$ hydrogen may be obstructed by the α-chain in the β-tail conformer. This may constitute a desirable but not necessarily essential condition for TXB_2 resistance to PGDH metabolism, as the scorpion conformations may be sufficiently different to prevent binding. Although significant amounts of TXB_2 are degraded by PGDH in an antigen-challenged isolated perfusion preparation of sensitised guinea pig lung tissue[13], this is not at variance with its resistance in normal physiological conditions. This observation does suggest, however, that thermodynamic preference for the scorpion conformers is not sufficient to prevent less probable but conformationally more compatible forms of the substrate from reacting with the enzyme over prolonged exposure periods.

TXA_2 is physiologically active as a constrictor of coronary arteries[14] and as a potent platelet aggregator[3] in thrombus formation, whereas TXA_1, derived from PGH_1, lacks both activities. This has implied the chemical importance of *cis*-Δ^5 unsaturation for hormonal recognition in platelets and vascular smooth muscle[15,16]. The present study calls attention to the conformational importance of the *cis*-Δ^5 bond to produce α-tail and β-tail scorpion conformers. It remains to be shown whether the structure of TX receptors fits either of these conformational models and whether the conformational requirements for platelet and smooth muscle receptors are different.

The TXB_2 samples used in this study were synthesised[17–19] at the Upjohn Company, and provided by Drs Bundy and Pike. This work was supported by grant no. HL-15378 awarded by the National Heart, Lung and Blood Institute, DHEW.

THE MACMILLAN DICTIONARY OF ASTRONOMY

Valerie Illingworth

This Macmillan Dictionary reflects the explosive growth of astronomy in the last few years. It contains up-to-date references to the many exciting developments and discoveries that have been made in these years as well as to established theories.
It is a concise and comprehensive work; fully cross-referenced, it contains illustrations and diagrams making it the ideal personal reference book for both the specialist and the interested layman.

Tour of statistical history

Stephen M. Stigler

The History of Statistics in the Seventeenth and Eighteenth Centuries, against the changing background of intellectual, scientific and religious thought. Lectures by Karl Pearson given at University College, London, during the academic sessions 1921-1933. Edited by E. S. Pearson. Pp. 744. (Charles Griffin: High Wycombe, UK, 1979.) Paperback £7.50.

Pearson with the Brunsviga adding machine, 1910

Courtesy University College, London, UK

KARL PEARSON combined apparently boundless energy with a wide-ranging enquiring intelligence and indomitable perseverance to produce a remarkable career as a philosopher, physicist, mathematician, statistician, historian, editor, biologist and teacher. Pearson will doubtless be best remembered as a statistician. His first statistical publication was a letter to *Nature* on asymetrical frequency curves (published October 26, 1893). Over the succeeding decade he produced such widely known techniques as the χ^2 test, and he was primarily responsible for the early development of correlational analysis. The fact that such a basic term as "standard deviation" was first introduced by Pearson is testimony to the ubiquity of his influence upon subsequent statistical thought. When Pearson died in 1936, at the age of 79, he left behind a published legacy so extensive that a medium-sized hardcover book was required for his bibliography alone. He also left behind a large archive of correspondence and unpublished lecture notes, and it is from this latter source that this present volume has been drawn.

Before Pearson's emergence as a researcher in statistical methods in 1893, he had demonstrated an interest and ability in the history of science through his editing and completion of the second volume of Isaac Todhunter's *A History of the Theory of Elasticity and of the Strength of Materials from Galilei to the Present Time* (1893). After the War his thoughts returned to historical matters, as he sought to complete a massive biography of Francis Galton, and from 1921 to 1933 he gave a course of lectures at University College, London, on the history of statistics. Fortunately for all of us the notes of these lectures have survived and found the perfect editor — Pearson's son Egon S. Pearson, himself justly celebrated for both his innovative research in statistics and his insightful accounts of its history.

Karl Pearson was known as a spell-binding lecturer, and a good sense of his pace, method and vocal energy comes across on these pages. Apparently Pearson's habit was to draft his lectures *in extenso,* as if for reading, and it is these drafts which have survived. Thus, the present work is essentially a verbatim recording of the lectures of a master lecturer, a connected and detailed account of its topic at a pace (and with the necessary digressions) to hold a listener's attention. For the most part this is not the dry chronological account that so many histories of this field become, but it is Karl Pearson speaking to us. Sometimes he is earnest and scolding, as when he remonstrates with d'Alembert for a failure to test his philosophical views experimentally (page 542); sometimes he goes off on interesting, if irrelevant digressions, as when he disputes statements that Lagrange's first marriage had been incompatible (page 578). Occasionally there are flashes of humour, as when, after explaining how Lagrange loved to abandon himself to mathematical thought while listening to music, Pearson wrote: "Luckily 'Jazz' was not then invented, or the result might have made him a circle-squarer, rather than one of the greatest of mathematicians" (page 576).

These lectures cover the period from John Graunt's 1662 *Observations on the London Bills of Mortality* to Laplace's 1812 *Théorie Analytique des Probabilités,* with considerable emphasis on biographical detail and personality. The coverage reflects Pearson's interests and his taste for philosophy. There is extensive discussion of early work by the political arithmeticians (including estimation of population, construction of life tables, and inference about the sex ratio), but very little on the handling of astronomical or geodetical data. Pearson took a particular fancy to individuals with an interest in both mathematics and theology, and Richard Price receives the benefit of 52 pages of discussion. In his discussion of the later mathematicians, Lagrange and Laplace, Pearson's attention is more focussed on mathematical detail, in the manner of Todhunter's *A History of the Mathematical Theory of Probability.* But even here he exults when he encounters an antecedent to one of his own results. His discovery (page 599 *et seq.)* that Lagrange had almost derived the χ^2 distribution in about 1770 shows us both the excellence of Lagrange's mathematical skills and Pearson's own tendency to elevate mathematical form above statistical concept.

As a history of statistics, the book is not without its defects, and many are pointed out by the editor in his preface. There are errors of fact (though few misprints) that Pearson would likely have caught had he revised the lectures himself, and at times the length of the exposition makes for heavy going. The views presented of past accomplishments are dated by being rooted in Pearson's own work, and the background of religious thought and political movement that

Pearson gives in many extensive digressions is not, I think, successfully integrated into the discussion of the development of statistical methods. Bibliographical details are generally given accurately, but references to even those secondary sources available to Pearson are scarce. But these are all minor problems compared with the rare opportunity we have been given to sit at the feet of this energetic and learned professor as he takes us on a personalised tour of statistical history, and we often learn as much in the process about Pearson as we do of his subject. Here Pearson speaks of a table of Simpson's as "probably faked" (page 387); there Pearson laments that the brains of Lagrange and Laplace were not preserved for later study (page 585); and there Pearson faults Euler for failure to compile numerical tables "which would energise the symbols" (page 245). Whether we are annoyed by his opinionated view of history or enthralled by his enthusiasm, we cannot fail to be fascinated and grateful for this chance to witness these lectures.

The editor, E. S. Pearson, has done an excellent job of piecing together the different versions of several lectures, furnishing a useful index and many notes, and cutting wisely where cutting was needed. The publishers must be congratulated for keeping the price at what must, for a volume of this size, be considered low. We may hope that this encourages many scientists (not only statisticians) to make the acquaintance of the extraordinary Karl Pearson. □

Stephen M. Stigler is a Professor in the Department of Statistics at the University of Chicago, Illinois.

Nutrition planning

Nutrition and National Policy. Edited by Beverley Winikoff. Pp. 580. (MIT Press: Cambridge, Massachusetts, and London, UK, 1979.) £15.75.

THIS book is a monument to nutrition planning, the latest enthusiasm to sweep the nutrition profession as it looks desperately for some effective action with which to improve the health problems of developing countries.

Nutrition planning is a controversial approach the more coherent advocates of which argue that protein energy malnutrition in children must not be seen simply as a disease entity demanding clinical treatment. It is a disease of the poorest of the poor, a symptom of deprivation, the product of a lack of wealth and welfare which can only be eliminated by action at the economic level. As the object of development planning is to help reduce these same inequalities, three important consequences follow. Nutritional status will be improved by successful development strategies, and the improvement in nutritional status must be one of the objectives of a good development policy. Conversely, the extent of malnutrition serves as an indicator of the effectiveness of those programmes.

This approach is one that I and many of my colleagues find acceptable. Many others do not agree, finding it unrealistic or unnecessary. These are legitimate differences in opinion, a source of mutual respect and a fruitful academic dialogue.

Unfortunately, although nutrition planning is an exciting theory, it is also a popular idea. The concept of nutrition planning has not been accepted but the image has, and this has become the portmanteau justification of tarted up versions of the same tired old theories that failed in the past. Sadly, ideas change slowly: they are simply renamed and thereby extended.

From all this comes, I assume, this book — almost 600 pages of mostly unnecessary prose with all too few passages that are worth reading. Two-thirds of the book are devoted to 'case studies' of national nutrition policies largely by the representatives of various developing countries. Apart from a brilliant study of malnutrition in Chile by G. Solimano and P. Hakim, which is a précis of their book (*Development, Reform, and Malnutrition in Chile*, MIT Press; for review, see *Nature*, **276**, 542; 1978) on this topic, these national presentations are mediocre indeed. If nutrition students presented, as their view on nutrition planning, the hotch potch of miscellaneous data that seem to satisfy some of these planners they would fail their degrees. Why then are they included here? One possible reason lies in the origins of the book, which is the edited proceedings of a conference funded by the Rockefeller Foundation which took place at a Rockefeller mansion in Bellagio, Italy in 1975.

There is a growing tendency in international jamborees devoted to such areas of nutrition to invite participants not by eminence, or relevance, but by race. This may be politically expedient, but it is bad for science, and ultimately insulting to those who only get invited as statutory representatives of the third world. I do not know how far this consideration governed the structuring of this meeting, but, distasteful though the idea is, it would explain the quality of the papers selected, which add little to human understanding and detract from the science of nutrition.

It seems to me that nutritionists in government should at least have details of the prevalence of malnutrition in their countries, and changes in that rate with development policy. No such luck. If these authors are really reporting the understanding of nutrition planners in their countries, then either systematic data is not being collected, or no-one exploits it in the way that is surely a precursor to its use in the political decision making process.

We do not need them to report over and over again that malnutrition occurs in children, or even that the poor are nutritionally worse off than the rich. Such information is not in doubt. It is clear that the poor suffer. What is also clear is that even at the worst not all the poor are malnourished. Nutrition planning will only proceed effectively when the political decision makers are given some idea of which socially or ecologically defineable groups are at greatest risk, so that social policy can then be designed to help those groups.

In this book economic and nutritional information is presented in abundance, but it is presented neither within a framework that presupposes such action nor in the form that can be used by the reader to develop his own theories. I cannot imagine a politician being interested in such ramblings. These are not case studies they are travelogues compounded of largely uncollated nutritional and economic data, and peppered with politically tactful remarks.

When the book gets on to generalisations it improves somewhat, but still says little at great length. Towards the end it is suggested that Hong Kong, Singapore, South Korea and Japan have radidly improved nutritional status as a result of income redistribution. I am not convinced, but given that it is even tenable why doesn't the Rockefeller Foundation now fund a less lavish session to discuss the situation in these countries. If it were done coherently, those of us interested in this proposition could see whether given the political will, economics alone was the answer to nutritional problems. That at least would provide a test of the nutrition planning hypothesis in a way that the present volume notably fails to do.

John Rivers

John Rivers is Lecturer in the Department of Human Nutrition at the London School of Hygeine and Tropical Medicine, London, UK.

- In the review of *Atomic Absorption Spectroscopy* (see *Nature*, **280**, 705; 1979), the author's name was incorrectly quoted. This should have read M. Slavin.
- *Origins: What New Discoveries Reveal about the Emergence of Our Species and Its Possible Future* (for review, see *Nature*, **270**, 108; 1977), by Richard Leakey and Roger Lewin, has been published in paperback by Macdonald and Jane's (London, UK).

BIOTECHNOLOGY LETTERS

A monthly journal for the rapid communication within two months of acceptance of results in the applied aspects of microbiology and biochemistry in combination with chemistry and process engineering. BIOTECHNOLOGY LETTERS publishes short original communications of new work and reports of general interest in any topic relevant to the practical applications of biological reactions, whether these are affected by living cells of micro-organisms or plant and animal tissue cultures or by enzyme preparations. Relevant aspects of genetics and cell biochemistry, of process and reactor design, of pre- and post-treatment steps, are included. Contributions from industrial and academic laboratories are equally welcome.

CRYO LETTERS

A monthly journal for the rapid communication within two months of acceptance, of short papers on aspects of low-temperature studies covering the chemical and life sciences and their associated technologies. Editorial comment, diary and reports of meetings and correspondence will also be published. CRYO-LETTERS will be produced at a cost individual scientists can afford and special discounts will be offered to members of appropriate societies.

Clinical Reproduction and Fertility

An important new journal first issue March 1980

Editor

Professor John R. Newton
M.D. M.B. B.S. M.R.C.S. M.R.C.O.G.
Department of Obstetrics and Gynaecology, Birmingham Maternity Hospital, Queen Elizabeth Medical Centre, Edgbaston, Birmingham

Associate Editors

S. Corson *Philadelphia, U.S.A.*
Robert Shaw *Birmingham, U.K.*

Contributors are invited to submit material for publication in the journal direct to the editor at the address above. Subscriptions and requests for further information and specimen copies may be obtained from Blackwell Scientific Publications Ltd, Osney Mead, Oxford OX2 0EL.

Editorial Board

M. Byrgdam *Stockholm, Sweden*
E. Cittadini *Palermo, Italy*
I. Cooke *Sheffield, U.K.*
M. Elder *Hammersmith, U.K.*
M. Elstein *Manchester, U.K.*
V. Gomel *Vancouver, Canada*
W. Jones *Flinders, Australia*
E. Mishell *Los Angeles, U.S.A.*
R. Shearman *Sydney, Australia*
E. Wilson *Otago, New Zealand*
A. Yuzpe *Ontario, Canada*

Clinical Reproduction and Fertility will be published quarterly at £30.00 (U.K.), £36.00 (overseas), $90.00 (U.S.A. and Canada) per annum, post free, including delivery to North America by air.

Aims and Scope

The growth in research on human reproduction and fertility, especially aspects of infertility, has created a need for a new international journal.

Clinical Reproduction and Fertility will publish original papers and invited review articles; it will also include a section on short communications which will be published very rapidly. Initially the journal will be published quarterly but as it is the only journal devoted to the full range of clinical aspects of reproduction and fertility it is expected that the frequency of publication will soon increase. Research on animal models with direct clinical relevance will be included but it is not intended to overlap with the existing journals covering the basic sciences.

EDITING SCIENTIFIC BOOKS AND JOURNALS
An ELSE–Ciba Foundation Guide for Editors
Maeve O'Connor
Senior Editor, Ciba Foundation, London

Following the success of 'Writing Scientific Papers in English' Maeve O'Connor has produced this new guide in collaboration with the Ciba Foundation and ELSE. Scientific editing is beset with problems but there have been few formal texts on either the rudiments of the subject or its finer points. This practical and authoritative book gives guidance in the editing of books, conference proceedings and journals. Written for scientist-editors in all fields of science and medicine, copy editors, publishers of scientific books and journals, any scientist interested in understanding how editors and referees work.

CONTENTS: Editing Outlined; Guiding Authors; Keeping Papers Moving; Working with Referees; Manuscript Editing: creative and substantive editing; Manuscript Editing: Technical editing; Completing Books and Journal Issues; Printing; Reading Proofs; Editing Conference Proceedings: a closer look; Starting a New Journal: financial aspects; Editing a Successful Journal; Editing in the Future: innovation and education.

Atlas of economic mineral deposits

Atlas of Economic Mineral Deposits. By C.J. Dixon. Pp. 143. (Chapman and Hall: London, 1979.) £35.

MINERAL deposits of economic grade represent in all cases abnormal concentrations of the contained elements resulting from unusual combinations of geological processes. This is equally true whether the deposits are of metalliferous ore or industrial minerals, and such deposits are dispersed very thinly through the outer crusts of the Earth. Their bulk is usually small compared with that of the rocks with which they are associated. These fundamental points are implied in Colin Dixon's original and interesting *Atlas*, but they might have received more specific emphasis. His book deals with solid, non-combustible mineral deposits, and bears upon energy sources only in the case of uranium minerals. The deposits with which he is concerned supply, however, most of the raw materials for human artefacts, the manufacture of which is the purpose of the greater part of industry. The *Atlas* is intended as a reference work and a source of descriptive material to accompany a university course. The student of geology whose course includes (regrettably!) no discussion of the useful minerals would also find this a good text to read.

In nine pages of introduction set in three-column format Dixon deals with the generalities of the subject, including prospecting, exploitation, beneficiation and, briefly, the economics of the business; also the scientific aspects including petrology, morphology, and distribution, concluding with a neat summary of the history of genetic interpretation. Some geologists might have been tempted to generalise more about the structural control of oreshoots — the area where the application of geological reasoning has contributed most to industry — but this emerges well enough from the detailed descriptive pages that follow. Here, instead of attempting a comprehensive survey, forty representative major mineral-producing districts are illustrated and summarised, both aspects being ably presented. A very brief list of references accompanies each description forming a tailpiece to the accounts, each of which occupies a double folio of the 240 x 400 mm format. In most cases the drawings, on which a uniform system of symbols is used, are simplified from the published originals, often with great advantage in bringing out the essential points under discussion. Almost all teachers of the subject would agree with the author's contention that the subject needs visual presentation.

The major grouping is fourfold: (1) deposits in environments at the Earth's surface; (2) in sedimentary rocks; (3) associted with felsic magmatic environments; (4) in basic and ultrabasic magmatic rocks. This implies only a loose genetic classification, and wisely so, as it avoids the still-controversial question as to whether the mineral concentrations in sediments were formed in the normal course of sedimentation or not. As the author remarks, a group of French and other continental workers feel strongly that in fact they are so formed, but I am glad that he was not able to think of an English translation of *la gîtologie* for this term seems to me to be very closely associated with this school, the conclusions of which many of us find quite unacceptable in the light, for example, of inclusion homogenisation and stable isotope studies. The compromise proposal which says that minerals concentrated during some later diagenetic episode are sedimentary in origin also seems unsatisfactory to some of us. Mr Dixon wisely avoids confrontation by saying that the terms syngenetic and epigenetic are difficult to apply. His grouping brings together the exogenous deposits in (1) and it is open to those who wish to do so to think that the deposits in groups (2) to (4) derived their energy of formation from processes internal to the Earth's crust and mantle.

The forty examples selected give a good picture of the range of different geological environments in which valuable deposits may become concentrated. The processes involved probably varied as widely as the environments in which they operated. If there is any common factor, surely it is the efficacy of brine as a solvent of metals and other useful elements, whether as sea-water passing through hot basic lavas extruded on the ocean floor, or connate fluid sucked from sediments through cooling felsic magmas, or hypersalines forced out of deep consolidating sedimentary basins. But no single mechanism will cover all possibilities and we should agree with the author that the multiple hypothesis remains unavoidable.

A final section contains five world-distribution maps, and appendices on mineral names, units of measurement and stratigraphic nomenclature. But for the price, I would recommend every student of geology to acquire this book. The hope should be expressed that the unusual shape will not lead to it becoming hidden in obscure corners of college libraries.

Kingsley Dunham

Sir Kingsley Dunham was Director of the Institute of Geological Sciences from 1967-75.

Digging into Wittgenstein

Ludwig Wittgenstein: Remarks on the Foundations of Mathematics. Revised edition. Edited by G.H. von Wright, R. Rhees and G.E.M. Anscombe. Translated by G.E.M. Anscombe. (MIT Press: Cambridge, Massachusetts, and London, 1978.) $27.50.

THIS is a considerably expanded version, in English only, of the book first published under the same title, in English and German, in 1956. It consists, as the editors explain in their Preface, of selections from Wittgenstein's manuscript writings on the philosophy of mathematics from 1937 to 1944, together with nine pages written in 1933-34. It is divided into seven parts, with three appendices to Part I, each part being taken from a different manuscript; but, as the editors make clear, only Parts I and VI reproduce Wittgenstein's text *in toto*, the others constituting selections made by the editors from more extensive writings. The editors express "the opinion that the time has not yet come to print the whole of Wittgenstein's MSS on these and other topics", but give no reasons.

It is now approaching thirty years since Wittgenstein's death; and it is only quite recently that what might be called the philosophical community has come to real grips with the most difficult and profound of his ideas. In that time, much chaff has blown away. The heady excitement of logical positivism, and, after it, of Oxford ordinary language philosophy, can be looked back on only with some embarrassment as intoxication with crudely over-simplified ideas. Wittgenstein's work remains; undeniably, now, that of one of those few philosophers who will be read by all future generations. It is by far the richest twentieth-century source of philosophical ideas, which it will take us more decades yet properly to apprehend and to absorb; despite the difficulty with which his work presents the reader, there is nothing that is likely to be more rewarding. The philosophy of mathematics was one of his earliest and most persistent preoccupations. Originally he planned to include a lengthy discussion of it in the *Philosophical Investigations*, but, being dissatisfied with what he had written, cut almost all of it out; this material comprises Part I of the present book. He was evidently never satisfied with the work he had done in this area of philosophy, and, as the editors remark, did not return to it after April, 1944. The present edition is thus in no sense a finished treatment, or even a unitary book, any more than was the original one: it is a selection from seven distinct pieces of writing by Wittgenstein, with none of which he was content. For all that, it demands the most thorough attention from anyone interested in his philosophy, because the subject occupied so important a place in his thought. He obviously believed that his basic philosophical ideas had profound consequences for the philosophy of mathematics. Precisely what he took these consequences to be is something that the reader has to work very hard to discover.

Wittgenstein's mode of composition was unique. He filled notebooks with 'remarks', a few lines in length, which he continually revised; he would also constantly rearrange the 'remarks' in different sequences to form a disjointedly continuous text. Sometimes the import of the individual remark is luminously clear, sometimes quite obscure: but the method of composition obviously risks leaving the sequence of thought difficult to follow. That it need not have this effect is apparent from the *Investigations*, the only product of his later period that Wittgenstein regarded as a (nearly) finished book: there the final product of years of revision and rearrangement provides a largely continuous treatment of a range of topics, and, given close concentration on the reader's part, expresses with considerable clarity Wittgenstein's conclusions concerning them. Unfortunately, such an outcome to so strange a mode of composition was usually attained only at the final stage: the present book contains seven different sequences of remarks, five of them with omissions made by the editors, and none of them representing a final stage. It is difficult to convey the obstacles which this presents to comprehension without extensive quotation, but perhaps the following brief sequence from Part IV may be regarded as not untypical:

> 37. A human being is *imprisoned* in a room, if the door is unlocked but opens inwards; he, however, never gets the idea of *pulling* instead of pushing against it.
>
> 38. When white turns black some people say "Essentially it is still the same"; and others, when the colour turns a shade darker: "It is *completely* different".
>
> 39. The proposition '$a = a$', 'p p' ['If p, then p'], 'The word "Bismark" has 8 letters', 'There is no such thing as reddish-green', are all obvious and are propositions about essence: what have they in common? They are evidently each of a different kind and differently used. The last but one is the most like an empirical proposition. And it can understandably be called a synthetic *a priori* proposition.
>
> It can be said: unless you put the series of numbers and the series of letters side by side, you cannot know how many letters the word has.

Of course; no-one can be expected to understand the drift of such a sequence torn from its context: but it illustrates reasonably well the difficulties with which the reader has to contend. We have first two striking illustrations: but what exactly they are intended as illustrations of has to be gathered from the whole context in which they are embedded, bearing in mind that, if Wittgenstein had revised his text further, they might have been placed in a quite different immediate context, and bearing in mind also that what is printed here is only a selection, and the editors have not indicated where the omissions occur. There follows, in § 39, what can only be described as a series of musings. None of the observations it contains can possibly be gainsaid: our difficulty is to know what *force* they have. The four propositions are indeed obvious: what connection is this supposed to have with their bearing 'about essence'? What relation do such propositions have to others that are equally 'about essence' but are not at all obvious? In saying that they are 'about essence', is Wittgenstein merely borrowing a term from another philosophy in order to express the priori character which anyone would be likely to see as attaching to all four propositions, or does he have a sharp idea of essence? Do the propositions have *more* in common than what has already been stated, namely that they are obvious and are about essence? They are evidently all different, and differently used: but how great are we supposed to see these differences as being? The third proposition may understandably be called synthetic a priori: but can it justifiably be so called? To obtain any philosophical illumination from a passage like this, the reader must answer all these questions and more: and he must answer them not only to his own satisfaction, but in the manner that it is plausible that Wittgenstein intended them to be answered. As Frege said of his own posthumously published writings, not all of what is contained in this book is gold, but there is gold in it: but, in Wittgenstein's case, the mining operation is particularly arduous.

Michael Dummett

Michael Dummett is Fellow of All Souls College, Oxford, UK.

Geochemical handbook

Handbook of Geochemistry. Vol.2, Part 5: Elements La (57) to U (92). Edited by K.M. Wedepohl. Pp.1546. (Springer: Berlin, Heidelberg and New York, 1979). Looseleaf binder DM690; $379.50.

FOUR years have elapsed since the publication of Part 4 of the *Handbook of Geochemistry*, the longest gap in the production schedule, which has extended almost over a decade from 1969 to 1978. Part 4 is also by far the largest to appear, comprising more than 1500 pages. The original intention of the editorial board was that Volume 2 of the *Handbook* would ultimately contain approximately 2000 pages in four instalments, with publication completed several years ago. The much larger compilation and considerably extended publication time no doubt reflect many factors, not least the rapid growth of geochemical literature and the fact that all authors contributing to the project did not work at the same rate.

The *Handbook* was probably never intended, even in early days, for the individual purchaser. It is expensive to buy, now costing on the subscription price $785.60 (DM 1428.40), including Volume 1, which contained a series of chapters on geochemistry, geophysics and cosmochemistry. Volume 2 is, however, the principal expense. The dollar price for each part has, not surprisingly, risen over the years, but the price in German marks for each part has been held to the level at time of publication.

What does the purchaser receive for his money? In Part 5 he is presented with the pages to complete a large number of the chapters on individual elements, some of which were begun almost a decade ago. Several of these elements, notably phosphorus, sulphur, titanium, chorium, manganese, cobalt, strontium and molybdenum, are important geochemically, and virtually no information has been available for these elements until now in the *Handbook*. Although this lack of data has at times been frustrating, at least there is now the compensation that these chapters are the most up-to-date in the book. Many new pages carrying amendments that include additional information and the correction of scientific and printing errors, are also supplied with Part V.

Of the *Handbook* as a whole, once rearrangement of the entire loose-leaf system — not really a drawback, despite editorial concern — has been completed, the text represents the most comprehensive compilation of geochemical data so far attempted in one publication. The *Handbook* is logical in lay-out, with a high publishing standard of text (and the many tables and diagrams) maintained throughout. As more than 100 authors have been involved in the project, it is inevitable that the style, presentation and depth of coverage between, and even within, chapters will vary. The reader will have to accept this lack of uniformity, just as he will have to accept that much of the text is not up-to-date — the first manuscript was received in 1965. The editorial board now accepts that revision of earlier text to include more recent information is impossible, whatever its members might have felt individually or collectively in the euphoria at the start of the project. They must be relieved it is all over and it is perhaps unlikely that any one of them will embark again on such a large-scale project. The editors and authors should receive the congratultions and thanks of geochemists, first for successfully completing the *Handbook* and second for providing such a valuable authoritative base of data that will make the geochemist's professional life so much easier.

New Russell leadless electrodes fit all pH meters

After extensive development, Russell now introduces a new generation of LEADLESS electrodes which fit virtually all of today's pH meters.

The advanced design incorporates a precision-made connector mounted on the cap of the electrode, which accurately fits the mating lead connector from the pH meter. By fitting the appropriate leads with differing terminations, all Russell Select Range electrodes become compatible with any make of pH meter.

This advanced development in electrode technology now gives total flexibility for the most popular and universally-used electrodes in the Russell range.

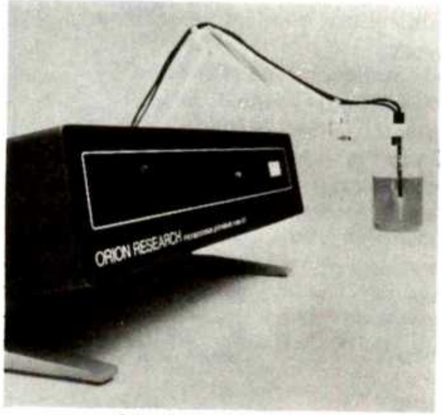
new products: electrodes in analysis

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. For more details use the Reader Enquiry Card bound inside the cover.

A feature on electrophoresis and immunoassay will appear in the 18 October issue.

ORION RESEARCH

The Orion range of ion selective electrodes offers electrodes for some 22 different chemical species, including fluoride, chloride, calcium, potassium, nitrate, ammonium and dissolved oxygen. Orion Research now offer eight new glass electrodes and one reference electrode. The eight sensing electrodes consist of four *p*H, two sodium, and two platinum electrodes for redox and Karl Fischer measurements. These high quality glass electrodes are designed to produce very fast, reliable response. All electrodes are rugged and deliver highly precise measurements time after time. The series provides versatility for a wide range of applications for every laboratory — *p*H, redox and sodium measurement. Included are electrodes for specialised applications. All electrodes are available with standard US connectors. Seven other connectors may be ordered for use with any major manufacturer's *p*H meter.



Orion Research model 811

The Orion model 901 is a digital specific ion meter that incorporates a microprocessor to provide direct readings of concentration. The 901 completely eliminates calibration curves, tables, or calculations in measurements with specific ion and gas-sensing electrodes. Results are calculated in real time and displayed with an accuracy that will satisy the most demanding research application — yet the 901 is simple enough to be used in all quality control applications. Eleven operating modes cover the full range of analytical methods used for performing electrode analyses. Analytical parameters are entered on the digital switches on the control panel, with standardisation and blank correction accomplished at the push of a button. Results are read directly from the LED display in the unit system of your choice.

With only a mode selector and a push-button for standardisation, the model 811 simplifies and automates every step in *p*H measurement except putting the electrode into solution. The microprocessor in the 811 contains a 'look-up' table of NBS buffer values as a function of temperature, ensuring correct *p*H standardisation. Error codes signal whenever an electrode is defective or has a low slope, or if the operator attempts standardisation with the wrong buffer. A stability indicator tells when the displayed reading should be recorded. The output of a platinum resistance thermometer is used to precisely correct sample *p*H readings for changes in temperature. The 1.5 cm high LED display gives readings precise to 0.001 *p*H units. Additional modes allow readings of electrode potential to 0.1mV, electrode slope to 0.1% of theoretical, and temperature to 0.1°C. In the standby mode the 811 becomes a digital clock. Other features of the meter include BCD output, Karl Fischer polarising current, and recorder output. Measurement with specific ion and gas sensing electrodes can be made using calibration curves, known increment tables, or titrations.

Circle No. 86 on Reader Enquiry Card.

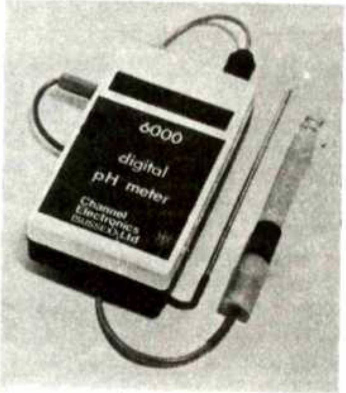
BORO LABS

Boro Labs of Aldermaston offer two distinct ranges of *p*H meters. For the user whose requirement is high accuracy, reliability and reproducibility Metrohm Ltd of Herisau produce instruments with both analog and digital readout systems, from a pocket size unit weighing only 450 g up to precision research instruments offering accuracy of 0.01 *p*H. Uniprobe *p*H meters offer economically priced, mains or battery powered accurate and reliable instruments, for both laboratory and field applications. They are particularly suitable for industrial use where the quality of their controls and the heavy duty case will withstand semi-skilled operation and considerable physical abuse. Boro Labs are also agents and stockists for the wide range of competitively priced *p*H electrodes manufactured by Russell *p*H of Auchtermuchty and can offer rapid delivery of the more popular types.

Circle No.87 on Reader Enquiry Card.

CHANNEL ELECTRONICS

The 6000 series of hand-held battery-driven *p*H/temperature meters from Channel Electronics (Sussex) Ltd offers fast and accurate measurement of both 0–14 *p*H, and temperature over the range -30°C to +150°C. Housed in a robust injection moulded case with 10.2 mm height LED readout the series is available in three basic models. The 6060 provides *p*H measurement to a resolution of 0.1 *p*H and the 6080 to a resolution of 0.01 *p*H. Temperature on both instruments is to a resolution of 1.0°C. A third instrument, the Model 6090 offers -999 to +999 mV with a resolution of 1.0 mV. Models 6060 and 6080 are supplied complete with combined plastic bodied *p*H electrode and steel bodied temperature compensation/measurement probe. Using standard MN1500 (manganese alkaline) batteries the 6000 series permits up to 35 h of continuous use or 60 h intermittent use. The instrument can be provided with type AA rechargeable cells plus a mains recharger unit. A further option is a carrying case with a separate pocket for the probes.



Other products from Channel Electronics include the model P101 portable *p*H meter for rapid determination of *p*H and millivolts. The 101 operates from two small universally obtainable batteries and features a chart recorder output socket. The MP 100 *p*H chart recorder is a miniature galvanometer chopper-bar recorder developed to provide a permanent record of *p*H level when used in conjunction with a *p*H meter having a d.c.output. The recorder has a calibrated chart width of 59 mm and is available with a choice of chart speeds of between $\frac{1}{12}$ and 480 inches per hr. The instrument is extremely rugged and has been designed for reliability, requiring no routine attention other than replacing the chart roll. The unit is available in a.c. or d.c. versions with a self-contained d.c. package for field use.

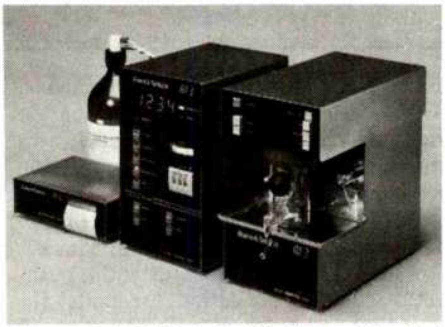
BAIRD & TATLOCK

The new AF3 direct reading Karl Fischer titrator from Baird & Tatlock utilises modern computer technology and a controlled impulse metering pump (instead of the usual burettes) as the two principal elements of a fully-automated, push-button system. (1) The AF3 comprises two basic modules:- The metering module which houses the pump and liquid handling system, and automatically takes the correct volume of reagent straight from a standard 1 or 2 litre Winchester bottle. No reservoir bottles, volumetric glassware or syringe burettes are involved. And (2), the titration module, which contains the electronics and main controls, automatically displays the results directly as a digital readout in mg of water to the nearest 0.11 mg. No time consuming calculations are involved. An ancillary printer unit is available as an optional extra. Apart from the major advantage of offering a direct water content display without calculation, the auto metering system also provides many other operational benefits. A 'standby' facility enables the titrator to be kept in a 'neutral' condition immediately ready to titrate any sample offered to it. Sensors set up fault alarms and take appropriate action if the titration vessel becomes overfilled or reagent is spilled on the operating platform. A special timer computes metering pump operation and gives warning of routine replacement. 'Prime' and 'Clear' buttons enable the unit to be brought into operation rapidly, and just as easily closed down at the end of a working period. A low voltage magnetic stirring facility gives constant speeds under all conditions. All results are fully compatible with earlier Karl Fischer titrometic units.



The new Baird & Tatlock AF3 direct reading Karl Fischer titrator

KANE-MAY LTD

Advances in microelectronics have made possible an extremely reliable pocket-sized, digital pH meter, the Accuchem, manufactured by Kane-May Ltd. Accuchem allows for the instantaneous measurement of pH values over the full scale of 0 to 14 pH with a 0.01 resolution. This portable pH meter provides large 13-mm readings on an LCD display. Operating from a single 9 V PP3 battery, the Accuchem will allow field use for well over 100 h continuous operation. The instrument is available with a rugged combination electrode which is designed to withstand hard industrial and site use. A small unbreakable carrying case contains both the instrument and electrode.

Scientific findings challenge EPA ban

DEBATING SCIENTISTS OF 8 NATIONS AGREE PESTICIDE 2,4,5-T IS SAFE!

- *poses no cancer hazard to humans or animals*
- *does not cause abortions in women (as claimed)*
- *poses no practical environmental harm*

Safe...that's the consensus of 59 scientists. Top world experts on pesticides who journeyed to Washington, D.C. recently from seven countries and 20 U.S. States to 'dispute and resolve' the controversy surrounding the currently banned 2,4,5-T, the pesticide widely used to protect forests, cattle and weeds.

Scientific findings of the unique, first-of-its kind Dispute Resolution Conference sponsored by the American Farm Bureau Federation run counter to the position of the Federal EPA which placed a temporary ban on most uses of the pesticide in March.

To those who still believe 2,4,5-T should be banned we commend the just released Conference report. Especially the scientific conclusion on the Alsea, Oregon epidemiology study on which the EPA based its action to ban. The scientists agreed that the report has such deficiencies that no conclusions are possible with regard to alleged abortion-causing effects of 2,4,5-T.

We compliment the scientists who took the necessary time to resolve issues now restricting the use of this important agricultural tool. The participants came from the fields of medicine, toxicology, chemistry, ecology, agriculture. They represented the scientific concern of Canada, Italy, Sweden, New Zealand, Switzerland, France, Germany and the U.S.A.

But we wonder why many of the ever-vocal minority who seek a final end to the use of 2,4,5-T and other pesticides *declined to attend* or to join in the scientific dispute ... certainly an ideal forum for arguing their case with the world's scientific experts.

The full Dispute Resolution Conference report has been mailed to Members of Congress and other government officials ...we urgently direct their attention to this decisive, truly scientific consensus ...that 2,4,5-T is safe when properly applied.

It's important to understand that there is still no *scientific* reason to prevent the pesticide's use by literally hundreds of thousands of Americans who have depended on it for 30 years...in growing their crops, cattle, timber. For more information on the Conference findings, write American Farm Bureau Federation, 225 Touhy Ave., Park Ridge, IL 60068.

SEMAT

Semat (UK) now offer both digital and analog *p*H meters available with a wide range of compatible electrodes. The digital meters are available in LED or LCD forms and are designed for both laboratory and field work.

The CD60 with its 13-mm liquid crystal display provides an accuracy of 0.02 *p*H units when used with a standard electrode. Battery powered, and provided with a tough, durable carrying case, the CD60 is a compact, simple to operate instrument ideally suited to outside measurements, yet its versatility allows equal application to laboratory work. Attachment of the PS100 adapter converts it to mains operation. For *p*H and/or mV work, Semat produce the CD300. Push button controls on the front panel select the readout range to be either 0 to 14 *p*H, 0 to 999mV or 0 to 9.99V. Temperature compensation and buffer standardisation are provided with simple slider controls which are also front panel mounted.

SEMAT CD300 combination digital pH/mV meter

Semat (UK) also stock a wide range of electrodes including glass, reference, combination, general purpose and gel filled, all compatible with any of their meters. They are happy to advise on any *p*H related problem and assist in optimum electrode choice.

Circle No. 91 on Reader Enquiry Card.

EDT RESEARCH

The ATC 700 automatic titration system from EDT Research comprises a motor-driven burette, analytical cell with sensor and automatic sample changer all connected to a microprocessor-based control console. The instrument is capable of performing repetitive titrations, using potentiometric sensing, completely unattended with high precision and accuracy. It is extremely simple to operate, having very few external controls, and the microprocessor takes care of sample selection, titrant addition, endpoint detection and results display and print-out. The titrator has been designed specifically for use with ion-selective electrodes to make allowance for the somewhat slower responses of these sensors. Various error detect functions within the instrument will inhibit analyses if the indicator or reference electrodes are malfunctioning, thus eliminating the possibility of incorrect results. The ATC 700 can be used for a wide variety of analyses including: acid-base titrations using strong or weak acids and bases; precipitation titrations such as chloride and sulphate determinations; complexometric titrations such as calcium, magnesium and zinc determinations; and redox titrations such as iron and permanganate measurements.

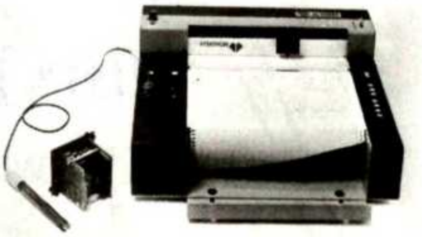
VITATRON

A novel product in the *p*H field is the Vitatron model 2001 chart recorder, which can be supplied with the high impedance input module which will accept direct input from a *p*H electrode, without the need for a *p*H meter. The signal which drives the 2001 enters via an input module, which is plugged into the recorder chassis. A variety of input modules is available, including the new *p*H input module. This will take a combination *p*H electrode fitted with a BNC plug. The recorder reads *p*H from zero to 14 across the chart, and there is an expanded *p*H range of 3 *p*H units for more precise measurements. To obtain the 2001 recorder brochure detailing this technique, circle the number below.

Circle No.93 on Reader Enquiry Card.



Vitatron 2001 chart recorder with pH electrode

TECATOR

A new analyser — Striptec — for precise trace metal determinations is being introduced by Tecator. Striptec uses new technology that gives a very large dynamic measuring range, with no special preparatory steps. The instrument is capable of simultaneous measurements of several metals with high precision at very low concentrations (parts per 10^9. Typical applications are tap water, waste water, seawater, beverages, wine and urine. In combination with Tecator's programmable digestion systems for multi-sample preparation Striptec allows convenient and reproducible conditions for the measurement of metals not only in liquids and inorganic materials, but also in all kinds of food-materials.

Circle No.94 on Reader Enquiry Card.

The Striptec system: electrode stand, processing unit and recorder

RUSSELL

The Scottish-based *p*H electrode manufacturer, Russel *p*H, are improving supply and service to customers in the South of England through an arrangement with Semat (UK) who will stock and market the Russell electrodes range. Semat are now able to supply from stock, both instruments and electrodes as a complete package. A further advantage will be an ability to supply replacement electrodes for all makes of *p*H meters whether of British, European or American manufacture due to the wide and versatile range produced by Russell *p*H. This range includes glass single and combination electrodes, low-resistance electrodes having very fast response, and reference, metal and polymer-bodied types.

As well as laboratory electrodes, units for industrial plant applications are also available including disposable and replacement combination types, and last but not least, the Select range of lead-less electrodes recently released. These lead-less electrodes are fitted with a precision-made moisture proof cap/socket arrangement and utilise a mating plug/cable assembly supplied with correct meter termination(s). This lead once fitted to the *p*H meter becomes a permanent fixture and greatly simplifies subsequent electrode replacement.

Two of the range of Karl Fischer titrators from Metrohm.

BRINKMANN

Brinkmann Instruments Inc. a subsidiary of Sybron Corporation now have available a new brochure describing five Metrohm Karl Fischer titrators which perform moisture determinations efficiently. These titrators can provide every laboratory with the versatility it needs at a low price, whilst maintaining quality, accuracy and precision. All models measure moisture concentrations as low as 10 p.p.m. and as high as 100%, perform back titrations, feature 'snap-in' burette units for rapid change of solvent and reagent, and use specially designed titration vessels that allow sample introduction without exposure to atomspheric moisture.

Circle No. 96 on Reader Enquiry Card.

METTLER

Electrodes are used as indicators in the Mettler range of automatic titrators. The latest product in the range is the model DL40 MemoTitrator, a microprocessor controlled instrument with 10 different titration modes and extensive computation facilities. The 10 modes include titrations to a pre-selected endpoint (absolute or relative), equilibrium titrations, recording titrations, incremental titrations, Karl Fischer determinations, precision dispensing, *p*H and *p*X measurements, back titrations with automatic calculation of results, manual titrations and automatic electrode calibrations. Endpoints can be indicated by potentiometric, voltammetric or photometric sensors. By connecting an electronic analytical or top-loading balance, and a printer or recorder, a complete titration station can be set up in a minimum of space. One novel function is

NICKTRANSLATIONSYSTEM

The world's first. Packaged complete.

Naturally it is more convenient than assembling the components yourself. But even more important is its reliability.

For example, the *E. coli* DNA Polymerase I is prepared in our laboratories to ensure extremely high reproducibility. The dCTP, [α-^{32}P]- is tested for nick translation by our Biological Testing Laboratory. (Typical incorporation is 40%, and we guarantee 1 x 10^8 dpm/μg DNA.) The supercoil pBR322 Plasmid DNA control we use to test each lot of systems is included so you can check yours. Finally, the DNAse I, dNTP mixture, stop-buffer, and sterile deionized water are optimized for compatibility and stability. Approximately twenty assays can be run.

A bulletin describing this exclusive system is yours for the asking.

The new, easy and economic way to make precise heavy metal determinations even at super-low concentrations

triptec – the latest development from Tecator – ses new technology (potentiometric stripping nalysis) that gives a very wide measuring range, ith no special preparatory steps. The nstrument is capable of simultaneous easurement of several metals including admium, lead, copper with high precision also t ppb-levels.

In combination with Tecator's programmable igestion Systems for multisample preparation triptec allows convenient and reproducible onditions for the measurment of trace metals not nly in liquids and inorganic materials, but also n all kinds of organic materials.

Compared to existing analyzers, Striptec is more compact and less expensive. It offers great advantages in being simple to install and operate. The robust design and unique technology offer troublefree maintenance and minimize the service demand.

Step forward with the latest development from Tecator!

DL40 Memo Titrator

the instrument's 'learn' mode. If the operator is not sure of the best method of titration, the MemoTitrator can be asked to suggest a method. This is done by subjecting the sample to a special incremental titration in which its approximate content, the best possible titration principle and the optimum parameters are determined.

Mettler also offer the model SR10, a fully automatic instrument into which operators can load up to 96 samples for analysis by a choice of four types of titration. Once set up, the instrument works automatically and without attention. Though endpoints in automatic titration are normally sensed by electrodes, there is often a need to use a colour change as indication, and Mettler have recently introduced the model DK18/181 Phototitrator. This is a scanning instrument which can be used throughout the visible spectrum to respond to endpoint colour changes, using the results to control any automatic titrator from the Mettler range.

MSE

As agents in the UK for Orion Research and Mettler, MSE Scientific Instruments can offer a wide choice of analytical methods using electrodes. New to the UK is the Mettler DL40 MemoTitrator which features a facility for storing the parameters necessary for 10 standard titration modes. The Orion range includes the SS20 ionised calcium analyser and type SS30 sodium and potassium analyser for blood determinations, and the 417 skin chloride analyser. A recent introduction from Orion is the GX series of epoxy-body 'unbreakable' gel-filled electrodes.

MSE can supply the module required to convert Vitatron 2001 chart recorders to use as a continuous monitor of *p*H by direct link to a *p*H electrode. This module is also available fitted with a suitable electrode, such as the Orion model 9005.

Circle No. 98 on Reader Enquiry Card.

PROBION

Probion Ltd are able to produce specially constructed *p*H glass probes made of high quality membrane glasses at reasonable cost. New advances in the design of autoclavable *p*H combined glass-reference electrodes have now made it possible to sterilise the *p*H sensors *in situ* at high temperatures. Probion also market a wide range of *p*H electrodes which can be used with any *p*H equipment of whatever make. Some are capable of measuring samples as small as 20 ml, others — sheathed in inert plastic — have an immersion length of 2 m. Recent developments include miniature probes for use in isoelectric focusing gels, and glass probes for the measurement of P_{CO_2} and dissolved oxygen.

Probion collaborate closely with their customers in developing *p*H electrode systems for specialised uses.

BECKMAN

Beckman have introduced three new SelectIon analysers for fast, accurate ion-selective measurements. The product range now includes the three new analysers, more than 20 electrodes, and related supplies and reagents. Each of the instruments measures specific ions down to fractional milligrams per litre concentrations. Electrodes are availble to measure ammonia, bromide, cadmium, calcium, carbon dioxide, chloride, copper, cyanide, fluoride fluoroborate, hydrogen, iodide, lead, nitrate, nitrogen oxide, perchlorate, potassium, silver, sodium, sulphide, thiocyanate and water hardness. Beckman plan to add more electrodes at later dates.

The new SelectIon analysers from Beckman

SelectIon systems are especially suited for applications in water purification, sewage treatment, plating, agriculture, food processing and analysis, and biomedical research. The SelectIon range includes the SelectIon 5000 ion analyser, a microprocessor-based instrument; the SelectIon 2000, an analog instrument; and the Monitor II system, a rugged portable analyser. The research-grade SelectIon 5000 ion analyser features computer programming that displays words and symbols to communicate with the user to make operation simple. It signals when steps are forgotten or errors are made. Specific ion computations are done automatically, and final answers are digitally displayed. Steps such as standardisation and calibration are simple push-button operations. A printer out-put enables permanent recordkeeping and sequential step recording. The SelectIon 2000 combines advanced electronic test circuits with ion-selective operations for several routines for direct concentration measurement as well as *p*H, expanded-scale *p*H and mV. Multiple controls on the analyser provide fine tuning of determinations for increased accuracy. The SelectIon 2000 uses all ion-selective electrodes through sensitivity and polarity changes. Because of wide-range standardisations, silver or sulphide electrodes with large potential offsets can be used. Two-point calibrations can be made with standardisation at any point on the scale. The slope control allows calibration for direct concentration readout and provides sensitivity change for different electrode responses. A midscale value control lets the user shift the calibrated range without re-calibrating. The SelectIon 2000's expanded *p*H and mV readout mode increases accuracy. Its absolute mV mode performs titrations easily. The mirror-backed analog display helps the user to anticipate endpoints. Another significant feature is the electronic test circuit that verifies proper instrument function.

The Monitor II system is a fully portable unit designed for factory, laboratory or field applications.

DAGAN

The first commercially available single electrode voltage clamp, current clamp and pre-amplifier is now available from Dagan Corporation of Minneapolis. Pictured is the model 8100 single electrode system. Voltage clamping is one of the most powerful methods available for studying the electrical events occuring in cell membranes. Voltage clamping with a single electrode is accomplished by alternating between record and voltage or current maintenance modes. Use of a single electrode eliminates the difficulties of a second electrode such as maintaining a healthy cell or electrical coupling, and also, the minute cell size might dictate the use of only one electrode.

GENERAL RELATIVITY AND COSMOLOGY
Professor J.V. Narlikar

A critical analysis of General Relativity as applied to Cosmology written by one of the world's leading astrophysicists.

It presents a thorough survey of current cosmological theories, including a brilliant examination of recent controversies and a lucid exposition of the authors own contributions to the field.

This is a pioneering work which will bring the reader up-to-date with developments made in a field which has been increasingly active since Einstein first proposed his General Theory of Relativity.

Contents:
Theories of gravitation – Vectors and Tensors – Tensor Calculus – Space-time Curvature – Space-time Derivatives – Energy-momentum Tensors – The Einstein Equations of Gravitation – The Schwarzchild Solution – The Experimental Tests of General Relativity – Strong Gravitational Fields – Cosmology – The Friedmann Models – The Steady State Theory – Observational Tests in Cosmology.

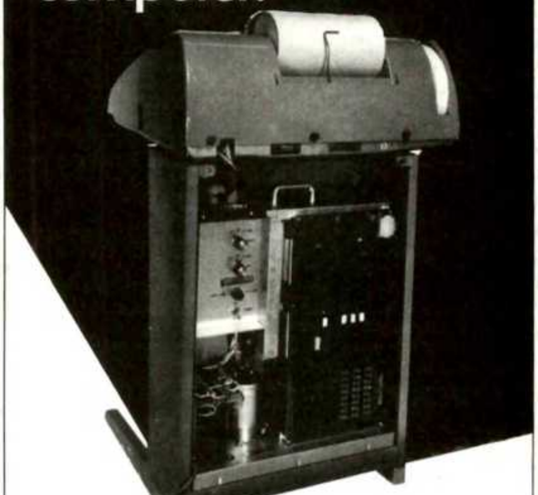
M MACMILLAN PRESS

CONVERT
a simple terminal into a powerful, programmable computer!



It's accomplished by the new IN/US 5000 Micro-Computer

With the IN/US 5000, a simple terminal becomes a powerful programmable computer at a price that fits even the tightest budget. The IN/US 5000 is directed primarily to bio-medical laboratories with liquid scintillation and/or gamma counting systems. But, it can be used with any measurement system—new or old—outputting serial data to a typewriter, lister or terminal. This means you can upgrade existing equipment inexpensively. If you're shopping for a system, the Model 5000 will complement new "low cost" units by providing more advanced data treatment than possible with the latest top-of-the-line counters. And for those not yet into programming, a selection of turnkey programs is provided. The result . . . .

A **far more** advanced configuration at a cost that is **far below** what is otherwise possible.

ROTH SCIENTIFIC

Metrohm automatic titration equipment is supplied by Roth Scientific of Farnborough, Hants. Systems available include the type E576 automatic potentiograph in series with an E365B Conductoscope and E575 Dosimat, and the E535 general purpose Multidosimat coupled to an E549 titration stand and the E518 conductivity meter in series with E576 Potentiograph. Metrohm automated titration equipment provides proven reliability, accuracy and speed of handling for titrimetric reactions.

Circle No.102 on Reader Enquiry Card.

RADIOMETER

In August Radiometer of Copenhagen announced their new "80 Series", range of titration equipment which is a completely integrated modular system offering many different approaches to your titration problems. The Series 80 begins with simple endpoint systems through to curve recording (including first differential) on to sophisticated microprocessor controlled endpoint searching systems (plus curve print-out as an option). Other features are automatic sample preparation and presentation for single or multiple end-point determinations (including back titrations), so complete automation is possible. Series 80 systems are interchangeable with the 60 Series systems currently in use. The major advance in the Radiometer system has been the introduction of the ABU 80 microprocessor controlled Autoburette. Simply slide in the correct burette in its easy-load cartridge and the ABU 80 takes over automatically setting the stop-cock to the correct position and following a pre-programmed routine to fill and purge the burette ready for use. At the push of a button any of the burette modules (2.5 ml, 10 ml and 25 ml) can be made to operate at 1/10 of their normal operating volume, giving the operator a very wide choice of working volumes. All glassware and liquid flow systems are easily accessible but kept under cover protecting them from accidental damage or the effects of light. A large clear LED volume display with automatic decimal point setting gives clearly visible, unambiguous readings. The ABU 80 will 'stack in' with the other modules leaving the maximum possible bench space to work on.

Circle No.103 on Reader Enquiry Card.

INSTRUMENTATION LABORATORY

The new I.L.617 Blood Gas Laboratory provides the blood gas data vital to advanced patient care. The two major components of blood gas analysis — acid/base status and oxygen status — are both analysed comprehensively. For the rapid assessment of acid/base balance, the I.L.617 determines and prints out *p*H, P_{CO_2}, base excess, total CO_2 and bicarbonate. To clearly define oxygen status, it provides P_{O_2}, total haemoglobin, % oxyhaemoglobin, % carboxyhaemoglobin, % methaemoglobin and O_2 content. Operation is simple — you present blood to the system and approximately 90 s later all data is printed out in as many copies as you wish. Cleaning and recalibration cycles follow automatically.

Meetings

27-28 September, **Annual Meeting of the Society of Low Temperature Biology,** London (Dr B. Fuller, Academic Department of Surgery, Royal Free Hospital, London NW3, UK).

8-10 October, **6th Biennial Symposium on Turbulence,** Rolla (Norma Fleming, Coordinator Continuing Education University of Missouri-Rolla, Rolla, Missouri 65401).

17-19 October, **The Use of Microprocessor-Based, 'Intelligent' Machines in Patient Care,** Maryland (Dr Henry S. Eden, Department of Health, Education and Welfare, Public Health Service, National Institutes of Health, Bethesda, Maryland 20014).

18 October, **Fracture Mechanics,** London (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

30 October, **Onshore Exploration and Production in the United Kingdom,** London (The Secretary, The Institution of Mining and Metallurgy, 44 Portland Place, London W1, UK).

4-11 November, **10th International Congress of Allergology,** Jerusalem (Dr Israel Glazer, Chairman, Organising Committee, 10th International Conference of Allergology, Tel Aviv, Israel).

6-7 November, **The Impact of New Technologies on Publishing,** Luxembourg (J.M. Gibb, Commission of the European Communities, DG X111, P.O. Box 1907, Luxembourg).

5 December, **Electric Arc Steelmaking for the 1980's,** Sheffield (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

11-12 December, **Environmental Effects of Utilising More Coal,** London (Council for Environmental Science and Engineering, Conference Office, c/o The Institute of Biology, 41 Queen's Gate, London SW7, UK).

1980

23 January, **The Integrity of Sprayed Coatings,** Birmingham (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

10-14 February **EMBO Workshop of Drug Receptors in the Central Nervous System,** Rehovot (Mrs Chava Bohak, Secretary, EMBO Workshop, Department of Neurobiology, The Weizman Institute of Science, Rehovot, Israel).

27-28 March, **13th International TNO Conference on Biotechnology,** Rotterdam (TNO Information Department, 148 Juliana van Stolberglaan, 2595 The Hague, Holland).

31 March-3 April, **Envirpnmental Degradation of High Temperature Materials,** Isle of Man (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

11-15 April, **Internation Conference on Endosymbiosis and Cell Research,** Tübingen (Dr W. Schwemmler, Freie Universität Berlin, Institut für Pflanzenphysiologie und Zellbiologie, Königin-Luise-Str. 12-16a, BRD 1000 Berlin 33, DDR).

13-17 April, **Neurological Mutants Affecting Myelination. Research Tool in Neurobiology,** Seillac (Dr N.A. Baumann, Laboratoire de Neurochimi INSERM U.134, Hôpital de la Salpêtrière, 47 bld de l'Hôpital, 75634 Paris Cédex 13, France).

23-27 June, **Conference on Precision Electromagnetic Measurements,** Braunschweig (Professor H. Capptuller, Physikalisch-Technische Bundensanstalt, Bundesallee 100, D-3300 Braunschweig, FRG).

8-11 September, **6th International Conference on Gas Discharges and their Applications,** Edinburgh (The Press Office, Institute of Electrical Engineers, Savoy Place, London WC2, UK).

7-12 September, **IUPAC International Symposium on Macromolecules,** Florence (Fondazione Giovanni Lorenzini, Via Monte Napoleone 23, 2021 Milan, Italy).

8-10 September **Photoelectrochemistry discussion,** Oxford (Dr M.D. Archer, Department of Physical Chemistry, University of Cambridge, Lensfield Road, Cambridge, UK).

8-11 September, **Dielectrics conference,** Canterbury (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

8-12 September, **5th International Symposium on Inhaled Particles,** Cardiff (D.A. Phillips, Joint Organising Secretary, MRC Pneumoconiosis Unit, Llandough Hospital, Penarth, Glamorgan, UK).

8-12 September, **7th World Conference on Earthquake Engineering,** Instanbul (Aybars Gürpinar, Secretary 7 WCEE, Yüksel Caddesi 7/B, Ankara, Turkey).

9-11 September, **3rd IMA Conference on Control Theory,** Sheffield (Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex, UK).

10-12 September, **Cellular Responses to Mutagens and Carcinogens,** Brighton (Prof. R.J. Cole, (B.S.C.B./U.K.E.M.S. Symposium), University of Sussex, Falmer, Brighton, UK).

15-19 September, **10th European Solid State Device Research Conference,** York (The Institute of Physics, 47 Belgrave Square, London SW7, UK).

15-19 September, **3rd International Symposium on Loss Prevention and Safety Promotion in the Process Industries,** Basle (P.O. Box 141, CH-4007 Basle, Switzerland).

17-19 September, **Eurotunnel '80, Conference,** Basle (The Secretary, Institution of Mining and Metallurgy, 44 Portland Place, London W1, UK).

18 September-2 October, **International Symposium on Forest Seed Storage,** Ontario (Ben Wang, National Tree Seed Centre, Petawawa National Forestry Institute, Ontario, Canada).

22-28 September, **3rd International Colloquium on Physical and Chemical Information Transfer in Regulation of Reproduction and Ageing,** Varna (Dr J.G. Vassileva-Popova, Department of Biophysics, Bulgarian Academy of Sciences, 1113 Sophia, Bulgaria).

22-27 September, **International Practical Post-Graduate Course on Pain Therapy,** Vicenza (Dr Ruggiero Rizzi, Ospedale Regionale, 36100 Vicenza, Italy).

23-25 September, **1st International Conference On-Line Surveillance and Monitoring of Plant Integrity,** London (Miss J Bovier, Conference Secretariat, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

24-28 September, **EMBO-EMBL Workshop, on X-Ray and Neutron Scattering of Biological Structures,** Hamburg (Professor H. Stuhrmann, EMBL c/o DESY, Notkestrasse 85, D-2000 Hamburg 52, FRG).

26-28 September, **Inorganic and Organic Pollutants in the Troposphere and Natural Waters,** Belfast (W.J. Swindall, Department of Chemistry, The Queen's University, Belfast, UK).

29 September-3 October, **Assembly on Current and Future Oceanography,** Massachusets (Dr P.G. Brewer, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543).

6-10 October, **5th International Conference on Small Angle Scattering,** Berlin (Professor R. Hosemann, Fritz-Haber-Institut der MPG, Teilinstitut fur Strukturforschung, Faradayweg 4-6, 1000 Berlin 33, E. Germany).

1981

17-19 March, **International Conference on Telecommunication Transmission,** London (Institution of Electrical Engineers, Savoy Place, London WC2, UK). WC2, UK).

5-11 July, **6th International Conference on Protozoology,** Warsaw (Dr S.L. Kazubski, Department of Cell Biology, M. Nencki Institute of Experimental Biology, 3 Pasteura Street, Warsaw 22, Poland).

IODINE-125
For protein iodination

NEW!

Now
Reduced exposure
Reduced contamination risk
With new exclusive packaging
AMERSHAM'S IODINE SHIELD*

Reduced exposure
The new packaging consists of 2 parts:
- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk
The cap of the plastic outer container is keyed so that when inverted it is used to unscrew the cap of the inner vial — no need to handle this vial at all from start to finish.

A safety innovation from the World's Leading Supplier of Radioactive Materials.

ICE AGES

M

: Solving the Mystery
Professor John Imbrie and Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

APPOINTMENTS VACANT

UNIVERSITY OF BRISTOL

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

POSTDOCTORAL ASSISTANT (Range 1A)

funded by an M.R.C. Project grant to study the biosynthesis of the erythrocyte membrane anion transport protein. The project will investigate the mechanism of incorporation of this integral protein into membranes, both in intact cells and in an mRNA-dependent cell free protein synthetic system. Applicants with previous experience in the area of nucleic acids and protein biosynthesis preferred. The post is for 3 years at a salary of £4,910 to £5,199 to £5,480 per annum. (Scale effective from 1st October, 1979 and subject to further review). The post will be available from October/November 1979.

Applicants should send their curriculum vitae and the names of two academic referees as soon as possible to Dr M.J.A. Tanner, Department of Biochemistry, University of Bristol, Bristol BS8 1TD. 3239(A)

SIMON FRASER UNIVERISITY

Burnaby, British Columbia, Canada.

DEPARTMENT OF BIOLOGICAL SCIENCES

DIRECTOR OF MASTER OF PEST MANAGEMENT PROGRAM

Applications are invited for the vacant position of Director of the Master of Pest Management (MPM) program and related activities at Simon Fraser University.

The appointment will be at the rank of Associate Professor or Professor, with level and salary commensurate with training and experience. The successful candidate should have an established professional and academic reputation in pest management and a current research program in at least one aspect of pestology. Responsibilities will include the development and organisation of the MPM program as well as research and teaching in the individual's area of expertise. The position is available as of 1 September, 1979, subject to budgetary approval. The current salary range for the Associate Professor and Professor rank is, respectively, $25,636 to $41,018 and $31,552 to $55,216 per annum.

Applications, including an up-to-date curriculum vitae, copies of representative recent publications and the names of at least three referees, should be sent to: Dr M Mackauer, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, BC, Canada, V5A 1S6 from whom further information may be obtained. Applications will be received until 31 October, 1979 or until the position is filled. W341(A)

POPULATION GENETICIST

The Department of Biology at the University of California, Riverside invites applications for a faculty position in population genetics beginning September 1, 1980. Candidates must have evidence of ability to initiate and sustain a productive, high-quality research program and show enthusiasm and skill in teaching at both the undergraduate and graduate levels.

Teaching duties may include introductory biology, genetics, and upper division and graduate courses in population genetics. Appointment will be made at the Associate Professor level. Applicants should send curriculum vitae, statement of teaching and research interests, reprints and letters from three referees.

The University of California is an equal opportunity and affirmative action employer. Applications are invited from all qualified individuals, especially women and members of minority groups.

Send applications to: Professor R. Ruibal, Chairman, Department of Biology, University of California, Riverside, California 92521. W 370(A)

UNIVERSITY OF NEWCASTLE UPON TYNE AND NEWCASTLE AREA HEALTH AUTHORITY (Teaching)

CHAIR OF EXPERIMENTAL NEUROLOGY in the DEPARTMENT OF NEUROLOGY

Applications are invited for the Chair of Experimental Neurology, which is endowed by the National Fund for Research into Crippling Diseases. Medically qualified applicants should hold a higher medical degree and have extensive research experience in adult or paediatric neurology or in neuropathology or in related disciplines, preferably of particular relevance to neuromuscular disease. The appointment will take effect from 1st March 1980 or as soon as possible thereafter.

The successful candidate, if a registered medical practitioner, will be accorded Honorary Consultant status with the Newcastle A.H.A. (T). Salary in accordance with the Professorial (Clinical Consultant) or Professorial (Non-Clinical) scales, with membership of the appropriate University superannuation scheme.

Further particulars may be obtained from the Senior Assistant Registrar, The Medical School, University of Newcastle upon Tyne, Queen Victoria Road, Newcastle upon Tyne, NE1 7RU, with whom applications (15 copies) giving the names of not more than three referees, must be lodged not later than 31st October, 1979.

(Applicants from outside the British Isles may submit one copy only). 3218(A)

THE POLYTECHNIC OF NORTH LONDON

DEPARTMENTS OF SCIENCE AND TECHNOLOGY

RESEARCH ASSISTANT VACANCIES

There are possible vacancies for Research Assistants in the following areas: Biology, Chemistry, Computing, Geology, Polymer Science and Technology, Physics, Statistics.

Candidates should have a good honours degree in a relevant subject. Research Assistants are required to assist with the teaching of the Polytechnic for up to six hours per week and normally register for a higher degree of the CNAA.

Salary Scale: £3,087 to £3,261 inclusive of London Allowance (under review).

Application forms and further details may be obtained from the appropriate Head of Department. 3244(A)

OXFORD UNIVERSITY

DEPARTMENT OF BOTANY & LABORATORY OF MOLECULAR BIOPHYSICS

Applications are invited for the post of Research Assistant grade 1A supported by a grant from the Agricultural Research Council for research into the structure of ribulose bis-phosphate carboxylase (RuBPC). The grant is for three years starting on 1 November 1979 and the salary will be £5,048 to £5,321 to £5,591. The applicant should have obtained his PhD or DPhil and should already be familiar with enzymological and physical chemical methods. The successful applicant's work will be to isolate and crystallise RuBPC for X-ray structure analysis.

Applicants should apply in writing by 12 October to the Administrator, Botany Department, Oxford University, South Parks Road, Oxford, and include a curriculum vitae and the names of two referees. 3250(A)

Public Health Laboratory Service

Deputy Curator

(Principal Grade Microbiologist)

National Collection of Type Cultures Central Public Health Laboratory, Colindale

Colindale Avenue, London NW9 5HT

Applications are invited from experienced science graduates in Microbiology, preferably with a higher degree, for the whole-time post of Deputy Curator. The primary function of the NCTC is to hold and supply authenticated bacterial cultures of medical or veterinary importance for education, control, assay, taxonomic and other purposes to PHLS laboratories, Universities, Medical Schools, Hospitals and Industry. Other functions include the provision of an identification service for bacteria of medical relevance that are difficult to classify, research on bacterial taxonomy and the provision of freeze-drying facilities for other PHLS laboratories.

The total staff establishment is 23. The Deputy Curator will assist the Curator in directing and developing all aspects of NCTC work.

Further details of the post are available from the Curator (Dr. L.R. Hill) and the laboratory may be visited by arrangement (Tel. 01-205 7041. extension 236).

Salary: Principal Grade Microbiologist £7,995 to £10,458 + £354 London Weighting, increasing to £9,129 to £12,306 + £354 London Weighting on 1 January, 1980. Other terms & conditions of service generally as for appointment in the NHS.

Applicants should submit a curriculum vitae, naming three referees, to the Secretary, PHLS Board, 61, Colindale Avenue, London NW9 5EQ. Closing date: 12th October, 1979.

Researchers

Overseas Assignment

The Kuwait Institute for Scientific Research is a rapidly expanding institute for applied science and technology. We are currently seeking Researchers in the following disciplines to work in our Agriculture Department:

Researcher
Agriculture

In this position, you will investigate the best systems for protected agriculture under arid Kuwait conditions.

We require a PhD in Agricultural Engineering, or a related discipline, and a minimum of 4 years' experience in greenhouse system design, operation, productivity and evaluation.

Researcher
Poultry Nutrition

Working to investigate the variables affecting poultry nutrition and management in Kuwait, you will design nutritional management studies of various housing systems, using a minicomputer to obtain the lowest cost feed formulation and analysis of experimental data.

We require an M.SC. in Poultry Nutrition and Physiology and 5 or more years' research experience.

Kuwait Institute offers attractive salaries commensurate with qualifications and experience, furnished housing, liberal fringe benefits including round trip air tickets and free medical benefits.

Please airmail your complete resume by **October 24, 1979** to: **Mr. Habib Al-Sahhaf, Personnel Manager, Kuwait Institute for Scientific Research, P.O. Box 24885, Safat, Kuwait, State of Kuwait.**

Kuwait Institute for Scientific Research

W360(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

TEACHING TECHNICIANS

Grades AB and 3 required to assist the Superintending Technician in the preparation of histology sets and anatomical specimens to support teaching commitments in the Structural Biology Department. Applicants should have at least three years experience in a Biological laboratory. Further training to gain higher technical qualifications will be encouraged.

Grade 2b range £2,937 — £3,546. Grade 3 range £3,122 — £3,770. London allowance £275 p.a. Salaries and London allowance are under review.

Application forms and further particulars obtainable from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. For further details prospective candidates are invited to contact Mr J T Fish, Superintending Technician, 01-672 1255 Ext. 4615.

3267(A)

UNIVERSITY OF EXETER
DEPARTMENT OF GEOGRAPHY

TECHNICIAN
Grade 3

Applications are invited for the post of

GEOGRAPHY TECHNICIAN,

to work in the physical geography laboratories. The work involves mainly physical and some chemical analysis of soils and unconsolidated sediments.

Applicants should possess the Science Laboratory Technician's Part I Certificate or equivalent.

Salary scale £3,122 to £3,553 p.a. (becoming £3,313 to £3,770 p.a. at 1.4.80), (under review), with initial placement according to age, qualifications and experience.

Further particulars from Miss Doreen Watson, Northcote House, Queens Drive, Exeter, EX4 4QJ, to whom applications should be sent by 7 October 1979. Please quote reference No. 5130.

3230(A)

ELECTRON MICROSCOPY UNIT
Institute of Dermatology London E9

(University of London)

A post-doctoral research assistant is required to work on a project on cutaneous vascular responses to injury. The appointment will be for two years in the first instance with possibility of extension for a further year. Experience in E.M. techniques is essential. Starting salary £4,333 to £4,910 plus L.W. (£502) p.a.

Address applications, including full C.V. and names of two referees, or requests for further information, to Dr R A J Eady, Institute of Dermatology, St John's Hospital for Diseases of the Skin, Homerton Grove, London E9. Tel: 01-985 7061. Closing date is October 19th, 1979. 3268(A)

NEUROLOGICAL RESEARCHER
ASSOCIATE PROFESSOR LEVEL

The Virginia Mason Research Center is establishing a new Neuroscience Research Laboratory and would require the services of an experienced investigator in some area of neuroscience who could actively collaborate with clinicians in the Neurology and Neurosurgery Departments of the Mason Clinic and Virginia Mason Hospital. It is expected that this person will be capable of obtaining research grants nationally which, together with continued bequests, will allow the laboratory to grow, expand and develop. The VMRC is a $2,000,000 a year research center which houses the activities of 11 Senior Scientists, 20 Research Associates, and approximately 40 technicians and other professionally trained assistants.

Please send resumes to John C. Houck, PhD, Director, Virginia Mason Research Center, 1000 Seneca Street, Seattle, Washington 98101.

Virginia Mason Research Center is an Equal Opportunity Employer. W357(A)

THE ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen,
AB2 9SB

ANALYST
(Two year appointment)

An Analyst is required in the Applied Nutrition Department to undertake studies of the products arising from the large-scale fractionation of grass and other fodder crops. Candidates should have had training in chemical analytical techniques. Appointment will be for a period of 2 years.

Qualifications required: A degree in Chemistry or Biochemistry, or Higher National Certificate in Chemistry with relevant experience.

Appointment will be in the Scientific Officer or Higher Scientific Officer grade. Salary scale £3,289 to £5,085 (S.O.) or £4,727 to £6,211 according to qualifications and experience. On 1 January 1980 these scales will be increased to S.O. £3,591 to £5,486 and H.S.O. £5,097 to £6,737. At least 5 years' relevant post qualifying experience is normally requierd for H.S.O. grading.

Non-contributory superannuation scheme.

Further particulars are available. Applications, including the names and addresses of 2 referees, should be submitted to the Secretary of the Institute by 12 October 1979. 3223(A)

UNIVERSITY OF YORK MICROTEST

A young and energetic

RESEARCH SCIENTIST

is required by the above contract research group. The person appointed would be responsible for the day-to-day running of a large project concerned with determining the biological activity of diesel and petrol engine exhausts. Candidates should have a strong background in chemical fractionation procedures as well as an interest in short-term tests for carcinogens/mutagens. Starting salary up to £8,182 pa (under review).

Informal enquiries can be made by contacting Dr R.C. Garner, Cancer Research Unit (0904 411805). Four copies of applications and curricula vitae, naming three referees, should be sent by Monday 1 October 1979 to the Registrar, University of York, Heslington, York, YO1 5DD. Please quote reference numbr 11/6112.

3261(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited from biochemists or microbiologists for the post of

SRC POSTDOCTORAL RESEARCH ASSISTANT

to study the means by which soil bacteria obtain energy for growth from the oxidation of ammonium ions. Previous experience in microbiology is desirable. The appointment is for three years with a salary up to the rate of £4,910 per annum. (Scale effective from 1st October, 1979 and subject to further review).

Applictions, including a brief curriculum vitae and the names of two referees should be sent by 4th October 1979 to Dr P.M. Wood, Department o Biochemistry, Medical School, University of Bristol, University Walk, Bristo BS8 1TD. 3241(A)

UNIVERSITY OF OTAGO
Wellington Cancer and Medical Research Institute

Wellington Clinical School of Medicine Wellington, New Zealand

RESEARCH OFFICER
(Medical or Non-Medical)

Applications are invited from medical o science graduates for the position o Research Officer. Science graduates should possess a higher qualification such as PhD Medical graduates if not in possession of higher degree, will be encouraged to enro for such a qualification. Previous researc experience is not essential. The appointe will work in the field of atherogenesis an experimental pathology under the directorship of Professor W.E. Stehbens Commencing salary according t qualifications and experience within th scale NZ$14,673 to $25,729 (Medical) NZ$11,894 to $18,665 (Science graduates) Increases are pending.

Further particulars are available fror the Association of Commonwealt Universities (Appts), 36 Gordon Square London WC1H 0PF, from the Registrar c the University, P.O. Box 56, Dunedir New Zealand, or from the Director of th Institute (Professor W.E. Stehbens Wellington Clinical School, Wellingto Hospital, Wellington, New Zealand.

Applications close on *31 October 1979*

3233(A)

FACULTY, HUMAN BIOLOGY PROGRAM at Stanford University

in field of Public Policy Analysis. Half-time in Human Biology, a large undergraduate program integrating biological and behavioral sciences. Half-time in related Stanford department or school. Person with demonstrated research productivity, interested in undergraduate teaching, with organizational skills to help teach and coordinate a series of courses in health policy and environmental policy. Rank open. Begin September 1, 1980. Affirmative Action Employer. Application deadline October 15, 1979. Send vita to Albert H. Hastorf, Policy Search Committee, Human Biology, Stanford University, Stanford, CA 94305. W368(A)

UNIVERSITY OF ESSEX

FELLOW

in the

DEPARTMENT OF PHYSICS

(Laser-Photoconductivity in Semiconductors)

Applications are invited for a post of Fellow (starting salary up to £4,910 on Range 1A) tenable for 3 years, to carry out S.R.C. — funded experimental research into deep-level impurities in semiconductors in collaboration with Dr B.K. Ridley. Candidates should have a PhD or equivalent qualification. Experience of infrared lasers, semiconductors and low-temperature techniques would be useful but not essential.

Application should be made to Mrs D.A. Weatherall, Department of Physics, University of Essex, Wivenhoe Park, Colchester CO4 3SQ (tel. 0206 862286). 3270(A)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

Commonwealth Bureau of Horticulture and Plantation Crops East Malling Research Station, Nr. Maidstone, Kent

Duties: Preparing abstracts in English for the journal *Horticultural Abstracts*, which covers world scientific literature in this field, indexing and answering scientific enquiries.

Qualifications: A degree in horticulture, agriculture, botany, or related subject, plus a reading knowledge of at least one European language (German preferred) and the ability to write good English. Applicants must be able to render the content of scientific publications into concise, accurate and readable abstracts. It is expected that the successful candidate will wish to make a career in the field of scientific literature rather than research.

Salary: In the scale £2,839 to £5,448 (currently under review), plus a compensatory allowance (taxable but not superannuable) of 3.3 per cent of basic salary to offset personal contribution to superannuation scheme. Starting salary according to qualifications and experience. Promotion to higher scales on merit.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: 10 October 1979. 3222(A)

DIRECTOR HUMAN BIOLOGY PROGRAM at Stanford University.

Person with demonstrated research productivity, interested in undergraduate teaching, with organizational skills to administer large program integrating biological and behavioral sciences, with some policy emphasis. Half-time in Human Biology Program, half-time in a biologically related department in which applicant's experience merits tenure appointment as associate or full professor. Begin appointment September 1, 1980. Affirmative Action Employer. Application deadline October 15, 1979. Send vita to Sanford M. Dornsbusch, Human Biology, Stanford University, Stanford, CA 94305. W367(A)

UNIVERSITY OF EDINBURGH MEDICAL SCHOOL

DEPARTMENT OF MEDICINE

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOW

to work with CRC funded project on immune complexes in disease. Post tenable until September 1980 in the first instance. Salary scale £4,333 to £7,521 per annum according to qualifications.

For further particulars write to Dr W.J. Irvine, Endocrine Unit and Immunology Laboratories (Medicine), The Royal Infirmary, Edinburgh. Applications quoting the names of two referees should be addressed to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL not later than 11th October 1979. Please quote Reference 5060. 3255(A)

UNIVERSITY OF THE WITWATERSRAND, Johannesburg, South Africa

DEPARTMENT OF MICROBIOLOGY

LECTURER

Applications are invited from suitably qualified persons for appointment to the above post.

Applicants could have an interest in any aspect of Microbiology, although those with experience in bacteriological techniques as applied to ecology or plant pathology are encouraged to apply.

In addition to pursuing his/her own research, the incumbent will be required to participate in the teaching of the undergraduate and postgraduate courses given to students in the Faculty of Science, and to supervise research students.

Duties are to be assumed as soon as possible. The salary range is R8 100 to R13 100 per annum, the initial salary being determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities and a housing subsidy, if applicant is eligible. (£1 = R1.87 approx).

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above post are included in an information sheet obtainable from the London Representatve, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged by 15th October 1979. 3232(A)

We have the following vacancies in our Biochemistry Section:

Experimental Officer — Biochemist

A graduate biochemist to play a part in the discovery of new insecticides. An understanding of neurobiology would be desirable, but practical experience in insect biochemistry is not essential. However, candidates must have considerable experience of modern biochemical techniques.

The successful applicant will join a small team composed of one PhD and one graduate, responsible for initiating research in areas of insect biochemistry that could lead to a programme of chemical synthesis or produce *in vitro* methods for detecting active chemicals. Complementary work will be concerned with evaluating the mode of action of promising new insecticides and gaining an early understanding of the factors that may contribute to the development of resistance.

Experimental Officer — Physical Chemist/ Electrochemist

A Physical Chemist to work on the electrochemistry and reaction kinetics of exploratory organic compounds being synthesised as potential pesticides. A knowledge of chemistry at least up to HNC level is required, and experience of polarography or related techniques is desirable but not essential. The successful candidate will work closely with organic and bio-chemists, and will be in a small team headed by a PhD physical chemist. There will be scope for initiative in developing techniques and helping to design structures with the desired electrochemical properties.

Jealott's Hill is the chemical and biological research centre for the crop protection interests of ICI. It is situated in open country 30 miles west of London, between Bracknell and Maidenhead. We offer competitive salaries and fringe benefits including membership of the ICI Profit Sharing and Pension Fund. Coaches run between Jealott's Hill, Bracknell and Maidenhead.

If you are interested in this vacancy please write or telephone for an application to:

Mr S R Stephenson
ICI Plant Protection Division
Jealott's Hill Research Station
Bracknell, Berks. *Ref no 79/Biochem*

ICI Plant Protection Division

3231(A)

POSTDOCTORAL FELLOW

Post available immediately for PDF to work on gas/solid reactions. Stipend and benefits up to maximum allowable by NSERC regulations.

Please forward applications with names of two referees to:

Dr R.A. Ross
Department of Chemistry
Lakehead University
Thunder Bay
Ontario
Canada P7B 5E1

W365(A)

Lakehead University

UNIVERSITY OF SHEFFIELD

A vacancy exists in the Department of Medical Microbiology at the Medical School, Hallamshire Hospital for a

MEDICAL LABORATORY SCIENTIFIC OFFICER

to take part in a 3 year research programme concerned mainly with immunological technique as applied to aspects of cancer research and other clinical problems. The post affords an opportunity for a suitable candidate to prepare a thesis for a higher qualification. Enquiries regarding the post to Dr A. Clark, telephone number (0742) 26484, ext. 2968/2027. Salary on N.H.S. scale for M.L.S.O.'s £3,768 to £5,391 p.a. (under review). Please write, giving the names of two referees to the Administrative Officer (Personnel), Ref. S 1374/N, The University, Sheffield S10 2TN. 3257(A)

Ministry of Agriculture, Fisheries and Food

Scientist

to help co-ordinate R & D

. . . to join the Chief Scientist's Group which is responsible for the planning of the research and development programme for agriculture, fisheries and food.

The Scientist appointed will help to liaise with food manufacturers and contractors and review annually the commissioning and financing of R & D activities in the food industry. The work includes classifying current food R & D activity, drafting reports and papers, reviewing technical and scientific literature and interpreting the data.

No laboratory work is involved but some visits to R & D establishments may be required.

Candidates (normally aged under 27) should have a good honours degree or equivalent in a suitable scientific subject.

Appointment will be as Scientific Officer £4,065 to £5,865 (to become £4,370 to £6,265 from 1.1.80). Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 15th October, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote reference SB/43/AE.* 3226(A)

Science Group
CIVIL SERVICE

VIROLOGIST
Assistant Professor

Two-year appointment with the possibility of tenure track. Salary commensurate with experience. To teach 2 half year lecture courses in Virology at the third and fourth year levels plus 1 half year Virology techniques laboratory. The candidate should have a PhD, some post-doctoral experience and be capable of developing a research program in Virology.

Excellent research facilities including Tissue Culture, Radioisotope and Biohazard containment laboratories are available.

The position is to start January 1, 1980, or as soon as a suitable candidate can be found.

Curriculum Vitae with names of 3 referees should be sent not later than December 15, 1979 to:

Chairman,
Department of Biology,
University of New Brunswick,
Fredericton, N.B.,
Canada E3B 5A3

W371(A)

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENT OF AGRICULTURAL AND FOOD CHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited from plant physiologists for an ARC sponsored research project investigating the genetic control of photorespiration in ryegrass and other crop plants. The project will be under the direction of Dr M.K. Garrett and aims to investigate the occurrence of RuBP carboxylase/oxygenase variants and interpret their physiological significance. Experience in enzymology and whole plant physiology is essential. Appointment is for 3 years with a starting salary in the range £4,333 to £4,910 with USS. Applicants should submit a full curriculum vitae including the names and addresses of two referees to the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland. Closing date: 26th October 1979. 3219(A)

QUEEN ELIZABETH HOSPITAL FOR CHILDREN
DEPARTMENT OF CYTOGENETICS

Hackney Road, London E2 8PS

BASIC GRADE CYTOGENETICIST

Applications are invited from honours graduates whose biological science courses contained units in genetics/cytogenetics, cell biology and biochemistry. Some knowledge of data processing would be an advantage.

Employment will be on the Basic Grade PTA scale for graduates in the National Health Service in accordance with Whitley Council Regulations. Current starting salary £4,035 p.a. + £354 London Weighting p.a.

Apply by letter to the Principal Cytogeneticist enclosing a curriculum vitae and the name of two referees.

Closing date 4th October, 1979. 3214(A)

HARVARD UNIVERSITY

PROFESSOR
HEALTH POLICY ANALYSIS
DEPARTMENT OF BIOSTATISTICS

The position will require an extensive background, and demonstrated research productivity in the application of quantitative analytical techniques to programmatic evaluation and of decision analytic concepts to policy issues in the health sector. The investigative activities of the faculty member will involve collaborative research with physicians and other members of the health-related professions as well as the teaching of statistical and other quantitative analytic methods to graduate students, and supervision of doctoral candidates.

Send application and vitae to Frederick Mosteller, Chairman, Department of Biostatistics, 7th Floor, School of Public Health, Harvard university, 677 Huntington Avenue, Boston, MA 02115.

Harvard University is an Equal Opportunity/Affirmative Action Employer. W374(A)

AGRICULTURAL RESEARCH COUNCIL
Food Research Institute
SCIENTIFIC SERVICES AND DEVELOPMENT DIVISION

CHEMIST

A Scientific Officer is required to join, on a temporary basis, the Chromatography Development Group which is part of the Scientific Services and Development Division.

The appointment relates to a research contract ending in October 1980, which has as its objective the estimation in poultry waste of residues of specified veterinary products.

Published gas chromatographic methods will be worked up but some method development will be necessary.

A pass degree or HNC in chemistry, together with a knowledge and practical experience of high performance liquid chromatography and/or gas chromatography, are required.

Salary: From 1st August 1979: on a scale £3,289 to £5,085. From 1st January 1980: on a scale £3,591 to £5,486.

Five-day working week and flexible working hours scheme operated. Transport facility available mornings and evenings.

Further particulars and application forms from: The Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting Ref. No 79/9. Closing date 4th October, 1979. 3265(A)

MRC PNEUMOCONIOSIS UNIT
Llandough Hospital, Penarth, South Glam. CF6 1XW.

POST-DOCTORAL RESEARCH SCIENTIST

Applications are invited for a three year post-doctoral appointment at the above Unit. The successful applicant will join the cellular immunology group, studying the effects of dust exposure on human populations and on the cells of the immune system of animals. He/she will be involved in the development of techniques related to human monocytes and rat macrophages associated with tumours produced by dusts.

The salary will depend on experience and will be within the range £4,232 to £6,627.

For further details and an application form write to the Assistant Administrative Officer. 3259(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
BONE AND JOINT RESEARCH UNIT

RESEARCH ASSISTANT

Applications are invited from graduates with a good honours degree in physiology, biophysics or similar qualifications, for the appointment of a Research Assistant within a team studying the physical chemistry of cartilaginous tissues. The successful candidate will be required to investigate the effect of mechanical loading on the permeability and structure of the tissue matrix.

This appointment is for a period of three years and is financed by a grant from The Wellcome Trust. Initial salary, inclusive of London Allowance, in the region of £5,000 per annum (subject to review as from 1st October 1979).

Further enquiries to Dr Maroudas, Tel. 01-247-5454 Ext. 421. Applications to The Secretary, The London Hospital Medical College, Turner Street, London E1 2AD. 3260(A)

British Nutrition Foundation

The BNF combines the expertise of leading medical, academic, governmental and industrial experts in its educational and research activities.

There are two vacancies for persons of high ability:

SENIOR SCIENTIFIC OFFICER (SSO)
SCIENTIFIC INFORMATION OFFICER (SIO)

The SSO will have a good honours degree and several years relevant post-graduate experience. The varied work will include 'in depth' studies and the preparation of reports for publication.

The SIO will have a good honours degree or other relevant qualification and experience, and must be capable of explaining matters relating to food, nutrition and health in simple terms, by written and spoken word to health and education professionals and to lay persons.

Applications should reach the Secretary, British Nutrition Foundation, 15 Belgrave Square, London SW1, before Monday 1 October 1979.

3264(A)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

POSTGRADUATE/POST-DOCTORAL RESEARCH ASSISTANT IN NEUROPHARMACOLOGY

Applications are invited for this post, funded by The Wellcome Trust, to work with Dr C. A. Marsden on the effects of long-term antidepressant drug administration on neurotransmitter systems in the rat using *in vivo* electrochemical techniques. Previous experience with implanting eletrodes in the CNS would be an advantage. The appointment is for three years commencing October 1979 or as soon as possible thereafter. Initial salary in the range of £3,775 to £4,333.

Applicants should send their curriculum vitae and names of two academic referees to Professor P.H. Fentem, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH as soon as possible.

3234(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of

RESEARCH FELLOW

in the above Department to work with Dr D.A. Harris on a project supported by the S.R.C. on enzymology of ATP synthesis by mitochondria and/or Chloroplasts. The work will involve studies of chemical modification of isolated and membrane proteins, and rapid reaction kinetics. Candidates should already possess, or expect to be awarded, a PhD degree, within the next few months. The appointment will be made for a fixed period of three years.

Starting salary in the range £4,333 to £4,910 on the 1A scale for Research and Analogous Staff (£4,333 to £7,521) (under review).

Informal enquiries about the post will be welcomed by Dr D.A. Harris (Telephone (0532) 36171 ext. 86).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/24/D. Closing date for applications 12 October 1979.

3220(A)

USER SUPPORT PROGRAMMER

The Daresbury Laboratory, located in the Cheshire countryside, is developing major national facilities for research into atomic, molecular, solid state and nuclear physics. Exploitation of these facilities requires first-class computing support. Computers at the Laboratory include a CRAY-1, an IBM 370/165, GEC 4070's, PDP-11's and Interdatas.

The vacancy is in the user support group which is responsible for producing general support for users of the Daresbury computer system. An important facet of this work is the exploitation of the powerful CRAY-1 computer which is to be used for extremely large scientific calculations. Computing experience, especially scientific computation, is required although training will be provided.

Appointment will be made at Higher Scientific Officer grade. Applicants, of either sex, should possess a good honours degree in a relevant subject, plus at least 2 years post graduate experience.

Salary will be assessed according to experience on the following scale:
£4,727 to £6,211 which will increase from 1st January 1980 as follows:
£5,097 to £6,737

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

Closing date 19th October 1979.

Please write, or telephone Warrington 65000 Ext. 467 for an application form quoting reference No. DL/703 to

The Personnel Officer
DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

3269(A)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

RESEARCH ASSISTANT

Applications are invited for a Research Assistantship for three years funded by the Nuffield Foundation to work on the cell-free synthesis of myelin proteins. Salary on the IB scale. Applicants should be of graduate standard with a qualification in Biology, Physiology or Molecular Biology.

Further information is available from Dr S J S Hardy or Dr M G Rumsby at the address below. Three copies of applications and curricula vitae, naming two referees should be sent as soon as possible to the Registrar, University of York, Heslington, York YO1 5DD. Please quote reference number 11/7082.

3242(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the

CHAIR IN MINERAL EXPLOITATION.

The salary will be within the Professorial range. Duties to commence on 1st January 1980, or as soon as possible thereafter.

Applications (two copies), together with the names and addresses of three referees should be forwarded, no later than the 31st October, 1979, to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL from whom further particulars may be obtained. Reference 1897.

3254(A)

DEPARTMENT OF CHILD HEALTH

UNIVERSITY OF MANCHESTER

RESEARCH FELLOW IN ANATOMY

Postdoctoral Research Fellow required in multidisciplinary research team to organise new work in quantitative histology, mainly but not exclusively in the brain.

Enquiries with full curriculum vitae to Professor John Dobbing, The Medical School, Oxford Road, Manchester M13 9PT

3197(A)

UMIST

DEMONSTRATOR IN MICROSCOPY AND PHYSIOLOGY

Applicants should have a recent PhD or MSc. The post includes both research and teaching. Research work will be in collaboration with Dr N M Tyrer into synaptic structure and function in the insect CNS, involving electron microscopy of cobalt filled neurones and histochemical identification of synaptic transmitters. Teaching duties include supervision of third year EM projects and demonstrating in an elementary physiology course.

Salary is on the scale £3,775 to £5,488 per annum.

Letters of application, quoting reference B10/179, including a curriculum vitae and the names of two referees, should be addressed to Dr N M Tyrer, Department of Biochemistry, UMIST, PO Box 88, Manchester, M60 1QD.

3249(A)

X-RAY CRYSTALLOGRAPHER Research Associate to conduct x-ray diffraction studies on liquid crystals in well equipped laboratory. Required PhD or equivalent experience. Salary: $11-15,000 annually, depending on qualifications. Reply to Dr Leonid V Azaroff, Director, Institute of Materials Science, University of Connecticut, Storrs, CT 06268 before October 22, 1979. An Equal Opportunity Employer.

XW328(A)

UNIVERSITY OF NATAL

DEPARTMENT OF GEOLOGY

PIETERMARITZBURG

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin, for appointment to the post of

LECTURER

The salary will be in the range:

R8 100 — R13 200 per annum

The commencing salary will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions, and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, P.O. Box 375, Pietermaritzburg, 3200, South Africa, with whom applications, on the prescribed form, must be lodged not later than 9 November 1979, *quoting reference PMB 62/79.*

W363(A)

Upjohn *medicine . . . designed for health . . . produced with care*

GRADUATE

STRERILE PHARMACEUTICAL PRODUCTION

Upjohn Limited is the wholly owned subsidiary of The Upjohn Company, USA, and is a leading pharmaceutical house based in West Sussex. A vacancy has arisen for a graduate to join our production team in the Sterile Products Manufacturing Unit, formulating and aseptically packaging a variety of sterile ethical human and veterinary products.

The successful applicant will eventually be responsible for either the manufacturing and preparation operations, or the aseptic filling operations on a rotational basis. This will involve supervising and controlling the work of ten to fifteen operatives at any one time.

Applications are invited from graduates in Microbiology, or who are M.I.Biol. qualified, and who have up to two years experience in the pharmaceutical or similar industry.

In return we can offer a competitive compensation package which includes a 36 ¼ hour working week, contributory pension scheme, free life assurance and disability plans and relocation assistance where appropriate.

For further information and an application form candidates should apply to:-

The Personnel Officer,
Upjohn Limited,
Fleming Way,
Crawley,
West Sussex RH10 2NJ
Telephone: Crawley 31133.

INSTITUTE OF CANCER RESEARCH: PHYSICIST required for interesting post in Radiological Physics at the Royal Marsden Hospital, Fulham Road, London, SW3. The person appointed will be one of a team covering radiotherapy, diagnostic radiology, and nuclear medicine. He or she will have special responsibilities for Radiation Protection and for new techniques in diagnostic radiology. Some postgraduate experience in this or a related field is desirable but new graduates with good degrees may apply. Appointment at an appropriate point on Grade II of MRC scales £4,261 p.a. to £6,627 p.a. plus London Allowance of £502 p.a. Apply in duplicate giving full CV and names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 300/G/15. 3228(A)

FACULTY POSITIONS.

THE DEPARTMENT OF CHEMISTRY

SYRACUSE UNIVERSITY

invites applications from outstanding candidates in all fields of chemistry. During the coming year we expect to make two or three appointments, probably at the level of assistant professor, tenure track, with possibility of appointment at chemistry, organometallic chemistry, and analytical chemistry.

Applicants should send a complete curriculum vitae, list of publications, summary of teaching experience, and a statement of research plans, and should arrange for at least three letters of recommendation to be forwarded to support the application.

Nominations and applications should be mailed by November 1 to Professor B.R. Ware, Chairman, Department of Chemistry, Syracuse University, Syracuse, New York 13210. Syracuse University is an Equal Opportunity/Affirmative Action employer. W369(A)

UNIVERSITY OF BRISTOL

SCHOOL OF CHEMISTRY

GRADUATE RESEARCH ASSISTANT

Applications are invited from plant biochemists or plant biologists for this post to undertake research into the identification, photo-control of levels, and metabolism of gibberellins in plant leaves and etioplasts. The post which is funded by ARC is tenable for three years at a salary of £3,775 to £4,333 (Scale effective from 1st October, 1979 and subject to further review). The successful candidate will be encouraged to register for a higher degree.

Applicants should send a curriculum vitae and names of referees as soon as possible, to Professor J. MacMillan, School of Chemistry, The University, Bristol BS8 1TS. 3164(A)

KING'S COLLEGE LONDON

RESEARCH TECHNICIAN

Applications are invited for this post to assist with a project investigating the properties of pyruvate carboxylase in wild-types and mutant strains of Aspergillus nidulans. A knowledge of enzymology, microbiology and associated biochemical techniques is desirable. Minimum qualifications, ONC/HNC or equivalent, preferably with several years relevant experience. This post is financed by the SRC for 1 year with the possibility of renewal for a further 1 year. Salary on scale £3,646 pa to £4,077 pa inclusive (under review). Five weeks annual holiday.

Interest-free loans for annual rail season tickets.

Apply in writing with full details, naming two referees to: The Head Clerk (Ref: 221707/N), King's College London, Strand, WC2R 2LS. 3253(A)

LEICESTER POLYTECHNIC

SCHOOL OF CHEMISTRY

SENIOR TECHNICIAN IN MASS SPECTROMETRY

Applications are invited from graduates in a relevant science for this post which will involve operating a new mass spectrometer system comprising a PYE 204 Chromatograph, a VG 16 F Mass Spectrometer and a VG Display Digispec Data System.

In addition to providing a service for the teaching and post graduate work of the Science Faculty there will be novel and interesting duties in connection with the provision of a service to industrial users on a commercial basis; this will involve extensive liaison with industrial laboratories.

Applicants should have at least three years experience as mass spectroscopists and preferably be competent in the maintenance of the system.

Salary: £5,220 to £5,547 per annum.

Application forms available from Staffing Officer, Leicester Polytechnic, PO Box 143, Leicester LE1 9BH. Tel (0533) 551551 ext 2303. 3238(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

UNIVERSITY OF EDINBURGH:

THE EDINBURGH SCHOOL OF AGRICULTURE

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from plant pathologists, soil microbiologists or those in related disciplines, for a 3 year post-doctoral position financed by the ARC from 1st October 1979. The study involves early stages of parasitism by cereal root- and foot-rot fungi; it is hoped to determine if natural senescence of host tissues enhances infection and if biological control operates by competition for senescing tissues. This has important fundamental and practical implications.

Starting salary £4,522, rising to £4,865 in third year.

Applications by *curriculum vitae*, with names of two referees, to Dr J.W. Deacon, Microbiology Department, School of Agriculture, West Mains Road, Edinburgh, EH9 3JG, from whom further particulars can be obtained. 3212(A)

INSTITUTE OF CANCER RESEARCH: TECHNICIAN required for Treatment Planning Group, Physics Department, Royal Marsden Hospital, Fulham Road. Applicants should have a degree in Physics or appropriate experience in radiological physics. The appointed person will be trained to prepare treatment plans using a PDP8E computer and will be closely involved with radiotherapy techniques and measurements. Treatment machines include three Cobalt units, at 10 Mv Linear Accelerator and orthovoltage X-ray equipment. Appointment will be at the appropriate point on the Technician scale £3,261 p.a. to £4,680 p.a. (scales under review) plus London Allowance of £354 p.a. Apply in duplicate giving the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/85. 3227(A)

ASSISTANT PROFESSOR OF MICROBIOLOGY. The Department of Microbiology and Immunology, Washington University School of Medicine invites applications from highly qualified individuals for an appointment as Assistant Professor. Applicants should have PhD or MD degrees, 2-5 years of post-doctoral research experience and a commitment to medical and graduate student teaching. Teaching competence should be in pathogenic microbiology; research interests should be in microbiology. Send curriculum vitae, brief description of research plans and names of three referees to Dr Joseph M Davie, Department of Microbiology and Immunology, Washington University School of Medicine, St Louis MO 63110 by November 1, 1979. Equal Opportunity and Affirmative Action Employer M/F/H. W339(A)

MEDICAL RESEARCH COUNCIL

LABORATORY OF MOLECULAR BIOLOGY

POST-DOCTORAL RESEARCH SCIENTIST

is required for a short-term three-year appointment.

The person appointed will be required to work at the Institute of Animal Physiology at Babraham, Cambridge, and will work on the subject of complement activation and its application to clinical problems.

Salary on scale starting from £5,048 (pay award pending).

Applications, with *c. v.* and names of two referees, should be sent to the Administrative Secretary, MRC Laboratory of Molecular Biology, The Medical School, Hills Road, Cambridge CB2 2QH, to be received not later than 1st November, 1979. 3277(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

tenable for three years and three months from 1 November 1979 to work with Professor B.H. Bransden in the Department of Physics on the Theory of Atomic Charge-Exchange Reaction, with special reference to Heavy Ion Fusion.

Initial salary in the range £4,333 to £7,227 on National Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 19 October 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE from whom further particulars may be obtained. 3276(A)

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE AND DENTISTRY

RESEARCH FELLOW GRADE Ia or II

equired to work in the Department of edicine (Clinical Oncology). The post volves studies on steroid and peptide ormone reseptors in Breast Cancer and ould be required to direct the research ork of a small Group of Fellows and echnicians and be responsible for onitoring routine steroide Hormone ssays.

Salary will be according to age and perience on the scale Research Fellow IA 4,333 to £7,521) or II (£6,932 to £8,992). ith super annuation benefits.

Further particulars may be obtained om professor R. Hoffenberg. epartment of Medicine Queen Elizabeth ospital Birmingham B152 TH.

Applications (Three Copies) should be nt to the assistant registrar, the Medical hool Birmingham B15 2TJ by 12th ctober 1979 please quote Ref.RF/Med 9. 3275(A)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMICAL ENGINEERING AND FUEL TECHNOLOGY

pplications are invited from men and omen for the post of

RESEARCH ASSISTANT

work with Professor J.A. Barnard on an R.C.-funded project entitled High emperature Pyrolysis of Hydrocarbons. he work will involve using a single-pulse ock tube to study the pyrolysis of ydrocarbons typical of those present in aphtha with the objective of establishing a odel of naphtha-cracking reactions at mperatures above those currently nployed in industry. Experience in gas netics and computing an advantage. itial salary up to £4,910 + U.S.S. Tenue years.

Applications to Professor J.A. Barnard, epartment of Chemical Engineering and uel Technology, the University, Sheffield 1 3JD, enclosing a curriculum vitae and ames of two referees. Quote ref: R363/G. 3237(A)

THE UNIVERSITY OF THE SOUTH PACIFIC — Fiji

Applications are invited for the post of

UNIVERSITY FELLOW (Post 79/84)

in the newly established Atoll Research Unit (Aru) of the Institute of Marine Resources (IMR). The Atoll Research Unit is to be located on Tarawa, in Kiribati. The appointee, who should be a marine biologist will be intially required to develop and carry out where practicable the applied research, advisory and educational programmes of the Unit, in consultation with the director of IMR. The most immediate project to be undertaken by the appointee is a survey of Tarawa lagoon and subsequent monitoring of any existing pollution indices. He/She will be appointed at lecturer or senior lecturer level. Housing and some laboratory facilities are available. An appropriate vehicle for transportation on Tarawa will be provided. Salary scales: Senior Lecturer — F$11960 to F$14135 pa, Lecturer — F$8175 to F$11563 pa (£1 sterling = F$1.83). The British Government may supplement salaries in range £3,504 to £4,662 pa (sterling) for married appointee and £1,788 to £2,664 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide children education allowances and holiday visit passages. Family passages; baggage allowance; 15% gratuity; superannuation scheme; appointment allowance; partly furnished accommodation at maximum rental of 12½% of salary (under review); 3 year contract.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University of the South Pacific, PO Box 1168, Suva, Fiji by 24 October 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 3278(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF BIOPHYSICS

TECHNICIAN Grade 3

preferably with experience in tissue culture or histology to assist in nerve-muscle research. Appointment for one year with possibility of extension. Salary £3,205 + £524 London Weighting.

Applications to Professor R. Miledi, Dept. of Biophysics, University College London, Gower St, London WC1E 6BT. 3266(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Department of Pharmacology RESEARCH FELLOW

The successful applicant will be expected to pursue research under the general direction of Professor D.R. Curtis into synaptic mechanisms within the mammalian central nervous system at a cellular level, and to be familiar with the relevant anatomical, biophysical, and pharmacological techniques. Further information may be obtained from Professor Curtis, in the University. Closing date 15 October, 1979.

RESEARCH SCHOOL OF PHYSICAL SCIENCES

POSTDOCTORAL/RESEARCH FELLOWS:

In 1980 the Research School proposes to appoint up to six (School) Postdoctoral/Research Fellows, in addition to appointments to such positions falling vacant in specific departments.

The School currently consists of six departments (Applied Mathematics, Engineering Physics, Mathematics, Nuclear Physics, Solid State Physics and Theoretical Physics), three units (Diffusion Research, Electron and Ion Diffusion and Ultraviolet Physics), a Plasma Research Laboratory and the Mount Stromlo and Siding Spring Observatories; both the latter have the status of departments.

Nomenclature of appointment and salary will be determined in accordance with qualifications and experience. Closing date: 31 October, 1979.

DEPARTMENT OF THEORETICAL PHYSICS

POSTDOCTORAL FELLOW, RESEARCH FELLOW OR SENIOR RESEARCH FELLOW:

The Department would prefer to make the appointment in the research area of statistical mechanics, but applications from theoretical physicists with research interests in other areas will be considered. The Department's main current interests are in fundamental aspects of statistical mechanics, solid state physics, plasma physics, nuclear physics, elementary-particle physics and field theory. Applications would be welcomed from persons on leave from their institutions for shorter periods (but for at least two years for institutions outside Australia). Closing date: 30 November, 1979.

FACULTY OF ARTS

DEPARTMENT OF PREHISTORY AND ANTHROPOLOGY

Applications are invited for appointment to two posts in the Department of Prehistory and Anthropology. The headship of the Department alternates between Professor Anthony Forge and Professor D J Mulvaney.

LECTURER IN ANTHROPOLOGY:

Applicants should have a good scholarly record in research and teaching in Social or Cultural Anthropology. Experience in the field of Melanesia may be an advantage.

LECTURER IN BIOLOGICAL ANTHROPOLOGY:

Applicants should have research interests and teaching experience in biological anthropology which fit into the needs of the Department which has established streams of Prehistory and Social Anthropology and a developing program in Biological Anthropology. The successful applicant will have to teach in fields which aid the integration of these subjects, certainly including human adaptability, nutrition and growth, epidemiology, human variation and genetics.

There is already one Physical Anthropologist, Dr C.P. Groves, in the Department but other staff members of both streams are concerned with aspects of Biological Anthropology. Closing date 15 November, 1979.

Salaries: Salaries will be in accordance with qualifications and experience within the ranges: Senior Research Fellow $A22,755-27,143; Research Fellow $A16,291-21,265; Lecturer $A16,291-21,401; Postdoctoral Fellow — a fixed point within the range $A16,291-20,768. Present exchange rate $A1 = 50p. (A salary loading of up to $A2,500 per annum may be paid to an applicant for the position in Pharmacology holding appropriate medical qualifications).

Term of Appointment: Research Fellow/Senior Research Fellow: normally three to five years with the possibility of extension to a maximum of eight years. Research Fellow in Pharmacology — two years with possible extension to five years. Postdoctoral Fellow: one to two years, although persons from overseas are not normally appointed for less than two years. Lecturer: three years in the first instance with the possibility of reappointment after review to age 65.

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should first obtain the further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 3213(A)

MARINE COORDINATOR

Person with the following qualifications: M.S. degree and/or five years experience in oceanography or a related field; must be thoroughly familiar with equipment, logistical problems and procedures used in marine sciences; must be able to do budgetary accounting and to supervise the work of a supporting staff. Salary range in $16-18,000 per annum. Application deadline is October 31, 1979.

Apply with résumé to:

Dr. William M. Sackett, Chairman
University of South Florida
Department of Marine Science
830 First Street South
St Petersburg, Florida 33701

W373(A)

TECHNICIAN/ RESEARCH OFFICER

required to assist in the Immunopathology Laboratory at our Mill Hill Laboratories, London, N.W.7. with investigations into relationships between autoimmunity malignancy and virus infection in mice.

HNC/Degree with experience in tissue culture techniques essential, particularly for the detection and isolation of RNA tumour viruses. Knowledge of basic immunology and embryology an advantage. Salary range £4,174 to £5,950.

For further information and application form, write or telephone to Miss S.M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2. on 242 0200 ext. 305, quoting reference 405/79. 3274(A)

THE UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE

Pittsburgh, Pennsylvania

DEPARTMENT OF BIOCHEMISTRY CHAIRMAN

Applications and nominations are invited for the position of Chairman and William S. McEllroy Professor of the Department of Biochemistry. The candidates should be recognized scholars and investigators with demonstrated commitment to medical and graduate education.

Curriculum vitae and bibliography may be submitted to Professor Winton Tong, Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, Pennsylvania 15261.

An Equal Opportunity/Affirmative Action Employer. W362(A)

THE UNIVERSITY OF CALGARY

ARCTIC INSTITUTE OF NORTH AMERICA

EXECUTIVE DIRECTOR

The Arctic Institute of North America, The University of Calgary, is seeking applications for the position of Executive Director. The successful applicant is expected to hold a Doctorate degree from a recognized university, or equivalent qualifications; to have an established background in Arctic and Northern studies; university teaching experience, or an interest in teaching; and managerial ability. The Executive Director is a senior academic appointment liaising with the university administration through the Office of the Vice-President (Academic). Salary and benefits will depend on qualifications and experience.

Further details may be obtained from

Dr. K. E. Cooper
Associate Vice-President (Academic)
The University of Calgary
Calgary, Alberta T2N 1N4
Canada

to whom the letters of application together with a detailed curriculum vitae should be sent.

W359(A)

GUY'S HOSPITAL MEDICAL SCHOOL

GRADUATE PHYSICIST

required as Research Assistant participating in a radiology research project supported by the D.H.S.S., for the further development of panoramic (oral) techniques, with special reference to dosimetry and the application of xeroradiography.

This appointment provides an excellent training which would be valuable to a scientist wishing to enter an important growth area of radiology.

The appointment is until 30th April 1982 and the salary scale is £3,802 to £5,488 plus £740 London Allowance and superannuation.

Apply in writing, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref OM2. 3243(A)

UNIVERSITY OF CALIFORNIA
Berkeley

DEPARTMENT OF PHYSICS

RECENT PhDs

wanted for two positions in rare gas mass spectrometry opening between January 1 and April 1, 1980. Salary range $16,308 to $19,700 for one to two years. Experimental background required in research on planetary materials or geochemistry.

Appointees will have much independence in research on trapped rare gases in meteorites, rare gas dating of meteorites, and/or terrestrial rare gases.

Send by October 15, 1979, resume, statement of interests, and 2 or 3 references to Prof. J.H. Reynolds, Dept. of Physics, University of California, Berkeley, CA 94720. The University of California is an Equal Opportunity/Affirmative Action Employer. W372(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF ORTHOPAEDIC AND ACCIDENT SURGERY

TECHNICIAN

for research project concerning the biological approach to replacement of arthritic joints. Facilities are available for cartilage and bone cell culture. Previous experience of immunological techniques desirable, but training given.

Candidates must possess HNC or appropriate equivalent qualification and have had several years laboratory experience.

Salary within a range £3,700 to £4,320 p.a., according to qualifications and experience.

Application forms available from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/777/N. 3215(A)

UNIVERSITY OF MANCHESTER

RESEARCH FELLOW IN RHEUMATOLOGY

Applications invited for this three-year appointment to work in the field of immunology, biochemistry and tissue culture work. The project involves basic research into the pathogenesis of rheumatoid arthritis and similar diseases. The work would be suitable for presentation as a PhD thesis, if not already held. The laboratory facilities and support are excellent.

The appointment would be available from September 15th, 1979. Salary range p.a. up to £5,400 (under review) according to qualifications. Further information from Dr P.J.L. Holt, University of Manchester Medical School, Department of Rheumatology, Manchester M13 9PT (Tel. 061-273 8241, Ext. 102). 3229(A)

FELLOWSHIPS

UNIVERSITY COLLEGE CORK
IRELAND

CORK HARBOUR MARINE BIOLOGY RESEARCH PROJECT
(N.B.S.T.)
2 Posts

A. POST-DOCTORAL RESEARCH FELLOWSHIP

A Zoologist is required for studies on the benthic ecology of Cork Harbour. The appointment will be for one year.

Applicants should have a PhD degree or equivalent experience.

Salary Scale: £4,182 to £4,845.

B. RESEARCH ASSISTANT

A Biologist is required to assist with Botanical and Zoological studies of Cork Harbour. The appointment will be for one year.

Applicants should have an honours degree in either Botany or Zoology or both.

Salary Scale: £2,919 to £3,941 per annum depending on qualifications.

Diving experience would be an advantage for either of the above positions but is not essential.

Applications for the above posts with curriculum vitae together with the names and addresses of 2 referees should be sent by **1st October, 1979** to Project Director, Dr. John Cullinane, Botany Department, University College, Cork. 3236(E)

RESEARCH FELLOWSHIP

A post-doctoral cytogeneticist or molecular biologist, with experience in human karyotyping, is required to participate in a project on the analysis of chromosomes from human solid tumours.

The appointment is for three years. Salary with entry according to qualifications and experience within range £5,990 to £7,434 inc. L.A. For further information telephone Dr E. Solomon 242 0200 extension 426.

Applications with curriculum vitae and names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2., quoting reference 407/79. 3273(E)

THE HARTLEY FELLOWSHIPS of the UNIVERSITY OF SOUTHAMPTON

Applications are invited for three Fellowships normally tenable from 1 October 1980, for up to two years research, in any field for which facilities are available within the Faculties of Arts, Science, Engineering & Applied Science, Social Sciences, Law, Education, Medicine and Mathematical Studies.

Fellows will normally be appointed from persons of high promise whose records show evidence of capacity for original research, and who have up to five years post-doctoral experience or equivalent research record.

Salary will be related to age and experience and be within nationally agreed ranges for research staff in universities. (No provision for travel or removal expenses).

The closing date for applications for the 1980 competition is 1 November 1979.

Details and application forms from Mr E.D. Gordon, The University, Southampton SO9 5NH.

THE LADY DAVIS FELLOWSHIP TRUST
PO BOX 1255, JERUSALEM, ISRAEL

FELLOWSHIPS FOR STUDY AND/OR RESEARCH AT GRADUATE OR POST-DOCTORAL LEVELS AND VISITING PROFESSORSHIPS

in 1980 — 81

at the Hebrew University of Jerusalem and at the Technion — Israel Institute of Technology, Haifa

GRADUATE AND POST-DOCTORAL FELLOWSHIPS

Eligibility: Lady David Fellows will be selected on the basis of demonstrated excellence in their studies, promise of distinction in their chosen fields of specialization and qualities of mind, intellect and character.

Post-doctoral candidates shall have completed their doctoral dissertation before arrival in Israel.

The Graduate and Post-doctoral Fellowships are tenable for a period of one year. They may be renewed for a second year and in special circumstances extended to a third year.

The grant is intended to defray the cost of the Fellow's travel and tuition fees and to meet reasonable living expenses.

Application: Graduate candidates may apply during their senior academic year or after they have undertaken study in a graduate school. Post-doctoral candidates may apply at an early stage of their professional career (not later than 3 years after completion of their doctoral dissertation).

Graduate and Post-doctoral candidates (including Israelis abroad) may obtain application forms from the Lady Davis Fellowship Trust at the above address, after they indicate the category of Fellowship for which they are eligible.

Completed applications must reach the office of the Trust not later than January 1, 1980.

VISITING PROFESSORSHIPS

These Fellowships are intended for candidates with the rank of Full or Associate Professor at their own institution. They are tenable for periods from one trimester (or semester) to a year.

Application: Forms may be obtained from the Lady Davis Fellowship Trust at the above address. Completed application forms for the Hebrew University must reach the office of the Trust by November 30, 1979. Those for the Technion — by December 31, 1979. 3263(E)

SEMINARS and SYMPOSIA

EORTC SYMPOSIUM

Immunopharmacologic Effects of Radiotherapy

Montpellier, France
13th 14th and 15th March 1980

The program will include invited and proferred papers.

The meeting is designed to promote discussions among following topics:

Effects of ionizing radiation on the immune response: clinical and experimental aspects.

Immediate, secondary and long term incidences of the radiotherapy on the immune response and on the host-tumor relationship in cancer patients.

— Correction or modulation of the changes induced by radiotherapy.

— Therapeutical associations: radiotherapy — immunotherapy; radiotherapy — chemotherapy; immunotherapy: experimental protocols, clinical trials and on-going studies.

Free papers will be submitted to the Scientific Committee.

The proceedings and reports from invited speakers will be published.

Abstracts, subscription and registration fees (600 FF or 140 Dollars) are to be sent not later than February 15th 1980 to the General Secretary.

The number of inscriptions will be limited to one hundred.

Organizing Committee:
Dr J.B. Dubois (Montpellier)
Dr B. Serrou (Montpellier)
Dr Cl. Rosenfeld (Villefjuif)

Further information can be obtained form Dr J.B. Dubois, General Secretary, Centre Paul Lamarque, Hopital Saint Eloi, B.P. 5054, Montpellier, France. W358M

Post-Graduate Research Assistantships

Two posts are available to join a small research team working on genetics and genetic manipulation in bacilli. Applications are invited from well qualified graduates with a degree in Biochemistry, Microbiology, or related subjects, for:

1. Research on the development of genetic manipulation in bacilli and other gram-positive microorganisms. Applicants should have a good background knowledge of Microbial Genetics/Molecular Biology and be interested in the existing techniques of Genetic Manipulation.
2. Research into the genetics of thermophilic bacilli and their bacteriophage. Applicants should have a strong interest in Microbial Genetics/Molecular Biology.

The posts are funded by a research contract with the Health & Safety Executive and are tenable for up to 3 years.

Salary will be in the range £3,486 to £4,935 increasing to £3,807 to £5,316 on 1.1.1980. NHS terms and conditions of service.

These posts may be discussed informally by contacting A. Bingham or R. Sharp; Tel. 0980-610391, Ext, 371/394.

PHLS

Applications including curriculum vitae and two academic referees should be sent to Mrs. M. Bushby, Personnel Officer, CAMR, Porton Down, Salisbury, Wilts. Closing date 5 October 1979.

3246(P)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MICROBIOLOGY

Applications are invited for a Postdoctoral Research Assistantship financed by the SRC for work on biochemical and genetic aspects of anaerobic energy metabolism in *E.coli* involving DNA cloning and the control of expression of several cloned functions. Tenable from October 1979 for three years. Starting salary up to £5,199 a year.

Applicants should possess or expect soon to possess a PhD in molecular biology, genetics, microbiology or biochemistry.

Applications, including curriculum vitae and names of two referees to Dr JR Guest, Department of Microbiology, the University, Sheffield S10 2TN as soon as possible. Quote ref: R364/G. 3248(P)

THAMES POLYTECHNIC

SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH ASSISTANTSHIP

Applications are invited for a Research Assistant to undertake, under the supervision of Dr A R W Smith, an investigation into the pathway of degradation of the herbicide 2,4-dichlorophenoxy acetic acid (2,4-D) and its induction in *Acinetobacter* sp. The post is tenable from 1 November 1979. Applicants should hold a good honours' degree in biochemistry or chemistry, and some experience in microbiology is preferable, but not essential.

Salary scale: £3,321 to £3,705 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by 2 October, 1979. 3245(P)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMISTRY

Applications are invited from men and women for an

SRC POSTDOCTORAL RESEARCH ASSISTANTSHIP

to study the photochemistry of carbanions and, in particular the cis-trans photoisomerisation of diphenyl-allyl and related anions. Experience of vacuum techniques for handling reactive compounds and/or photochemistry or photophysics (flash photolysis, measurement of fluorescence lifetimes and spectra) needed. Tenable for up to three years from 1 October 1979 or as soon as possible thereafter. Salary on range 1A at a point dependent on age and experience. Applications naming two referees to Drs B. Brocklehurst and R.N. Young, Chemistry Department, The University, Sheffield S3 7HF, from whom further information can be obtained. Quote ref: R343/BF/G 3256(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited from graduates, preferably with PhD in the field of High Energy Astrophysics, for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

tenable for three years from as soon as possible. The successful candidate will join a research group working in experimental Gamma Ray Astronomy and should preferably have some experience in the field of digital and analogue electronics. Experience with balloon borne experiments would be an advantage.

Salary on National Range 1A £4,333 to £7,521 per annum plus superannuation.

Applications (3 copies) naming three referees should be sent by 28 September, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 3271(P)

FOR SALE and WANTED

THE MYTH OF SCIENCE, or The fantasy of truth by Frederick R. Schram

Tells what science is and how it is done, what its limitations and weaknesses are and how these can affect public and private life. Focuses on 2 common myths: that science is methodical and objective, and scientists are rational, open-minded men and women. Examples from history and recent headlines make timely and hard hitting points.

System for trace elements analyses

The BÜCHI Digestor 445 sets new standards in sample preparation!

Convincing advantages

- fully automated system for the digestion of large samples
- sample weight up to 30 g
- simultaneous digestion (ashing) of 6 samples in quartz-glass flasks
- small quantities of reagents – no contamination
- no loss of trace elements during digestion
- high reproduceability
- sealed fume exhaust unit
- stepless regulation of the digestion temperature between 150–400°C.
- salt bath – safe and clean operation
- cooling system for exhaust tubes
- rotation of flasks

We are interested on your Digestor 445.
Please send us your detailed information.

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

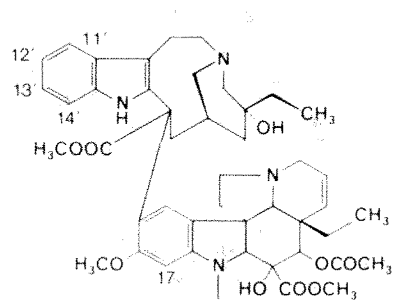
Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:



[G-³H]VINBLASTINE
Code TRK.507

17	44%	11′	8%
12′,13′	46%	14′	2%

[1β, 2β(n)-³H]TESTOSTERONE
Code TRK.162

1α	5.9%	2α	8.2%
1β	46.0%	2β	39.9%

[6-³H]BENZO[a]PYRENE
Code TRK.501

6	>95%	1	<5%

D-[2-³H]GLUCOSE
Code TRK.361

2(α)	40%	2(β)	60%

L-[3,4(n)-³H]VALINE
Code TRA K.533

2	8%	4	64%
3	28%

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

David Davies, the present Editor of *Nature*, will be leaving at the end of 1979 to become Director of the newly-formed Dartington North Devon Trust. The purpose of the Trust will be to find ways of improving life materially and otherwise in a rural area, through industrial innovation and through the introduction of new ideas in education, housing, leisure and the arts.

An announcement concerning the appointment of a new Editor is on page iii, opposite.

Editor of Nature

Applications are invited from those wishing their names to be considered for this appointment, which will become vacant at the end of this year.

A brief account of past career, qualifications and experience considered relevant should be sent in writing to:

nature

As easy as 1·2·5

If you've been wishing you could get rid of the inconvenience and difficulties of iodinating proteins, here is an easy way to do it. Get our simple, reliable Radioiodination System [^{125}I] – everything you need, ready for your protein.

We've selected a mild reaction method (enzymatic lactoperoxidase) to preserve your protein specificity. We've made sure that there are no contaminants to interfere with proper iodination. And we've tested each lot in a complete iodination procedure.

The ingredients are: Sodium iodide [^{125}I], iodination reagent, sodium phosphate buffer, 1% β-D-glucose to activate the system, and a volatile radioiodine trap.

This system is the new way to make iodination straightforward and reliable. Send for the protocol to start saving time and trouble.

Not for use in humans or clinical diagnosis.

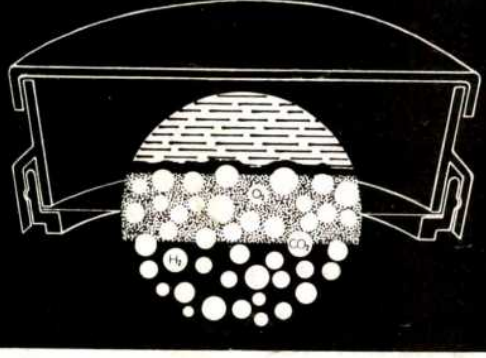
A new approach in tissue culture



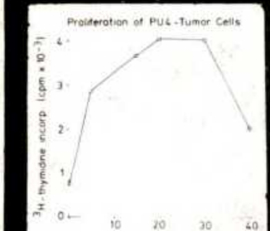
PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

HEPARIN-ULTROGEL® A4R

Affinity chromatography adsorbent for:

- coagulation factors
- lipoproteins
- lipoprotein lipases
- protein synthesis factors
- DNA and RNA polymerases

Main characteristics:

- Immobilized heparin per ml of gel: 4 - 6 mg
- Adsorption capacity:

- bovine AT III	: 1.3 - 2.3 mg/ml
- protamine sulfate	: 7 - 10 mg/ml
- toluidine blue	: 2 - 3 mg/ml

- Temperature stability: 2 to 120° C.

Fluorescence, light scatter, cell sorting

COULTER® have a family of compact reliable instruments that can help you investigate a wide range of cytochemical, histochemical and immunological characteristics. They are the COULTER® Model TPS Cell Sorters.

Select from 5 watt, 2 watt lasers, one or two analysis UV capability and other features to meet your research needs.

Study immunological response, the DNA or protein content of a cell, its surface structure, whether it is alive or dead, how big it is and many other things based on laser-induced fluorescence and/or light scattering.

TPS Systems analyse at rates up to 10,000 cells per second. They also physically sort out cells of interest based on operator-selected parameters at rates up to 4,000 per second.

I am interested in hearing more about the COULTER® TPS cell sorters.

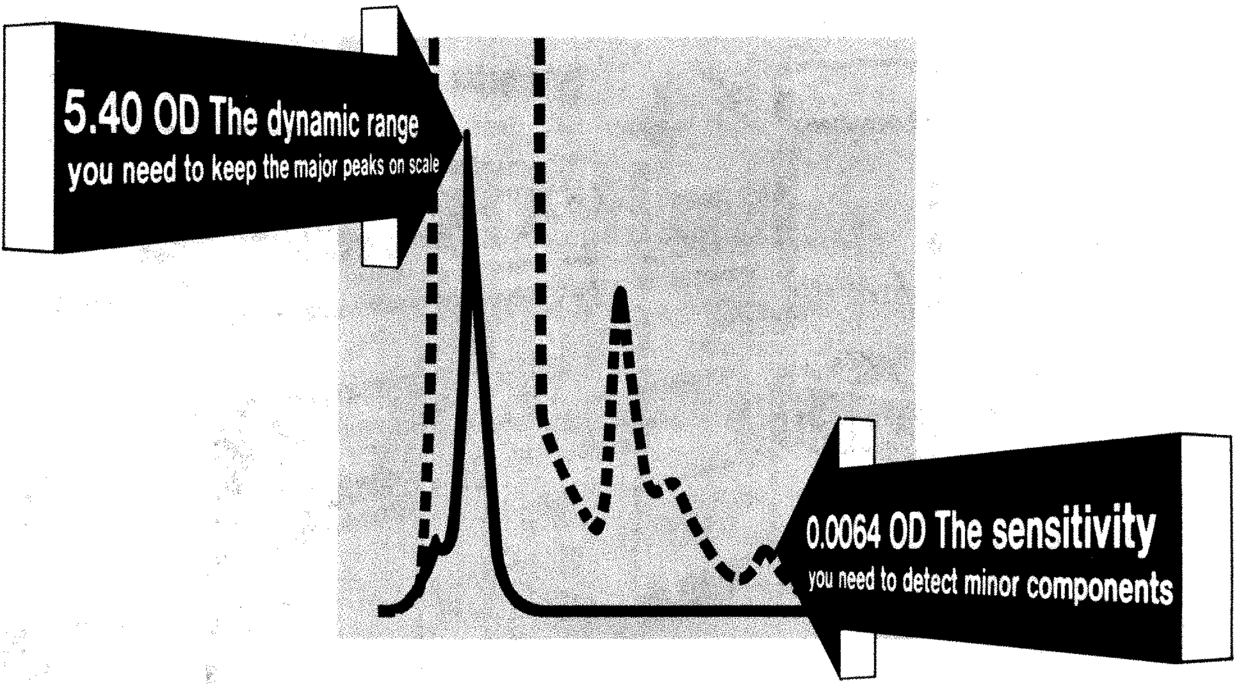
Now you can have it both ways!



5.40 OD The dynamic range
you need to keep the major peaks on scale
0.0064 OD The sensitivity
you need to detect minor components

Pharmacia Dual Path Monitor UV-2

has a unique flow cell with two optical path-lengths for new versatility in UV-monitoring.

● Monitor absorbance quantitatively up to 20 OD units full scale with a sensitivity of 0.005 OD units full scale at the same time, in the same run.

● Monitor at 254 nm and/or 280 nm with two completely independent measuring systems.

The Dual Path Monitor UV-2 has all the other features you expect of a high performance monitor: stability, cold room operation convenience and compact design. For less-demanding applications you can choose the Pharmacia Single Path Monitor UV-1 with a choice of 3 mm or 10 mm flow cell and operation at 254 nm or 280 nm.

Find out more about the practical advantages of column monitoring with the UV-2 and UV-1 Monitors. Ask about the Pharmacia Recorders too.

The nuclear 1980s

Two events coming up in 1980 will influence the world's nuclear future for many years. In the spring the International Nuclear Cycle Fuel Cycle Evaluation (INFCE) will issue a report that is the result of nearly two years of study by eight working groups. Then a few months later, upwards of one hundred nations — signatories to the Non-Proliferation Treaty (NPT) — will convene for their second five-yearly review of the treaty. The events are by no means unrelated. They both reflect efforts in the world community to come to grips with the problem of capitalising on the peaceful benefits of nuclear power without opening the door to nuclear weapons. And neither, in their different ways, will be able to hold out much hope that there is any simple way forward, either in terms of technological fixes or new institutions, which will make the 1980's a time when nuclear weapons stop spreading into yet more hands.

INFCE, the backwash to President Carter's 1977 initiatives to arrest proliferation by unilateral and widely disliked measures, is likely to deliver a fairly comfortable message to nuclear states — not great surprise given the representation of nuclear enthusiasts on the working parties and the absence of any brief to consider broader issues such as environment or safety. At a meeting of the British International Studies Association last week, Dr S. Warnecke indicated that the conclusions will probably run something like this: there is no geological shortage of natural uranium although there could be political problems in international sales; if there is need for some more enrichment capacity this should be confined to technologically advanced countries (such as Japan); there is wide divergence between countries on the economic sense of reprocessing (the United States failed to get any measure of consensus on the desirability of once-through cycles); the non-proliferation risks associated with fast-breeders are no greater than those of light-water reactors; and there is as yet nothing in advanced reactor concepts which would inherently make them more proliferation-proof than current designs. In short, the path that major nuclear nations have been taking these past ten years is neither free of proliferation risks nor is it recklessly dangerous, and no other path holds out any obvious attractions of more proliferation-proof power. This is hardly going to be a surprise to the nuclear bureaucracies of the world, although it may well disappoint President Carter who at one time hoped that INFCE would provide some international agreement on positive steps that could to be taken to keep the danger of proliferation out of the nuclear fuel cycle.

The message of INFCE to the NPT Review Conference will be, then, that it is difficult if not impossible for the international technoligical community to do much in the final analysis to prevent the spread of nuclear weapons — a nation with a strong political will to go nuclear can easily overcome such technical obstacles as are put up. This gloomy view will coincide with unencouraging news on other fronts. On Article VI of the treaty, in which nuclear-weapon states promise as their part of the bargain to work for disarmament, there is relatively little to present except an uncertain and unimpressive SALT 2, and glacial advances towards an almost meaningless (because temporary) comprehensive test ban treaty. Futhermore the last five years have seen the emergence of a different and ominous sort of proliferator — the nation which, because of heavy hints, must be assumed to be acquiring a nuclear weapons capability even though it doesnt take the final step of firing a device.

Can the NPT survive all this? In a formal sense, yes; no doubt for the next few years it can retain all its signatories, and it must never be forgotten that there are some very desirable names on the list. But as time progresses the treaty looks more and more like every other arms control measure — a limitation only on those who have no particular desire to transgress. □

. . . and the broadcasting 1990s

The World Administrative Radio Conference starts this week in Geneva and is expected to run until December. Public interest is likely to focus on the allocation of frequencies, and more particularly the North-South and East-West political conflicts inherent in these allocations. But one issue which could do with much more public exposure is the question of the accessibility of television transmissions.

Radio broadcasts, with the help of the ionosphere, know no national frontiers, and as a result there is a richness of choice open to anyone with even a modest receiver. The present, ensured that it has been much more of a national affair. As a consequence access to a mass audience has been in the hands of a relatively small number of people, all with similar cultural backgrounds.

Satellite television could change all this. Within ten or fifteen years it could be possible to tune in to French, German, Italian or Russian television by directing a rooftop aerial at the appropriate satellite. The trouble is that not every country wants its people to have that freedom, which the objectors term cultural or political subversion.

As a result a 1977 conference went to great lengths to ensurey, by means of satellite placings, polarisations and radiation patterns, that the cause of international understanding is not going to be given much of a boost by television.

Time is running out for brave enterprises to resist this narrow nationalism. The Geneva meeting could be the last opportunity for anyone to raise a voice against it. □

Battle heats up over control of workers' health

The US Occupational Safety and Health Administration will soon face one of the severest political challenges of its ten-year existence. In the second of three articles on the current anti-regulatory mood in Washington **David Dickson** reports on pressures on the agency and their implications for environmental research

Within the next few weeks a Senate Committee will begin discussing two bills either of which could, if implemented by Congress, significantly restrict the activities of the Occupational Safety and Health Administration (OSHA).One proposes a partial exemption for a large number of companies from the provisions of the act which set up the agency in 1970; the second is a stronger bill which would mean total exemption for small businesses removing the agency's jurisdication over more than four million workers.

Attempts to limit the activities of OSHA — perhaps the federal agency least loved by the US business community — have frequently been launched in Congress, but have seldom gathered much momentum. This year, however, the situation of different. Defenders of the agency have less support than previously; while critics, buoyed by their success in securing an amendment to OSHA's appropriations bill which effectively bars the agency from routine safety checks on 1.5 million establishments, are confident that at least one of the new bills may reach the statue book.

Disenchantment with OSHA has been directly fuelled by the anti-regulatory mood that is increasingly dominating both the Congress and the administration. Much of this has its roots in the economic argument that excessive regulation has been an important contributor to inflation, in particular reducing the rate of technological innovation and thus slowing productivity growth.

But behind this there is a political argument over who should have prime responsibility for protecting the health of the worker. Whether it should be the federal government, in its role of social regulator; or whether the responsibility should be passed partially back to private industry, operating under broad government guidelines, but responding primarily to economic incentives and the dictates of the market-place.

Support for the latter view is growing in strength. But to the extent that such sentiments have already been relected in various Congressional actions, they have been strongly condemned by the trade unions. In a report on recent and current legislative moves, for example, the United Steelworkers of America says that 1978 and 1979 were "dismal" years in Congress for workers safety and health.

"The errant pot shots that had been fired at OSHA every year since its enactment have now improved in their accuracy and their potency, and real erosion is beginning to take place", the union says.

The seeds of the present conflict between supporters and critics of OSHA were sown in the 1970 act establishing the agency. This requires OSHA to work towards achieving a "safe and healthful" environment for every US worker — but gave little specific indication as to which criteria should be used to make this assessment.

Initially OSHA came under steady fire for appearing to concentrate on "nit-picking" issues, such as the height of fire extinguishers above the floor, and ignoring many of the more important health and safety standards.

Its image of ineffectiveness and petty-minedness has been successfully revamped under OSHA's present head, Dr Eula Bingham. Appointment by President Carter in 1977, Dr Bingham has shifted the main emphasis from safety to health — a move reflected in the fact that OSHA has produced more health standards in the last two years than it did in the previous six.

Agency officials point to one of its major successes as being an increased public awareness of the importance of occupational health as a social issue. But they acknowledge the paradox that this has occurred precisely at a time when there are growing demands for the government to reduce its regulatory activities; and that this puts OSHA and its supporters in a vulnerable situation.

Evidence of this shift in public mood is provided by the speed with which even "liberal" politicians are now jumping on the regulatory band-wagon. The more restrictive of the two proposed Senate bills, for example, has been submitted by Senator Franch Church of Idaho, considered a liberal in US politics, but facing a tough challenge from the right in his re-election battle next year.

"Having someone like Church, who we do not consider an enemy, against you makes things a lot harder to deal with," says George Taylor of the AFL-CIO (American Federation of Labour — Council of Industrial Organisations), who foresees a need for the unions to "fight like hell" to protect some of the gains made in recent years.

It has become politically acceptable to challenge the activities of regulatory agencies. Speaking at a meeting of the American Chemical Society in Washington two weeks ago, for example, Dr P M Nortling, director of health and safety for the Du Pont Chemical company, said that although the number of citations for illegal practices issued by OSHA had diminished over the past two years, the proportion challenged by industry had almost doubled, from seven to 12% over this period.

Corporate attitudes

"There has been an important change in corporate attitudes. In the past, corporations were unwilling to appear obstructive on health and safety issues. That reluctance is now giving way, and we are now seeing the chemical industry taking a very active role in challenging regulatory proposals, particularly those which we feel impose economic burdens incommensurate with the expected benefits," Dr Norling said.

Ironically many of the current controversies result from a surfeit of laboratory data about the physiological effects of particular substances — at least when compared to the relative lack of epidemiological data on human health implications of the type which can be used as a solid basis for regulation.

A typical case in point it OSHA's proposal to implement "generic" carcinogen controls and standards. Under this proposal, first put forward two years ago and expected to be published in its final form next month, the agency will classify as a carcinogen any substance known to produce tumours in any single species of laboratory animal — and will demand that

Above: working in a steel foundry

0028-0836/79/390244-02$01.00

occupational exposure to this substance should be reduced as low as technologically feasible.

OSHA scientists argue that, given the many uncertainties that surround the mechanisms of carcinogenisis, workers should be given the benefit of the doubt. And this means protecting them against any substance bearing the least suspicion of carcinogenic properties.

The chemical industry, on the other hand, has attacked this approach as being both unnecessarily expensive — it quotes a cost for implementing the proposals as between $8 and $88 million — and as inherently "unscientific". The industry argues that more substantial data is required before taking such drastic action; this might, for example, include classfying carcinogens in terms of relative potency.

The industry has formed a lobbying group, the American Industrial Health Council, specifically to challenge OSHA's proposals — referred to last week as an "administrative short-cut" by AIHC executive director Ronald A Lang.

One AIHC proposal meeting with more sympathy in the administration, however, is that there should be a clearer distinction between the scientific and the political decisions made in the regulatory process. The AIHC has proposed that the National Academy of Sciences appoint a panel of "the best scientists the government can tap" to assess whether a particular substance is or is not a potential human hazard, and if so to what degree. The appropriate control mechanisms would them be agreed by a separate body.

A similar, although not identical, two-stage process for dealing with occupational hazards is already being developed within the administration, using the Department of Health, Education and Welfare's National Toxicology Programme to centralise the scientific assessment of potential hazards; and further developments along these lines are expected to be contained in a report from the President's newly apointed Regulatory Council, due in a few weeks time.

Even though such centralisation may have advantages in terms of efficiency, however, not everyone is totally convinced of its merits, some fearing that it might put a strait-jacket on the flexibility made possible by a plurality of programmes. "If there is an indication that these joint programmes are used to explore certain questions and to neglect others, that will be a real problem," says Dr Robbins of the National Institute of Occupational Safety and Health.

But the pressures to change the whole shape of Washington's regulatory apparatus continue to build, Until a few months ago, the dominant demand was that this apparatus should be "rationalised" in the interests of cost effectiveness. More recently, there has been what Dr Frank Press, director of the Office of Science and Technology Policy, has referred to as the emergence of a "new philosophy" emphasising economic incentives rather than regulatory clout.

Speaking at the ACS meeting two weeks ago, Dr Press suggested that industry should be given more flexibility in deciding how to achieve overall regulatory goals established by society. This could be done, for example, by applying the "bubble concept" used for air pollution control — requiring merely that a plant's total effluence release complies with federal standards — to health and safety.

"One of the important things to recognise regarding this approach to regulation is that it provides new incentive to industry to innovate. It takes some of the repressiveness and uncertainty out of regulation, and relies more on market-forces to achieve the desired goals in environmental quality, health and safety."

New legislation along these lines may well emerge in the next few weeks, when President Carter announces the conclusions that he has reached following a year-long review by the Department of Commerce of the effects of government policy on industrial innovation; the forty recommendations passed to the White House for presidential decisions include a number on regulatory reform, including for example a proposal to shift from design to performance criteria as the basis for regulation.

A number of observers in Washington feel that, with an election year approaching, it would be difficult for the President to support any major roll-back in occupational safety legislation — if only because trade union support is probably more important than that of environmentalists who have complained of the impact of proposed energy legislation.

But within the administration there is considerable dispute over whether the incentives approach is the right one to take. OSHA, for example, has been strongly opposed to demands that health and safety regulation should be justified on economic grounds, arguing in particular that there is no way that a worker's health can be adequately quantified — and certainly not by putting a market value on it.

US textile worker: stringent limits to cotton dust exposure have been one of OSHA's recent successes

Indeed almost all sides in the dispute on an appropriate policy now seem to accept that the vagaries of cost-benefit analysis are such as to make it an inadequate basis for regulatory decision-making — and that no statistic can really be trusted to give a full reflection of either the costs of regulation or its benefits.

As far as Congress is concerned, the response has been explicitly political. "Ultimately out belief is that the protection of the work-force is the responsibility of the employer, working with the employee, not of the OSHA policeman holding a club" says Mark de Bernardo of the Chamber of Commerce, a Washington-based group representing private industry interests which is providing active support to legislative attempts to change OSHA's mandate.

Trade unions

Trade unions and their supporters, however, see things differently. Although critical of the relative lack of impact which OSHA has had in the past, they credit it with many important gains, for example some of its recent programmes in worker education. And they are convinced that the health of workers can be better achieved through an effective regulatory agency rather than through the collective bargaining process.

"Protecting the gains made by OSHA is going to require vigilance and hard work," says George Coling of the Urban Environment Congerence, a lobby group which has been engaged in developing a coalition of labour, environmentalist and minority groups on occupational health issues. "It is not a battle for the agency, but it is a battle for health — and the agency is the tool that we need."

Ironically, the one aspect of federal health and safety efforts which has so far been relatively immune from Congressional attack has been the research budget. The budget for NIOSH, for example, is scheduled to increase by 25 per cent for the fiscal year 1980, reflecting the administration's commitment, articulated through the science adviser's office, to improve the "science base" of its various spheres of activity.

Yet even this may have its price. "It is possible that Congress may want to put more money into research rather than into adequate reinforcement. We obviously welcome the extra funds; but in the long-run such a shift in emphasis would not be a good thing; it might mean that we could produce more results, but it would give the administration less ability to put these results into practice," says Dr Robbins of NIOSH. □

Next week: problems with non-proliferation

Scientists leaked H-bomb secrets, says US

US Government experts believe that the authors of two press stories outlining the concepts behind the hydrogen bomb may have been helped by leaks from scientists at the government's own Lawrence Livermore and Argonne national laboratories.

The government had tried to stop publication of an article by Howard Morland entitled "The H-bomb Secret — How We Got It, Why We're Telling It" in the *Progressive* magazine. However, the government dropped its case after the publication last week of a lengthy letter outlining the details of the H-bomb in a Wisconsin newspaper, the *Madison Press Connection.*

The letter, written by a computer-programmer, Charles Hansen, has roused. the suspicions of government nuclear experts, who claim that Hansen used leaks from the government's secret files in its case against the *Progressive* in addition to repeating the mistakes made by Morland in his article. As for the latter, the government claimed in a brief that "The evidence suggests that Morland was able to write accurately about the H-bomb secret only because he had significant guidance by a person or persons with access to classfied material".

Both authors insist that they based their articles on information available to the public in libraries, lectures, and textbooks, and that the similarities in the two articles could be explained by the fact that they used the same sources.

Despite the decision to drop the *Progressive case,* the legal battles are not over, since the government has now asked the Justice Department to determine whether there is a case for criminal prosecution under the Atomic Energy Act.

But lawyers on both sides have doubts as to whether a firm case could be made. The lawyers for the *Progressive* argue that the Act is too loosely defined for a successful prosecution; and some lawyers in the Justice Department believe the government's case would be fundamentally flawed, as the many of the "secrets" are already in the public domain.

Anne Norman

Poland seeks cooperation on nutrition

Fundamental research into human nutrition, including data gathering and the design of experiments suitable for use on human subjects, should become a major area of international cooperation, Professor Kazimierz Szebiotko of the Poznan Agricultural Academy told *Nature* last week. He was attending a UK/Polish symposium on food technology at the National College of Food Technology, Weybridge.

Poland already has a well-developed programme of food research. Protein production and its optimum use rates as a "governmental problem" in the Polish hierarchy of research and development, "commanding the highest priority. The eight-point programme ranges from plant genetics to unconventional protein production, and from the biochemistry of aminoacids to the optimum animal feeds.

So far, said Professor Szebiotko, results have been generally better than expected. A soya-bean has been developed with the shorter growing period necessary for Poland, and already some 500 ha have been grown successfully. In collaboration with a Canadian team, a strain of rape-seed has been developed with very low content of erucic acid (suspected of being a carcinogen).

There have, however, been setbacks. A project for processing inconveniently small fish and fish scraps into edible form turned out well — but ran into trouble when fish stocks declined. There are certain logistic difficulties; in his own field of single-cell protein production from agricultural wastes, Professor Szebiotko said, developing the process was fairly straight forward. What was needed now was research into the "economics of cooperation with industry".

This did not seem to have been the case, incidentally, with TVP. According to Professor Jan Zaleski of the Ministry of Food Production, who led the delegation, for some years now all Polish hamburgers, mince and many kinds of sausages have contained TVP "extender" (20% in the case of hamburgers and about 12% for sausages), the new recipe being quietly introduced and the non-extended product simultaneously phased out by agreement between the Ministries of Food Production and Health — without any indication to the public. This, incidentally, was not the best procedure in Professor Szebiotko's opinion. He would have preferred the open launching of frankly soya lines.

In the future, he hoped, genetic engineering would form a fruitful field of international cooperation. Other such "themes for the future", to be tackled at the international level, he suggested, might include the biochemistry of nitrogen fixation, the optimal use of water resources (also a major concern in Poland), and his own particular interest, optimal nutrition.

So little is known about this, he stressed, while so much work has been done on malnutrition and obesity. What is needed, he suggested, is a data-bank of nutritional experience collected over the whole world, No one country, or even group of countries, could undertake this. It is a task for the United Nations agencies, for WHO and FAO.

Vera Rich

Cubans to join the space race before 1983

Cuba's future cosmonauts have received special training and acclimatization to enable them to cope with a possible landing in the Siberian winter, the chief training officer of the Interkosmos programme, former cosmonaut V. A. Shalato, told a Moscow press-conference recently, despite the fact that Soviet space planners are usually reluctant to give any details of future plans or cosmonaut training.

The press conference was, formally, a winding up of the latest series of Salyut-6 missions. The emphasis on future Cuban participation does not necessarily indicate an imminent Cuban launch. It could simply be a response to the Havana non-aligned conference and the large Latin-american presence at the press-conference.

Shalatov would not commit himself to a date for the Cuban launch, recalling only that it was originally announced that all the Comecon allies would have had a cosmonaut in orbit by 1983, and that "we have every reason to think we will meet this date, or perhaps it will be a little earlier." He did, however, say that the Cubans had completed their general theoretical work and had now moved on to crew training.

At present, the two candidates are officially on holiday in Cuba, (where incidentally, Interkosmos maintains a cosmonauts' rest home), One of them has also been taking examinations at Havana University.

Meanwhile, according to Academician Boris Petrov, Chairman of the Interkosmos council, the programme of on-board experiments proposed by the Cuban scientists for the future cosmonauts to perform is undergoing expert scrutiny by "specialists of both countries".

Vera Rich

"If they're gonna put a Cuban in space maybe we can fix it to be Fidel Castro!"

0028-0836/79/390246-01$01.00

Lake Balaton: going green

HUNGARY's Plant Protection and Agrochemical Service was originally established 25 years ago to boost agricultural production by the proper application of modern fertilizers and pesticides, a task which it carries out efficiently and well from its 20 sophisticated research centres (one in each county and one in Budapest). During the last three years, however, the centres in Zala, Veszprem and Somogy counties have taken on an additional role, the protection of the water quality of Lake Balaton. This is a task of some urgency: a recent report to the Hungarian government stated that with the present rate of chemical input, and no preventive measures, the majority of the lake will be green with eutrophication and unacceptable for leisure use within 15 years.

Lake Balaton is the largest body of fresh water in continental Europe with an area at mean water level of 595 km^2, and it is Hungary's main holiday area. In 1963, a special government decree pronounced that the region should be developed primarily to meet the needs of domestic and foreign tourism. A number of highrise hotels sprang up along the lake shore — not always with sufficient attention to effluent disposal.

The main problem, however, is agriculture in the catchment basin, an area of some 5,180 km^2, excluding the lake surface. The main crops are wheat, maize, rape and, on the northern shore, grapes. Modernisation of agriculture has led to a considerable increase in the use of agricultural chemicals. By 1975, the average concentration of active nitrogen phosphorus and potassium substances (NPK) had reached 400 kg/ha in Somogy county, 330 in Veszprem, and 380 in Zala. The daily discharge into the lake via the river Zala and other feeders was 764 kg of total phosphorus and 1,600 kg of total nitrogen from plant nutrients, with an additional 254 kg of total phosphorus and 533 kg of total nitrogen from treated effluent.

To exacerbate the problem, environmental protection in Hungary was covered by a piecemeal series of laws until as recently as 1976. These were often outdated, as, for example, a 1947 order of the Ministry of the Interior which made it an offence to encourage draught animals by shouting. In 1976, however, a new and comprehensive act came into force: "On the protection of the human environment". To implement this legislation, the former Office of the Environment was upgraded and given independent status as the State Council for the Environment and Nature Conservation, with a secretary of state, Dr Gyorgy Gonda, at its head. To deal with the specific problem of the Balaton area, a Coordinating Council for Research on Lake Balaton was established under the auspices of the Academy of Sciences, headed by Dr Istvan Lang, Deputy General Secretary of the Academy.

A complex ecological research programme was inaugurated, originally with some 200 subjects on the agenda. After what Dr Lang describes as "repeated professional consultations" these were finally whittled down to three priority research areas: factors characterising, impairing or improving water quality in the lake; the social sciences background to environmental decisions in the region; and the environmental factors affecting recreation and tourism. In addition, two longer-term studies were also given priority status: the review and synthesis of the principal scientific results and professional experience relating to the region, and the working out of the scientific basis for an integrated monitoring system.

Some 40 research institutes, university departments and industrial research laboratories were drawn into the project. Government guidelines indicated that the lake water from now on must be used for drinking and recreation only; even treated effluent is to be excluded. While civil engineers and architects are busy on a crash programme of sewerage development, the three plant protection stations in the counties bordering the lake have joined forces with the National Water Authority to monitor and prevent the run-off of chemicals.

Close to the lake and its tributaries, an upper limit of 160 kg/ha of active NPK has been set, with some pesticides and fertilizers forbidden completely. The restricted zone is normally 1 km wide, measured from the bank, with very severe restrictions south of highway 71 on the north shore of the lake. Although a reduction in fertilizer use should lead to decreased crop yield, recent rises in the price of fertilizers have raised the general question of how cost-effective it is to apply massive doses of fertilizer. Many of the erstwhile lavish cooperatives are in any case settling for slightly lower yields. One of the main research subjects for the Plant Protection and Agrochemical Service is how to increase crop-yield without increasing the amount of fertilizer used. As far as pesticides are concerned, the Plant Protection and Agrochemical Service was already operating a compulsory soil and residue monitoring service for food crops. In the three lake counties, this was extended, in 1976, to the monitoring of pesticide run-offs. After an initial survey carried out together with the National Water Authority, a set of soil and water sampling sites were chosen at random positions. These sites are monitored every fortnight or month (according to agricultural conditions). According to Dr Sandor Bordas of the Budapest Plant Protection and Agrochemical Station, it is now possible, on the basis of the last three years' results "to follow the dynamics of pollution, and to have a regular view of the quality of water and soil in relation to pesticides".

Balaton fisherman mends his nets

According to the research team at the Zalaegerszeg Plant Protection and Agrochemical Station, the new restrictions will have little overall effect on the region's agriculture. With some crops, however, there may be "difficulties". Vine-growing, in particular, is now very difficult in the restricted zone of the north shore, and the biological research institute at Szeged has started research into disease-resistant strains, which would reduce the need for pesticides. So far, however, no variety has been obtained that is entirely resistant to *Plasmopora viticola* (downy mildew). Should vinegrowers wish to restock, they explained, the government will give direct financial assistance to state or cooperative vineyards. Much of Hungary's viticulture, however, takes place in the private sector, on the small 'household plots' which provide some 30% of all Hungary's crops. Small growers wishing to make the change-over, said the Zalaegerszeg team, get 8 years free of tax on the new vineyard.

The small grower, incidentally, is potentially one of the weak links in the whole plant protection service. On cooperative and state farms, the use of agricultural chemicals is strictly controlled by specially trained Plant Protection Engineers. No such restrictions can be imposed on the private grower — other than by limiting the sale of the most sophisticated products to the state sector. Theoretically, then, there is nothing to stop the owners of summer cottages on the north shore from pouring unacceptable concentrations of fertilizer on to their gardens — except a growing public awareness with ecological problems, which is currently being promoted by a massive campaign in the media.

Vera Rich

news in brief

Pillinger wins appeal against dismissal: A UK employment appeals tribunal has ruled that Dr David Pillinger was unfairly dismissed from his post as a research biochemist at the Christie Hospital in Withington near Manchester. Pillinger, 40, had held a permanent post at the Christie since 1962 but was made redundant when the Medical Research Council failed to fund an experimental chemotherapy project he was working on (28 January). A previous tribunal ruled against Pillinger but on appeal Mr Justice Flynne found that the redundancy was "grossly unfair" since the hospital did not make an effort to find out why Pillinger's grant was denied. The hospital will now apply to the Court of Appeal for leave to appeal and if this is granted it will present its case to the Court later in the year. In the meantime Pillinger is without compensation. Even if the Court of Appeal finds in his favour he will have to face a further tribunal to obtain remuneration for the damages caused by his dismissal.

Two hundred demonstrate for Piperno in Paris: Demonstrators marched through Paris last week in support of Franco Piperno, the Italian physicist and left-wing political activist who is threatened with extradition to Italy for "activities directed against the State". Piperno has drawn support from intellectuals in both France and Italy against his extradition. In Paris, the Comité des Intellectuels pour l'Europe des Libertés (CIEL) — an organisation of leading European intellectuals headed by playwright Eugene Ionesco — issued a statement last Thursday oposing a renewed demand for Piperno's extradition by the Italian authorities. "The rules of jurisprudence are opposed to an extradition based on manifestly political motives. The Paris court refused this extradition the first time and the Italian judge, seeing the inanity of his first formulation has prepared a second dossier consisting of an improbable judicial patchwork of no less than 46 indictments." In Italy, 50 Italian intellectuals, including writer Romaine Gary and film director Bernardo Bertolucci have expressed their opposition to the arrest of Piperno in Paris and the persecutuion of other activists in the Workers Autonomy Movement, an independent political grouping to the left of the Italian Communist Party. The Paris Court of Appeal will examine the second extradition request on 26 September.

Canada announces inquiry into nuclear energy: The Canadian Minister for energy, mines and resources, Mr Ray Hnatyshyn, announced last week that the Canadian government is planning an open parliamentary inquiry into "the whole field of nuclear energy". In a speech to provincial mines ministers in Winnipeg, he said that the inquiry will be conducted by a parliamentary committee, but that the government did not intend to place any type of moratorium on the further development of nuclear power during the inquiry. Full details of the nature and scope of the inquiry are to be decided after the Canadian parliament reconvenes in October.

French unions find fault with reactor part: Two French trade union federations, the CFDT representing metallurgy workers and the CGT representing workers in the energy industries, have announced "important" faults in the fabrication of a part destined for French nuclear reactor assemblies. The two federations made their announcement in a letter to the Minister for Industry, M. Andre Giraud, on 22 September. An official inquiry has been ordered into the origin and evolution of the fault. The fault in question consists of fissures from 7 to 8 millimetres long and 6 millimetres deep in the tubular plates of the heat exchanger-steam generator, one face of which has contact with the water from the primary reactor cooling circuit. The CFDT says that with some 20 reactors affected, French on-site safety measures are not adequate to deal with the situation. The CGT while saying that there is no immediate hazard is calling upon its members not to start up the reactors without "fully guaranteed security conditions." A decision will be made at the end of the month whether to start up certain reactors or not.

US nuclear fuel factory shut down: The director of the Nuclear Regulatory Commission's safety division has ordered the shutdown of a factory that manufactures fuel for US Navy nuclear submarines. The factory was closed after an NRC inventory revealed that a significant amount of highly enriched uranium was unaccounted for. The exact amount has not been disclosed but regulations stipulate a shutdown within 72 hours if more than 19.8 pounds of uranium is missing. The Nuclear Fuels Services Inc. facility which is located in Erwin, Tennessee has had a history of problems. In April 1977, the factory was fined $53,000 by the NRC for failure to provide adequate security services. The facility will remain closed for 45 days while a complete uranium inventory is made.

US Navy tested germ warfare on San Francisco: The US Navy blanketed 117 square miles of San Francisco with an aerosol spray of bacteria in 1950 in an attempt to measure the effects of biological warfare, according to recently released military records. For six days in September 1950, a Navy ship released an aerosol containing *Serratia* sp. bacterial (thought to be harmless at the time) over the city. In spite of a subsequent outbreak of *Serratia*-related pneumonia the Navy kept quiet about the tests until last week when documents were released to the family of Edward Nevins, a victim who died during the outbreak. The family is suing the Army for $11 million. The Nevins case raises questions about 239 similar open-air experiments conducted by the Army in the twenty years between 1949 and 1969.

Telecommunications for Third World: The use of new technology to provide reliable telecommunications for remote rural areas in Third World countries was one of the few practical suggestions to be made at the recent UNCSTD meeting in Vienna. Already worked out in considerable detail and coordinated by the International Telecommunications Union in Geneva, the proposed Global Domestic Satellite System aims to make use of the increasing reliability and convenience of geostationary satellites (types such as INTELSAT 5 and SYNCOM 4 were referred to in the paper) as the central transmission facility. Such a satellite would transmit to transistorised ground stations operable on a 12-volt battery pack costing an estimated $ US 15,000. Retransmission would be by line of sight radio to the surrounding area. ITU believe that the rapid growth and refinement of the techology involved indicates the feasibility of launchings in 1982/3.

India to train Vietnamese scientists: India will train scientists from Socialist Republic of Vietnam under a programme of science and technology co-operation signed in New Delhi in July. The training will be in survey techniques, railway technology, information sciences, water resource management and research in drugs and medicinal plants. Areas of further co-operation between the two countries, in the fields of water management, pollution control, highway engineering research, traditional herbal remedies and medicinal plants will be explored by Indian scientists who will be sent to Vietnam. The programme is follow-up action of an agreement on cooperation between the two countries signed in Vietnam earlier. *Zaka Imam, New Delhi.*

Thai researchers go for mushrooms, not poppies: The Thailand Institute of Scientific and Technological Research, Bangkok, has been investigating the cultivation of the button mushroom on paddy straw, one of the major agricultural wastes of the country. It is hoped that it will be suitable for cultivation by the poor hill tribes of North Thailand — where the opium poppy presently provides much income.

Why Britain does not need a Minister for Science

By Margaret Thatcher

Ian Lloyd, a Conservative MP, was the chairman of the sub-committee on science of the Commons Select Committee on Science and Technology. We publish excerpts from an exchange between him and Margaret Thatcher on science policy

Sorry about the Select Committee

‘**Dear Prime Minister,** I hope you will not mind my sending you two documents which bear on the exchange of views on science policy administration between us at Question Time on Thursday 12 July. The first is an article by Judy Redfearn in *Nature* (12 July, 98-99) on the role now being filled by Pierre Aigrain in France. The second is a guest leader in *New Scientist* which I have been asked to write (2 August, 346).

Pierre Aigrain was Chairman of the Committee on Information Technology in the EEC which now bears his name. He has made a distingushed and forceful contribution to science policy. The role which he now discharges in the French government is precisely what I had in mind when putting my question. Apart from yourself, no Minister, to my knowledge, has the same function here. There is no national "science budget", only a series of departmental science budgets . . . There is, therefore, no overall view and such a view is urgently required.

Aigrain has commissioned and is publishing a report on the organisation of French science and the resource allocation policy behind it which he claims, I believe rightly, to be unique. I do not know of any report which is as comprehensive as "L'état des sciences et des techniques francaises" and I am not aware of any document in the UK which provides information from which government, or anyone else interested in science policy, could draw conclusions similar to those set out in the inset article on page 99 of *Nature*.

I hold a strong conviction that we need such a Minister, such an allocation of responsibility, and that a similar report on the organisation and effectiveness of scientific research within the UK is required. I do not believe that a general sympathy for the importance of science and technology within the existing departmental structure — important though it may be — is a sufficient condition for the successful appliciation of science in the United Kingdom in today's circumstances . . .

My other reason for raising this issue is the profound dismay which I believe we have caused by a failure to re-establish the Select Committee on Science and Technology. I know that the Parliamentary and Scientific Committee is most concerned about this and that this lies behind the decision of the House of Lords to set up their own Select Committee on Science and Technology which they hope eventually to broaden into a joint committee of both Houses. While this is no substitute for the Commons committee, it will salvage something from the wreck and I strongly support their Lordship's initiative. Their contribution of scientific expertise will be most important and it is conceivable that such a joint committee, provided it has the government's suport, may well develop into an organisation around which a thorough and wide ranging review of national policy and performance in the field of science and technology policy might be built . . . ’

‘**Dear Ian,** You will remember that your point was extensively debated here in the early 1970s. In fact there was then a more centralised science budget than there is now . . . But the centralised system was not considered satisfactory.

Our system was given its present shape by the 1972 White Paper "Framework for Government Research and Development" (Cmnd 5046). . . These arrangements were reviewed by the last Government. The result of the review was published in March this year as a White Paper (Cmnd 7499).

Our system recognised that Government-sponsored applied science and technology is not an end in itself, but a means of helping to achieve the Government's policies and objectives. It follows that policy on applied science and technology in any sector should be associated with policy on investment, human resources, market needs and other factors, and should therefore be the concern of the Minister responsible for overall policy in that sector. But there is one sector — fundamental research — where there is no close link between research and policy. For that, it makes sense to entrust responsibility to the Minister who is responsible for those institutions of higher education where much of this type of research is done . . .

If we went over to a centralised system with a separate Minister for Science with his own department we would have to accept the disadvantage of divorcing those responsible for applied R and D from those concerned with formulating and implementing the policies to which their R and D related. In fundamental science we would have an unwelcome division between responsibility for higher education and for the scientific community supported by the Research Councils.

At present we have machinery to ensure that there is no harmful overlap between Departmental R and D programmes and policies, that no gaps arise, that policy questions with a major scientific or technological content are considered inderpartmentally; where this is necessary and that the quality and direction of R and D in any area, or over all areas, can be assessed. Since 1976 a committee of permanent secretaries and chief scientists has provided interdepartmental coordination of science and technology matters at high official level; and the Central Policy Review Staff play an active part in the overview aspect . . . .

I note your view that we need for Britain a report on the organisation of our science and the resources that go into it on the lines of what the French are doing. I should like to consider in due course whether such a report would be valuable . . . . The Research Councils and several Departments publish annual reports on the R and D, and it may take some time to digest the implications of the reduction in public expenditure to which we are committed. But I am quite sure that we do not need a Minister for Science to prepare such a report . . .

I am not saying that our present system should never be adapted. On the contrary, I intend to keep an eye on how it is and modify it as may be required. I recognised, for example, that under the present arrangements issues may arise which straddle the responsibility of several Ministers to such an extent that it would not be sensible to ask one of them to take the lead. In such a case I would myself play a coordinating role . . .

Personally I was very sorry that the House decided not to re-establish the former Select Committee on Science and Technology. I thought it did valuable work and was complementary to the role of departments. But you and I were overruled by the vote — however much we both regret it. ’

From begging bowl to bread basket

In his final report on science in India, Anil Agarwal describes the green revolution that has put India in the position of being able to feed its starving millions. But only in principle . . .

In 1967, William and Paul Paddock wrote a book called "Famine 1975 — America's Decision: Who Will Survive?" In this book, the Paddock brothers classified developing countries, based on their population growth rates and potential to grow food, into three categories: 'can't be saved', 'walking wounded' and 'should receive food'. India suffered the ignominy of not only being classified as 'can't be saved' but also of being accredited with the comment that it "is the bellwether that shows the path which the others, like sheep going to slaughter, are following." India was thus a country, according to these authors, to which the US should not have bothered either to provide aid or food.

It is therefore almost with glee that Dr M.S. Swaminathan, the former Director-General of the Indian Council of Agricultural Research (ICAR), seems to have quoted these statements of the Paddock brothers in his lecture to the Administrative Staff College of India at Hyderabad now entitled: "From Begging Bowl to Bread Basket". For indeed, as seen in 1979, the genetic package that India adopted in the late 1960s in the name of the green revolution, is now increasingly turning it into a major, and hopefully stable, producer of cereals. India has had bumper harvests for the last four years (1975-79). In 1978-79, the grain output touched a high of 126 million tonnes, culminating in a record government-held grain reserve of 26 million tonnes, which is more than half the total import of foodgrains by the Third World in 1975.

India has recently supplied several countries like Afghanistan, Bangladesh, Viet-Nam and USSR with food shipments and, at one point, even Pakistan, was reported to be considering a request to India for grain. A special committee appointed by the government recently recommended that India should start planning grain and vegetable exports on a regular basis to develop stable markets, though initially, it said, the grain exports could be kept at a low level of 1 million tonne a year. Some Indians still remain cautions about rushing into a venture that may not be possible to sustain. Many indeed find it difficult to believe that India can become a grain exporter. Without any doubt, the succession of good weather for four years has largely been responsible for the bumper harvests, and India's climatic pattern shows that after every 3-4 years of good weather, there is a recurrence of 1-2 years of serious drought. But, simultaneously, a feeling is growing that with the spread of irrigation, fertiliser use and high acreage under high yielding varieties (HYVs), the increases in agricultural output that India has been witnessing, are of a permanent nature.

In fact, the time when this belief will be tested is already here. Northern India is currently witnessing, according to some meterological reports, its longest dry spell since 1906. The Chief Minister of the populous northern state of Uttar Pradesh recently claimed that Rs 7000 million worth of agricultural output has been destroyed in his state alone. But Dr Swaminathan, now the Agriculture Secretary, claimed at a press conference that the fall in India's total production will certainly not be as precipitous as it used to be after drought years in the past. And, furthermore, he pointed out that the problem in 1979 is not one of grain scarcity, but one of organising efficient distribution of grains and launching crash food-for-work programmes so that the rural poor, whose crop has been destroyed, can get employment.

Even outside India, several organisations are waking up to the agricultural potential of India. The World Bank, in its annual report for 1979, released this week, claims that there are growing indications that the 'floor level' of India's grain output has been raised. James Grant, President of the Overseas Development Council, Washington, even believes that India is fast acquiring the potential not only to feed itself but also countries outside. Crop yields in India are still very low. Its acreage is very large. This gives India an enormous 'untapped yield reservoir', as agricultural scientists call it.

How to triple output of grain

In an article published in a book entitled Mobilising Technology for Development, released last month at the UNCSTD, Grant explains: "Yields per acre in India (particularly of rice, which has the largest acreage) are aproximately 1,000 pounds, compared to 3000-4000 pounds in the more advanced countries (including even Third World countries like Taiwan and South Korea). India has about the same overall quality of natural environment — land, water resources, temperature, *etc.* — as the United States; it also has roughly the same arable acreage. Twenty per cent of its land is under irrigation (in comparison to 10% in the US), and this could easily be doubled in the 1980s — at a time when worldwide additions to irrigated acreage are expected to slow sharply as compared to the past 25 years.

"India, therefore, could be producing at least three times more grain per acre than it is now doing, at present cost levels, if it could overcome certain problems of organisation, finance, and applied research. This would increase its total output from the current level of 120 million tons of grain to more than 300 million tons (compared to a present US level of 250-260 million tons)."

Indian should actually attempt to do so, argues Grant, because there is the growing need for an alternate breadbasket for the world. The International Food Policy Research Institute, Washington, has estimated that the Third World's food imports will triple to about 120-145 million tonnes every year by 1990, and this may be beyond North America's capacity to supply alone.

The success that has been achieved already is to a great extent the result of investments made in agricultural research. The ICAR was set up in 1929 by the British colonial government — but nobody even knew in 1964 "where the ICAR was in the organisation chart of the government", to quote a senior Indian science planner. It was then a small 'attached office' in the Ministry of Agriculture, totally bureaucratised and emaciated. But in that year, the ICAR was reorganised as part of the country's drive towards the green revolution, and expenditure on agricultural research by ICAR rapidly grew from Rs 64 million in 1965-66 to Rs 370 million in 1976-77 (though still less than the amounts spent on either defence, atomic energy or space research). Research is now conducted through a grid of agricultural universities, 29 central research institutes and numerous all-India coordinated research projects sponsored by the ICAR.

Indian agricultural scientists have received considerable support in their work from international institutes like the International Maize and Wheat Improvement Center in Mexico and the International Rice Research Institute in the Philippines, but they themselves have conducted substantial research to adapt imported genetic material to local environmental conditions, find new high yielding varieties (HYVs), and develop the agricultural practises required to support them. International agricultural R&D centres have now multipled to eleven, but recognising that they cannot take the role that national research organiations should play, as shown by the work of ICAR, the Consultative Group on International Agricultural Research will set up a new institution called the International Service for National Agricultural Research (ISNAR) in 1980. ISNAR will mainly help to develop national crop research centres.

But successes notwithstanding, Indian agricultural research faces even stronger challenges in the years ahead. It is important, for instance, to develop more biological sources of nitrogen fixation like blue-green algae, which reduce the need for

Joseph Hanlon

Increasing rice production by for a second crop

expensive chemical imputs. Without this type of new agricultural technology, most small and marginal farmers will remain seriously constrained in using the green revolution technology package. A large part of the increase that has taken place in rice production in recent years has been contributed by the rich farmers of Punjab, which is not a traditional rice-growing state. During 1978, the government procured more rice from Punjab alone than in the whole of the rest of India. Punjab's rice yields are more than double the all-India average yield. Rich Punjab farmers were also the forerunners of the green revolution in wheat. Punjab produced more wheat in 1978-79 than was produced in all India 1951-52. Eastern India, however, which is the traditional rice-growing region, has not benefitted equally from the new genetic package in rice. This region is dominated by extremely small landholdings and prone to floods, which submerges the short HYVs.

Major research into pest control

Pest and disease control is another major area of research. The danger of pest and disease invasion is much higher in tropical regions and HYVs have not only been, in general, found to be more susceptible compared to the traditional varieties, but their introduction has resulted in some minor pests, like the brown plant hopper, emerging as major threats. Integrated pest control and surveillance practices which reduce or obviate the need for pesticides will, therefore, have to be developed.

Protecting the "ecological infrastructure", as Dr Swaminathan puts it, is yet another area for careful research and planning. Intensification of agriculture and increased pressure on forests for domestic fuel and commercial timber, particularly in the Himalayas, is now resulting in serious floods year after year. Environmentally sound agriculture and forest managemnt in mountainous ecosystems is, therefore, of prime importance to India. But substantial research has yet to be done in this area and, even more work has to be done to introduce what is known to the local people.

Equally important is the question of soil fertility. Burning of cowdung and lack of tradition for using human excreta as manure means that organic fertilisers are not reaching the soil. In certain heavily cultivated northern states, research is now showing that even certain micronutrients like zinc are becoming constraints to increases in yields which can only be partially offset by the increased use of nitrogenous chemical fertilisers.

Research in non-cereal food also needs considerable attention. Pulses, which provide most of the protein in the Indian diet, have suffered a setback in production as farmers have increasingly turned away from pulses to grow the more remunerative HYVs of important cereals in the wake of the green revolution. Until HYVs of pulses are also available, farmers are unlikely to give them high priority. The India-based International Crops Research Institute for the Semi Arid Tropics is now actively conducting research on certain pulses. But several other minor crops that are locally important, for instance, in the hills, continue to be under-researched.

Conservation of germplasm too is a vital area. India is a rich centre for genetic variability in several important cereals, vegetables, cotton, pulses and fruit trees. With increasing deforestation and cultivation of monocultures spreading rapidly, this genetic treasurehouse stands threatened. Organisation of germplasm banks is thus of extreme importance.

Some good progress has certainly been made in research on dryland farming, largely aimed at reducing risks in cultivation in rainfed areas. Even with full untilisation of available water in the Indian subcontinent, there will be large areas that will not be able to receive assured irrigation. Even small fluctuations in the monsoon often spell disaster for farmers in rainfed areas and agriculturists in such areas are usually very poor. The ICAR has been doing extensive research in this field. It hopes eventually to provide farmers there with the option of switching over quickly to an alternate crop that can be grown in the remaining period of the crop season. This would ensure the farmer some return at least in that year.

Crop life-saving research, which aims at saving the plant in periods of acute stress, has also been showing good results, The integral part of such research is water management at the level of every watershed. Each watershed is advised to make a pond to collect the run-off and use this water to save the crop. Essentially, this is not a new advice. Most villages in ancient India have a village pond. Together with this engineering approach, efforts are also being made to develop new drought-resistant HYVs.

Vicious effects

The future of agricultural research in India is thus both bright and challenging. But whether all Indians will benefit from it equally is something that will depend much on India's social and political will. The green revolution technology has had a vicious effect on the rural poor. But to what extent the new agricultural technology is responsible for it, is not yet clear. In a highly stratified socioeconomic environment, it is more likely that any new technology which offers major productive oportunities, will be used by the more powerful to become still more powerful.

This is true, in fact, of even the age-old technology of irrigation. "Few people seem to realise that, normally, in the case of any irrigation scheme, out of every rupee worth of direct benefits accruing from irrigation, 54 paise would go to the large and big farmers who account for only 10 per cent of the total rural households", says a report recently prepared by a senior official in the Ministry of Agriculture.

Agricultural science, however, has clearly shown that it has the potential to feed India's population, and given political will and mobilisation of the people, even provide employment on a massive scale. But will the agricultural scientists get full support in their venture? It is interesting to note that after the Pokhran nuclear explosion in 1974, the government of India had quickly announced that nearly half a dozen nuclear scientists would get the Padma Shri, India's national award. But few scientists were so honoured for their work on HYVs of wheat, which changed India's agricultural future. □

Berufsverbot: physics professor sacked

SIR, Professor Jens Scheer, one of the leading critics of Germany's nuclear energy program, is to be forced to leave his life-long tenured position as professor of nuclear physics at the University of Bremen. The Administrative Court of the Free Hanse City of Bremen imposed this sentance of Berufsverbot (profession forbidden) in June after a disciplinary trial and retrial lasting two years. In its ruling the three-judge panel concluded: "As an appropriate disciplinary action for this offence only the heaviest one can be considered: expulsion from office".

The "offence" appears in the Federal Constitutional Law for Civil Servants. It is only because the German civil service includes, *inter alia*, permanent university staff that professorScheer is bound by this law. This circumstance has important and unavoidable consequences especially for those who must teach and carry out objective research. The court stated:

"It is expected of a civil servant that he recognises and acknowledges the State and its constitution as a high postitive value worthwhile to defend actively; Federal Constitutional Law (Beschluss von 22,5, NJW 1975, 1641)". (This is applied to one's private life as well.) "According to this law (Art. 33 Abs. 466) a civil servant stands in public-legal relations of service and loyalty. That is why it is his duty to be loyal toward the State and the constitution (political loyalty-duty of the civil servant)."

The ideal of this law has been recurrently expressed in the last century of German History as a means to bring academics under the political scrutiny of the State authority. The present authorities have not changed history.

The nature of the trials of Professor Scheer is typical of the political trials going on in Germany today on a large scale. This latest Berufsverbot trial against him was based solely political principles and membership in the KPD (Communist Party of Germany) which is a legal party. The court noted that he "prominently", "publicly" and "actively" agreed with the principles of the party (i.e. he had recently stood as a local and parliamentary candidate and had sold the party newspaper). These were the only accusations used for the conviction and sentence. He was not allowed a complete defence.

Banning may come to those not quite bound by the golden chain of civil servant status, without court proceedings, after an investigation by the secret Federal Constitution Protection Police (BVSP) or because of accusations collected from paid informants of from fellow-teachers and pupils.

Over the past five years the authorities have brought at least seven prosecutions against Professor Scheer, one after the other. Since all these attempts failed, the authorities came eventually to rely on exclusively political accusations.

The present trials is in fact one of a series of Berufsverbot trials, where new charges have constantly been laid. The trials began before Professor Scheer became politically 'prominent'.

People who support Professor Scheer or who are terrified by the existence once again of these laws are asking the Senate of Bremen to overturn the court's ruling. These people include the Rector of the University, at least three-quarters of the professors, a similar majority of the University Staff Assembly and many students.

There is no doubt "that the West German authorities disregard individual rights and use improper methods in order to silence their critics". There is no doubt that the Civil Servants Law and its reflection in Bremen are tools to that end. And there is no doubt that neither truth nor democracy can proceed on the basis of loyalty, discipline and obedience.

Yours faithfully,

UWE LAHL
W THIEMANN

University of Bremen

Indian science

SIR, "India: the struggle for useful science" by Anil Agarwal (23 August p 625) was objective — but gave very little account of the role of scientists in general. Though India boasts a large reservoir of talented and well-trained scientists, unemployment and under-employment among scientists are considerable. Many talented scientists fail to make any mark because of their inabilities to go along with the establishment. And when these scientists go abroad to prove their abilities, the establishment itself honours them. At least three Indian scientists have committed suicide out of sheer frustration in not being able to cope with the powers that be. Although everybody appreciates the role of science, no one has yet given any serious thought to the exact role and ambition of scientists in the research and developmental projects of which he is considered to be a part. Research institutions are mostly modelled on a bureaucratic pattern and, as correctly pointed out in the article, unless one turns into an administrator, a professional scientist is rarely honoured. Fortunately, there is no restriction as yet to free expression by scientists: hence this letter.

Yours faithfully,

B BANERJEE

Tocklai Experimental Station, Jorhat

Humane farming

SIR, Baker and Manwell (23 August, p630) strongly infer that I oppose "humane" treatment of farm animals by advocating intensive husbandry. This is incorrect. I am not an animal behaviourist, but I have supervised the rearing of farm animals in confinement, under experimental conditions, for many years. There are, broadly speaking, two approaches to humane treatment, pragmatic and anthropomorphic. The pragmatic approach says that inhumane treatment is counter-productive, because unhappy animals do not eat well, and hence do not thrive. Solitary confinement shows this. Chickens search frantically for a companion. In one instance, two cows would not eat when separated, but started again when a window was cut in the partition. However, companionship may be *de trop*; egg production in hens is diminished by sexual harassment by male chauvinist roosters, which are therefore kept away, except in breeding flocks.

The floor space per animal allotted under confined conditions must be adjusted for maximum productivity, which is diminished by overcrowding. Composition and intake of food must be nutritionally optimal, drinking water always available, and ambient temperature such as to be compatible with good health. Dairy cows are notoriously sensitive, not to intensive husbandry, but to minor annoyances, which may make them refuse to let their milk down.

The anthropomorphic approach that decries crowding of farm animals is of dubious validity, in view of the fact tht human beings pay large sums to be jammed together at football games and in theatres. The most successful cocktail parties are tightly packed gatherings where the noise is deafening, and hotels in the United States display signs that warn against over-occupancy of meeting rooms. The chicken that has to roam in the out-of-doors probably would choose the protection of the hen-house against foxes, coyotes and *Accipiter* hawks.

Indeed, with rare exceptions, such as myself, wilderness conservationists dislike the solitude of the wilderness, for I have noted that most devotees of the Sierra Nevada seek out the few crowded areas, such as the John Muir Trail and the summit of Mount Whitney, leaving the choicer spots to darkness and to me.

Yours faithfully,

THOMAS H JUKES

Berkeley, California

Costs of toxicity testing

SIR, Dr Conning in his letter of 2 August (p 354) draws attention to the problems facing the chemical industry worldwide, of society demanding greater assurance against the risks of error or of inadequate knowledge than it did in the past. One of the principal difficulties has been to anticipate the possible effects of a chemical on man and the environment before it was introduced into commerce, expecially in those cases where the effect may become apparent only after a long latent period.

In a Discussion Document published in June 1977, the Health and Safety Commission proposed to require by statutory regulation the formal prior study and reporting of the toxic properties of substances which were to be newly introduced. This was an attempt to establish a first order of priorities, since although — as Dr Conning rightly points out — even long experience of manufacture and use does not provide an infallible safeguard, at least by tackling urgently the 'new' substances we should not be adding to the existing list of 'don't knows'. HSE does not intend to produce guidelines on how to test chemicals, but merely to indicate what data would be needed as basic information for an evaluation of the properties of such substances.

It is common ground in this field that what we need are properly validated test procedures whereby chemicals may be screened effectively and at minimum cost in order to identify the hazards which they might present in manufacture and use. Such procedures must, however, be kept flexible in order not to dissipate resources in needless evaluation of effects which could be assessed from existing data either published or held in firms' archives.

Yours faithfully,

E W LANGLEY

Joining immunoglobulin genes

from W. Dunnick

ONE classical idea in immunology is the joining of variable region genes to constant region genes. The carboxy terminal part (constant, or C region) of immunoglobulin polypeptides is sequence invariant, and is probably coded by one or a few genes. For example, 95% of all mouse light chains have a single 'kappa' C region sequence; the remaining 5% are divided between two 'lambda' C region sequences. These protein sequences are probably encoded by a single kappa C gene and two lambda C genes. The amino terminal part (variable, or V region) of immunoglobulins is highly diverse in sequence; duplicate V sequences are rare among the hundred or so mouse kappa proteins studied to date. Fifty to one thousand genes are thought to code for mouse kappa V regions. Dreyer and Bennett proposed that the immunoglobulin 'gene' is formed from these two different gene pools by translocation of DNA (*Proc. natn. Acad. Sci. U.S.A.* **54**, 864; 1965). Thus, one V gene (out of hundreds) is joined to one C gene to form the genetic unit which is transcribed and translated.

This idea was proved correct by restriction analysis of DNA (Hozumi & Tonegawa *Proc. natn. Acad. Sci. U.S.A.* **73**, 3628; 1976), and by cloning and sequencing experiments (Bernard, Hozumi & Tonegawa *Cell* **15**, 1133; 1978). Immunologists were surprised to learn that, in the germline, the last one-eighth of the V region was not attached to the rest of the V region (where it belonged), but was closely associated with the C gene. In embryonic DNA, the DNA segment coding for the first 95 amino acids of the lambda V region was separated, by more than 4.5 kb, from the segment of DNA which included the coding sequence for the last 13 amino acids of the lambda V region (the J segment), the coding sequence for the lambda C region, and the 1,200 bp intervening sequence between J and C. In DNA of a cell producing a lambda light chain, the V segment coding amino acids 1–95 is joined to the J segment coding for amino acids 96–108 to form the contiguous V gene. The intervening sequence remaining between V and C is probably removed by RNA splicing (see *News and Views* **276**, 322; 1978, for more background and references). In the mouse, the kappa light chain system is more complicated than the lambda system; there are about 100 times more kappa V segments than lambda V segments. The analysis of kappa J segments by Max *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **76**, 3450; 1979) and by Sakano *et al.* (*Nature* **280**, 288; 1979) has revealed a system slightly more complicated than the single lambda J segment, but also more informative.

Both groups cloned a segment of embryonic DNA that included the kappa C gene and 4.5 kb upstream from the C gene. A large part of the DNA was sequenced, and five J segments were identified by homology to kappa protein sequences. The J segments are in a cluster, separated from each other by about 300 bp; the nearest to the C gene is about 2.5 kb away (Fig. 1). In the 5′ direction, there are no additional J segments within 1.1 kb; there are probably none between J5 and the kappa C gene. The data cannot exclude additional J segments elsewhere. From other data it seems unlikely, though not impossible, that additional kappa J segments exist.

J segments and joining

What recognition signals are important in V–J joining? Adjacent to the 3′ end of sequenced V coding segments and to the 5′ end of each of the five J segments is the palindromic sequence (or a slight variant of) C–A–C($^{A}_{T}$)G–T–G. This sequence is also found following a lambda V segment and before the lambda J segment (Bernard *et al. op. cit.*). A second consensus sequence is found 25–30 nucleotides from the J segments, G–G–T–T–T–T–T–G–T–A. The homology is so striking and well-preserved that one feels the presumptive joining enzyme would recognise these sequences. Using the cloned V and J segments, one might begin a search for the joining enzyme. This could be a formidable task, as no one knows in what cells V–J joining takes place, or how many of these cells can be isolated.

Of the five J segments, examples of four can be found in known kappa protein sequences. The J3 sequence is not found in any known protein. It has the most divergent sequence of the set, and the intervening sequence following J3 does not begin with G–T, even though almost all other intervening sequences do (Breathnach *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4853; 1978). Thus, Max *et al.*

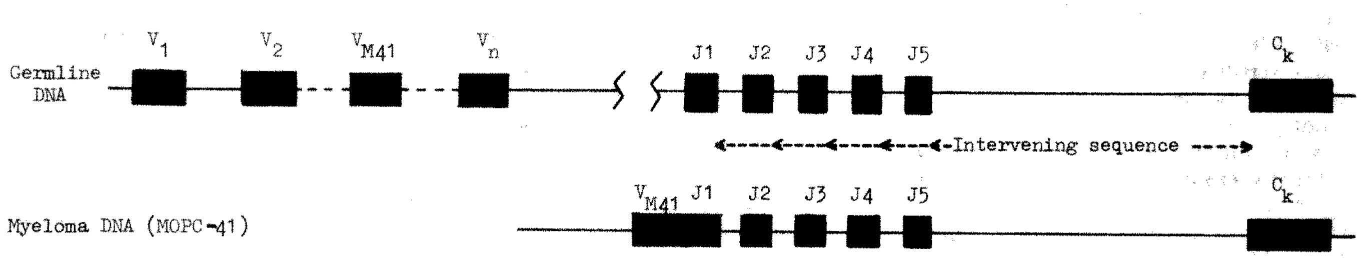

Fig. 1 Arrangement of kappa light chain genes in germline and myeloma DNA. Adapted from Seidman *et al.* (*Nature* **280**, 370; 1979). This figure is not drawn to scale. Darkened boxes are coding sequences. The exact arrangement of the V segments is not known, relative to other kappa V segments or to the kappa J segment and C gene.

0028-0836/79/390253-01$01.00

suggest that J3 is not expressed in protein because its intervening sequence cannot be properly excised. The correlation between expression and junction sequence is interesting, but there is a second exception to the G–T rule which is certainly excised properly and expressed (Sakano *et al.* *Nature* **277**, 627; 1979). How rigid is the G–T rule? In the J3 segment, is divergence away from G–T at the beginning of the intervening sequence a cause for non-expression or a result of non-expression?

J segments and diversity

Both Max *et al.* and Sakano *et al.* have noted that V–J joining may generate sequence diversity. Bernard *et al.* (*op. cit.*) and Weigert *et al.* (*Nature* **276**, 785; 1978) have also suggested the possibility. By adjusting the point of recombination within the three nucleotides following the V coding sequence and the three nucleotides of residue 96 in the five J segments, one can generate all known residue 96 amino acids in Balb/c and NZB kappa proteins. As an example, the nucleotide sequence at the end of the MOPC-41 V segment is (Seidman *et al.* *Nature*, **280**, 370; 1979):

Pro 95| non-coding DNA
-C -C -T -C -C -C -

The first three nucleotides of J1 are -T–G–G–. Recombination joining the first C after the V coding segment to the two Gs in the J1 segment yields -C–G–G–. C–G–G codes for arginine, residue 96 in MOPC-173 (residues 97-108 of the MOPC-173 kappa chain are consistent with the sequences of J1). Other possible results of recombination are -C–C–C- (Pro, MOPC-11), -C–C–G- (Pro, MOPC-11), and -T–G–G-(Trp, MOPC-41). Another possible event joins the three Cs following the V segment to the three nucleotides coding for residue 96 in the J segment. For example, joining -C–C–C- following the MOPC-41 V segment to -T–A–C- at the beginning of J2 yields Pro–Tyr, the residues 96 and 96a of 7132, a NZB kappa chain which has an 'extra' J amino acid.

Does sequence diversity at residue 96 lead to new antigen combining sites? This question, though central to discussions of diversity, is difficult to answer. In the few immunoglobulins whose three-dimensional structure is known, amino acid 96 is near or at the antigen combining site (Padlan *et al.* *Immunochemistry* **13**, 945; 1976). It is probably safe to assume that diversity generated by V–J joining, in some cases at least, can alter the antigen binding properties of immunoglobulins.

V–J joining is an exciting topic because it is the first example of a defined molecular mechanism which probably leads to V region sequence diversity. This is a step forward for immunology. Nevertheless, V region diversity must also be generated by other mechanisms. None of the sequence differences in mouse lambda V regions can be explained by V–J joining. In mouse kappa V regions, 20–30 amino acid residues show more sequence variability than does residue 96. The light chain of myeloma-2413 (from a NZB mouse) has aspartic acid at residue 103 and glutamic acid at 107. Both residues are lysines in all five Balb/c germline J segments. Either the NZB has at least one different J segment, or somatic mutation must act even on J segments.

From work during the past three years, culminating in the papers by Sakano, Max and their colleagues, we know a great deal about light chain J segments in the mouse genome. Protein sequence data suggests that heavy chains also have J segments (Rao *et al.* *Proc. natn. Acad. Sci. U.S.A.* **76**, 2890; 1979), and recombination has been postulated to occur near residues 96–104 in human kappa chains (Milstein *Nature* **216**, 330; 1967). Several questions concerning J segments will be answered by studies in these areas. How many J segments do the kappa and lambda systems have in humans, where the two light chains are about equally represented in serum immunoglobulin? Does each heavy chain C gene have its own J cluster? Does the role of J segments in diversity extend beyond V–J recombinations? □

Sun shines on photosynthetic prokaryotes

from A. J. Smith

THE clear message to emerge from recent studies with photosynthetic prokaryotes is that there is much more to the microbial world than *Escherichia coli.* Of particular interest is the application of recombinant DNA techniques to the analysis of the genetics of these organisms. At a recent symposium* B. Marrs (Saint Louis University, Missouri) described how a promiscuous plasmid with sex factor activity has been used to mobilise segments of the chromosome of *Rhodopseudomonas capsulata* including that carrying the genes for photopigment synthesis, reaction centres and tryptophan synthetase. The cloning of portions of this DNA for use in studies of gene structure, function and regulation is now possible following the isolation of R-prime plasmids in which the photopigment genes are incorporated into the plasmid structure. The genetic analysis of cyanobacteria has been handicapped by difficulties in the isolation of mutants and the lack of efficient systems for gene transfer other than transformation which has been demonstrated in a number of strains. R. Haselkorn (University of Chicago) has avoided these problems in an investigation of the genes for nitrogen fixation (*nif* genes) in an *Anabaena* sp. He identified fragments of cyanobacterial DNA containing *nif* genes by hybridisation with recombinant plasmids containing defined segments of the *nif* region of *Klebsiella* DNA and found a 10 kb fragment which contained sequences complementary to *Klebsiella* genes *D*, *H* and *V* (genes *D* and *H* code for components of nitrogenase). Sequences complementary to genes *Q*, *B*, *A*, *F*, *M* or *S* were not found in any of the DNA fragments, suggesting that the *Anabaena* counterparts of these genes have diverged too far to be studied by this technique. The discovery of closed covalent circular DNA (plasmids) in a variety of cyanobacteria (G. A. van Arkel, State University, Utrecht; F. Doolittle, Dalhousie University, Halifax, Nova Scotia; V. Saunders, Liverpool Polytechnic), has introduced the possibility of using them to mobilise sections of the chromosome of these organisms. The Utrecht group reported the successful incorporation of an ampicillin-resistance marker of the *E. coli* plasmid pR146 into a small 53,000 molecular weight plasmid in *Anacystis nidulans* R-2. In the gene transfer system they are currently developing, this modified plasmid will be used as the cloning vehicle for fragments of chromosomal DNA by the technique of insertional inactivation. This insertion of the complete sequence of the Tn*901* transposon into the cyanobacterial plasmid along with the ampicillin resistance marker may yield a new method for producing mutants if the jumping character of the DNA segment is preserved in its new location. These recent advances will open the way for analyses of genes specifying the photosynthetic apparatus, nitrogen fixation and the mechanisms for their regulation as well as the characterisation of processes governing the development and differentiation of photosynthetic prokaryotes.

Photosynthetic bacteria and cyanobacteria include organisms which are being used as model systems for the study of morphogenesis and differentiation as indicated by the review papers on *Rhodomicrobium vannielii* (C. Dow, University of Warwick) and cyanobacteria (C. P. Wolk, Michigan State University). Factors determining the production and spacing of heterocysts, which are the sites of nitrogen fixation in certain filamentous cyanobacteria, have yet to be fully characterised. Furthermore, the identity of the reductant that passes from vegetative cells to the heterocyst to support nitrogen fixation and the origin of glutamic acid which is used to export combined nitrogen in the opposite direction have yet to be established with certainty. Reports of reproducible procedures for the production and germination of akinetes (M.

*The Third International Symposium on Photosynthetic Prokaryotes was held on 27-31 August in Oxford and was organised by N. G. Carr (University of Liverpool.)

0028-0836/79/390254-02$01.00

Herdman, Dundee University) which are a form of non-growing resistant cyanobacterial cell indicate that the analysis of this further example of prokaryote differentiation is now possible.

Recent work on pigment organisation and primary photochemistry which was reviewed by P. Thornber (University of California, Los Angeles) highlighted the specialised features in some photosynthetic prokaryotes of the antenna complexes which harvest light energy and channel it into the photosynthetic reaction centres. Chlorosomes (formerly known as *Chlorobium* vesicles) which fulfill this function in green photosynthetic bacteria consist of a relatively unorganised assemblage of bacteriochlorophyll *c* molecules in a non-unit membrane-bound sack positioned in close proximity to bacteriochlorophyll *a* – protein complexes in the cytoplasmic membrane. The antenna complexes of cyanobacteria and red algae are known as phycobilisomes. D. Bryant (Pasteur Institute, Paris) proposed that these highly organised complexes of several types of phycobiliprotein consist of a triangular core of allophycocyanin molecules with three peripheral rods radiating from each of two sides of the triangular core, the rods being made up of phycocyanin and of phycoerythrin. The sharing of certain carriers between photosynthetic and respiratory electron transport which has been demonstrated in photosynthetic bacteria may prove to be a feature of cyanobacteria as well; the dark aerobic utilisation of molecular hydrogen by *Anabaena cylindrica* is likely to involve the transport of electrons along the section of the carrier chain containing plastocyanin and plastoquinone (H. Bothe, University of Cologne).

The factors that play a critical part in establishing the dominance, albeit transient in some cases, of natural populations of photosynthetic prokaryotes are ill defined. Recent field and laboratory studies have introduced the real possibility of interpreting ecological phenomena in terms of the physiology and biochemistry of photosynthetic prokaryotes. H. van Gemerden (University of Groningen) proposed that the availability of acetate is a factor likely to contribute to the appearance of blooms of *Chlorobium phaeobacteroides* in Lake Kinneret. Other reports attributed the survival of a large population of the cyanobacterium *Oscillatoria limnetica* in the 'solar lake' in Israel despite extreme and rapid fluctuations in conditions to the metabolic flexibility of this organism. Besides the ability to switch from anoxygenic to oxygenic photosynthesis (B. B. Jorgensen, Hebrew University, Jerusalem), this organism is also able to catabolise endogenous polysaccharide reserves either by an aerobic respiratory mechanism or by a lactate yielding fermentation under anerobic conditions (M. Shilo, Hebrew University, Jerusalem).

In the session on evolution R. E. Dickerson (California Institute of Technology, Pasadena) maintained a lively hope that protein sequence studies would, in due time, yield data of phylogenetic significance, the accumulation of new information serving to minimise the blurring effect of lateral gene transfer. This final session closed with a progress report delivered in inimitable style by R. Lewin (La Jolla, California) on the characterisation of prochlorophytes which are associated with colonies of didemnid ascidians. Their seemingly opposed affinities on the one hand to bacteria in terms of ultrastructure and on the other to green algae in terms of their photosynthetic apparatus has been further confirmed by work in various laboratories. The outstanding requirement here is for conditions to be identified which will transform these ecological eccentrics into creatures amenable to laboratory investigation. □

Photosynthesis research in the USSR

from D. O. Hall

In the USSR a massive effort is being put into photosynthesis research in all its various aspects. To improve crop yields, physiological and agronomic aspects must be understood; if biomass is to be used as a source of energy photosynthetic efficiencies must be improved; and if photosynthesis is ever to be mimicked to provide 'futuristic' energy, for example hydrogen and fixed carbon and nitrogen, the basic processes of photosynthesis must be understood. All these aspects of research into photosynthetic mechanisms are being undertaken in the USSR in a seemingly determined way.

A travel exchange between the Royal Society and the USSR Academy of Sciences recently enabled me to visit three centres of photosynthesis research — the Moscow-Pushchino region in Russia, Tashkent in Uzbekistan, and Kiev in the Ukraine, all of whose research has some relevance to solar energy utilisation. The huge Biological Centre at Pushchino incorporates the Institute of Photosynthesis, which to my knowledge is the only such Institute in the world devoted solely to the study of photosynthesis. A new young director Y. E. Erokhin was recently appointed and has responsibility for several hundred research workers and technicians in the departmental groupings — photochemistry, biochemistry, molecular organisation and structure and physiology. The many laboratories specialise in most aspects of photosynthesis, from whole plants down to biophysical work on pigments and membrane structure.

The first report of a thermostable hydrogenase (from the red photosynthetic bacterium *Thiocapsa roseopersicina*) emanated from I. N. Gogotov's laboratory at Pushchino. They showed that this hydrogenase had a temperature optimum of 75 °C and was quite stable in air — before this hydrogenases were thought to be very unstable. Now a range of hydrogenases have been reported from various organisms which are reasonably stable and are thus useful in biophotolytic systems which evolve hydrogen gas. This is an active area of research in Gogotov's laboratory as it is part of the Soviet Union's solar energy programme.

Phytotrons, computer facilities, and special equipment services go to make up a very impressive Institute. A detailed report on its activities will soon be available in English. Two other Institutes in Pushchino — those of Biochemistry and Physiology of Microorganisms, and of Protein Research usefully complement the photosynthesis research groups.

In Moscow the Academy's Institute of Biochemistry houses the Laboratory of Photobiochemistry under Academician A. A. Krasnovsky (of Krasnovsky reaction fame — the photochemical reduction of low potential compounds using artificial chlorophyll systems). Krasnovsky's laboratory is studying hydrogen-producing systems using model pigment systems, for example, chlorophylls, TiO_2 particles, viologens, ferredoxins, hydrogenases and platinum. They were the first to show in the 1960s that TiO_2, ZnO and WO_3 could split water with ultraviolet light, evolving oxygen and reducing ferric and quinone compounds. Work continues in placing such systems in micelles and liposomes and on multilayers. At Moscow State University the Laboratory of Chemical Enzymology in Berezin's Chemistry Department is also looking at biological energy converting systems.

Work is progressing on trying to stabilise chloroplast membranes (not yet totally successful, as everyone is finding out) and on growing algae in ponds for subsequent fermentation to methane. They also have an active group on the construction of fuel cells using hydrogenases immobilised on gels and graphite electrodes; an oxidase, for example, laccase, comprises the other half cell. Such fuel cells seem quite stable and operate at high efficiencies.

In Skulachev's Laboratory of Bioenergetics model membranes as photoconvertors are an active area of research. In the Department of Microbiology, Professor E. Kondratieva heads a famous group working on C, H and N metabolism of photosynthetic bacteria and on methane-producing bacteria. The growth of photosynthetic bacteria under dark and light conditions and under various oxygen

Experimental algal pond in Tashkent

tensions has an important bearing on their ability to fix N_2 and evolve H_2 — besides using various carbon compounds as a substrate source. This laboratory has shown that *Thiocapsa* can be grown chemoautotrophically in the dark under oxygen but it needs thiosulphate and CO_2 — it cannot use organic compounds under such conditions. This relates to Pfennig's work in Göttingen on the non-sulphur *Rhodopseudomonas* which can grow in the dark with H_2 and CO_2 when oxygen concentrations are low. These observations seem important since they point to an adaptability of photosynthetic bacteria not hitherto realised. Kondratieva's laboratory is also actively involved in the possible utilisation of photosynthetic microorganisms in solar energy conversion systems.

In the Academy's Institute of Plant Physiology in Moscow, Professor A. A. Nickiporovich heads the Laboratory of Photosynthesis which has a long history of work on factors determining the efficiency of photosynthesis and plant productivity. Nickiporovich heads the group in the USSR Solar Energy Committee looking at biomass as a future source of energy, while, Krasnovsky leads the group investigating the potential of photosynthetic mechanisms as solar energy convectors.

The Republic of Uzbekistan has over 400 algal ponds in operation today. It was an eye-opener to visit the Institute of Microbiology at Tashkent headed by Academician A. M. Muzofarov and run by the Uzbekistan Academy of Sciences in Tashkent. Besides practical research in mycology (the first volume of floral mycology of Uzbekistan having just been published) and fermentative microorganisms, there is a significant effort on algal ecology, physiology and productivity.

Ponds growing green algae under thermophilic and mesophilic conditions apparently operate in many parts of the Republic to provide food supplements for cattle, chickens and silkworms. Yields vary from 30 to 60 tonnes dry weight per hectare per annum, the limiting factor being low winter temperatures of 2 – 5 °C although there is still considerable sunshine. A large system near Samarkand produces a tonne of wet cells per day while much larger ponds are under design. Interesting experiments are also being done with blue-green algae, with water plants like *Lemna* and with fertilisation of cotton with algal suspensions.

At the Ukrainian Academy's Institute of Plant Physiology at Kiev, Professor Grodzinsky heads a team of 400 people who work on various aspects of the agronomy, nutrition, physiology, biochemistry, chemistry and physics of plant growth. Two of the eleven science departments — physiology and ecology, and biochemistry — are directly concerned with photosynthesis. Optimum conditions for productive growth under ideal and stress conditions have been analysed to help in plant selection and agricultural programmes of the Ukraine — which is the largest producer of sugar beet in the world. The chloroplast membranes and their photosystem particles and lipids are being actively studied to try to understand the inherent stability of such membranes in light and also how they might be used in artificial water splitting systems for solar energy conversion.

In Professor Ostrovskaya's laboratory there is an active group studying the localisation in and isolation of photosystems I and II from the chloroplast membranes; it seems that for photosystem II, proteins are more important for stability than the lipid environment. A photosystem II fraction has been isolated which has no contaminating photosystem I particles — this is important for spectroscopic studies.

In Professor Gulaev's laboratory they are looking at the factors limiting photosynthesis in the leaf. Seven factors can be listed and their theoretical and practical interactions are being studied. Such practical work is important in trying to select plants for optimum field growth and also under artificial conditions such as greenhouses where CO_2 fertilisation and waste heat, from power stations for example, can be used to maximum effect.

Many other centres of photosynthesis research exist in this vast country. Three of which I am aware are the Botanical Institutes in Leningrad in Russia, Baku in Azerbaijan, and Minsk in Byelorussia and there must be many more smaller photosynthesis laboratories. My impression is that photosynthesis research has been recognised as being important to the future agricultural, ecological and solar energy prospects of the USSR. ☐

Galactic X-ray sources

from A. N. Parmar and P. A. Lamb

ASTRONOMERS are becoming increasingly aware that to understand X-ray sources better they must observe them over the entire electromagnetic spectrum. Participants at a recent multidisciplinary meeting* presented the results of observational and theoretical studies ranging from the radio to the gamma-ray region of the spectrum.

The evolutionary model for a massive binary X-ray source begins as a 20 $M_\odot$ and a 8 $M_\odot$ star. The more massive star evolves to fill its Roche lobe and transfers its hydrogen atmosphere to the secondary, which becames the more massive component. At this stage the system consists of a massive hydrogen and a helium star, which rapidly collapses and probably explodes as a supernova, leaving behind a neutron star. The hydrogen star becomes a supergiant with a strong stellar wind, providing materal which accretes onto the neutron star: this powers an X-ray source for about 5 million years.

There are many problems with such a simple model. Mass conservation is assumed, although it is known that many such stars are over-luminous for their masses, which implies that they lose mass at a high rate. The effect of mass loss on stellar evolution is not at all clear but some preliminary results were given by E. P. J. van den Heuvel (Amsterdam). The model does not explain the origin of the slow pulsars (with periods of order of a minute) although some mechanisms to slow down newborn, rapidly spinning neutron stars (which have periods of fractions of a second) have been proposed.

Several contributors demonstrated how observations over a particular wavelength range can contribute to our understanding of X-ray sources. The search for radio emission from X-ray sources was covered by B. Burk (Massachusetts Institute of Technogy). In a typical binary system undergoing mass exchange X rays are

---

*An Advanced Study Institute on Galactic X-ray sources, was held at Cape Zunion on 28 May-9 June, and sponsored by NATO, The Greek National Committee for Astronomy and University College London's Department of Physics and Astronomy.

0028-0836/79/390256-03$01.00

often produced in the high density, high temperature, accreting plasma close to a compact star while the radio emission is formed further out by the interaction of the relativistic plasma and the magnetic fields that are generally present. The well known X-ray binaries, Cyg X-1, Cyg X-3, Cir X-1 and Sco X-1 as well as GX17+2, the Galactic Centre and various RSCVn stars have been detected at radio frequencies.

The optical characteristics of high mass binary systems were discussed by J. B. Hutching of the Dominion Astrophysics Observatory (DAO). Detailed spectroscopic studies of eight of the hot supergiant components indicate that although these primary stars are undermassive (compared with normal stars of the same spectral type) their elemental constituents are apparently normal. The transfer of mass is made evident by the emission lines at λ4684 (He II) and the $\lambda\lambda$4640 — 4650 (C III — N III) blend. Both emissions almost certainly occur in the accreting matter.

Analysis of optical light curves for these systems is complicated by the need to correct for non-circular orbits, tidal deformation, X-ray heating, non-synchronous rotation of the primary and the presence of an accretion disk.

A. Cowley (University of Michigan) presented a review of optical investigation of low mass binary X-ray systems. These fall broadly into three groups: first, those in which the optical output from the disk dominates that from the 'normal' star. The optical spectrum then consists of a hot, blue, relatively featureless continum with λ4686 He II emission. An example of such a system is Sco X-1 for which spectroscopic radial velocity measurements imply an orbital period of 0.782 days. However, no eclipse (or pulse) periodicity has been detected in the X-ray data. The second type of system is where the optical emission is dominated by the 'normal' star, for example Her X-1 and Cyg X-2. The latter system contains a low mass population II F star which fills its Roche lobe. A 9.8 day orbital period has been determined for this system by radial velocity measurements. The third type of low mass systems are the cataclysmic variables. These consist of the AM Her types (with strong emission lines and magnetic fields), SS Cyg type systems (common dwarf novae) and some of the X-ray transients (for example AO620-00).

A. K. Dupree of the Smithsonian Astrophysical Observatory (SAO) reviewed recent IUE and Copernicus observations of X-ray binaries. Such observations can lead to a better understanding of many problems such as the interaction between X rays and a radiatively driven stellar wind. High temperature material in an accretion disk or X-ray heated photosphere can also be observed in the ultraviolet. Changes in the ultraviolet spectrum of Vela X-1 may be caused by X-ray photoionisation and heating of the stellar wind. The effect of X rays on the interstellar medium has been detected in observations of both this source and 4U1700-37. Two narrow, highly excited, C IV and Si IV interstellar lines have been detected with absorption features separated by 50 km s^{-1}. These may be produced by the expansion of a 'bubble' of ionisation which expands as the X-ray source photoionises the interstellar medium. Ultraviolet analysis of the chromospheric emission from many of the hot single stars, which are now being found to be X-ray emitters, is an important new means for investigating the intriguing problem of the formation of the coronae.

Observations using the HEAO-1 and Einstein satellites have identified new classes of X-ray emitting objects and made possible a more comprehensive survey of known types of source. The emission of X rays from RSCVn, flare and main sequence stars has now been verified. About 80 discrete sources can be seen in the nearby galaxy M31, whereas the last generation of X-ray instruments are only able to detect the whole galaxy as a single source.

J. Grindlay (SAO) reported recent results on the enigmatic X-ray sources seen in some globular clusters. With the increased positional resolution of the Einstein Observatory it has been possible to measure the offset of the X-ray source from the centre of the optical cluster with precision. From an assumption that the stars in the core have an isothermal velocity dispersion, he has calculated the mean mass of this class of X-ray source. This turns out to be of order 20 $M_\odot$. There is, however, a large error associated with this value (2 $M_\odot$ is allowed for with a confidence of 10%) owing to the uncertainty in position of the optical centre of each cluster.

A hundred years ago

ONE feature of the last eruption of the remarkable volcano of Kilauea, in the Sandwich Islands, is the fact that the great molten lake of lava, occupying a hugh caldron nearly a mile in width, and known as the "South Lake," was drawn off subterraneously, giving no warning of its movements and leaving no visible indication of its pathway or the place of its final deposit. "Other eruptions," writes Dr. Coan to Prof. Dana, in a letter dated June 20, "have blazed their way on the surface to the sea, or while on their subterranean way have rent the superincumbent beds, throwing out jets of steam or of sulphurous gases, with here and there small patches or broad areas of lava. But as yet no surface-marks of this kind reveal the silent, solemn course of this burning river. One theory is that it flowed deep in subterranean fissures, and finally disembogued far out at sea.

From *Nature* **20**, 25 September, 513; 1879.

Previous Copernicus results which have tenatively identified OAO1653-40 with the massive binary V861 Sco were supported by more recent data from the same satellite which was presented by A. Parmar (MSSL). This showed an ultraviolet burst, which in one C III line alone had a luminosity of 2×10^{37} ergs s^{-1}, occurring simultaneously with an X-ray turn on. If it can be shown that V861 Sco is indeed associated with the X-ray source then it becomes a firm candidate for a black hole of mass between 7 and 13 $M_\odot$.

H. Bradt (MIT) described the detection of rapid aperiodic variability in Galactic X-ray sources. This has long been known to characterise Cyg X-1 and Cir X-1 although, with the recent detection of pronounced flaring and millisecond bursts, it also seems that the time variability of these sources is significantly more complicated than was once realised. In the past year, rapid aperiodic variability has been observed from GX301-2 and GX339-4. A 7 to 8 second delay between the arrival times of the optical and X-ray signals from Sco X-1 has been interpreted as the light travel time from the compact body to the primary. Correlated optical and X-ray activity has been found by S. Ilovaisky (Observatoire de Paris, Meudon), when the source flares.

Seven of the 16 known X-ray pulsars have had their orbits accurately measured by Doppler analysis of their varying pulse periods. One source, which may be a system containing a neutron star and a low mass white dwarf is 4U1626-67. S. Rappaport (MIT) reported on the search for orbital motion and the detection of as yet unexplained quasi-periodic bursts with a 1000 s characteristic timescale, which could be caused by material in unstable orbits which decay onto the neutron star.

Rappaport has combined data from the Ariel 5 and SAS-C satellites, and obtained a revised orbit for GX301-2 (4U1223-62) which has been determined with a most probable period of 40.8 days and a non-zero eccentricity. Optical photometry on the other hand suggests a period of about 20 days. Vela X-1 has been shown to have an eccentric orbit. Future observations of the change in the longitude of periastron will enable the amount of central condensation of the primary star to be calculated.

Detailed analysis of the X rays detected during an optical flare from the dwarf nova SS Cyg undertaken by F. Cordova (Caltech) shows the 9 s pulses to have a very sinusoidal shape. However, the pulse phase is unstable which makes a determination of the orbit very difficult. Similar

Problems in hominid taxonomy

We are pleased to have had our recent systematic assessment of hominid evolution recognised in *Nature* (*News & Views*, **278**, 400; 1979). Your Paleoanthropology Correspondent has, however, provided the readers of *Nature* with a misleading analysis of our published work as well as a misunderstanding of systematic procedures followed therein.

Your correspondent was not familiar with the authorship of the formal designation of the new taxon, *Australopithecus afarensis*, Johanson, White and Coppens, 1978 (not Johanson and White as reported). The correspondent also seems unaware of the difference between diagnosis and description in a systematic publication. Features of the dentition (large mandibular canines, three-rooted upper premolars and molar size gradients) and postcranium (lack of third metacarpal styloid process, os *coxaae* anatomy) taken by your correspondent as diagnostic of *A. afarensis* are detailed in the *description* of the species and not the *diagnosis*. Of the suite of characters distinguishing *A. afarensis*, the correspondent mentions only a few dental features and completely neglects diagnostic cranial and mandibular anatomy.

Unfortunately, treatment of our *Science* article (**203**, 321; 1979) fares no better as several errors, in fact, mar the report. For instance, the correspondent reports that the Taung specimen does not have a P$_4$ but that we measured it. In fact, the specimen has two P$_4$s, but we did not measure them because they are unerupted. Similarly, our table of dental metrics (page 322) shows central incisor measurements for five individuals instead of the two reported by your correspondent. The correspondent also states that the *A. afarensis* P$_3$ "has a large outer cusp and a very small inner cusp". The relevant citation from *Science* (page 322) is "A smaller lingual cusp is usually present, but some specimens (A.L. 288-1, 128-23) display only an inflated lingual ridge." The fact that this feature reminds the correspondent of Miocene hominoid P$_3$s emphasises our assertion that the CP$_3$ complex of *A. afarensis* is an important character suite that allies the new taxon with extant and extinct apes and distingushes it from members of other hominid species.

Finally, the correspondent suggests that variation (not variability) in the Hadar sample is excessive and indicative of taxic diversity. We direct the reader to our *Science* paper where all of our metric and morphological comparisons of the Hadar and Laetolil samples with those of extant hominoids support the interpretation that the fossil hominid material is best considered a single, naturally variable, sexually dimorphic taxon.

Nature's policy during the controversy over the status of the Taung skull was "No notice is taken of anonymous communications". (*Nature* **116**, 462; 1925) We favour that forgotten policy.

Donald Johanson

Tim D. White
Department of Anthropology,
University of California,
Berkeley, California.

Our Correspondent replies: While I thank Johanson and White for their response to my recent News and Views comment I must point out that their reply does not effectively refute any of the major points of that comment. One of the major premises of that comment was that the diagnosis of the new species (Johanson, White & Coppens *Kirtlandia*, **28**, 1; 1978) does not adequately differentiate it from *A. africanus*, the closest comparative taxon. If that premise can be substantiated then the validity of *A. afarensis*, as a separate and distinct taxon, can be questioned. The necessity of a clearly stated differential diagnosis was noted by the authors when they quoted Mayr's imperative to "list the most important characters or character combinations that are peculiar to the giver taxon and by which it can be differentiated from other similar or closely related ones" (*op. cit.*, page 8). Diagnoses in the general palaeontological literature show that most workers follow Mayr's dictum. Yet precise differential statements are missing from this diagnosis; those features which qualify *A. afarensis* as a separate species have not been made clear.

Moreover, characters which may have a high degree of taxonomic significance have been described differently in the original diagnosis and in a later publication. The size of the inner cusp of the *A. afarensis* P$_3$ is a case in point. In the diagnosis of the new species it was stated that this feature "is often expressed only as (an) inflated lingual ridge (*op. cit.*, page 6). In a later publication the "often expressed" ridge had become a "usually present" cusp (Johanson & White *Science* **203**, 322; 1979). They cannot have it both ways and the fact that they have described the same important character state differently in two publications does not add strength to their taxonomic claims.

Further confusion in their work is apparent when, in their response, they claim that five individuals were used in obtaining measurements of the upper first incisor. Reference to my comment will show that part of that discussion centred on their claim that *A. afarensis* had broad upper first incisors. The breadth of this tooth is measured in the mesiodistal orientation and reference to their Table 1 (*Science* **203**, 322; 1979) will show that four teeth were measured in this orientation, not five individuals (presumably yielding 10 teeth as they now inexplicably claim.

Moreover, Johanson and White suggest that I have confused, in my comment, the diagnosis of the new species with its description. Again, it is they who are confused. That stated that "certain traits . . .(were) placed in the description due to the lack of comparative anatomical specimens from other species of *Australopithecus*". (*Kirtlandia* **28** 8; 1979). In my comment I pointed out that in characters of the hand, wrist and os coxae not only do comparative specimens exist for *A. africanus* but they are virtually identical in the two species.

The second major point of the News and Views comment did not concern the validity of the new taxon but centred instead on the number of taxa which may be contained in it. The authors acknowledge that the metric and morphological ranges may be broad in *A. afarensis* but they claim in the response that "all" of their comparisons between the ranges in the fossil sample and in living hominoids have supported attribution of the fossil material to a single taxon. They do indeed present (in footnotes) coefficients of variation for three features demonstrating that, in selected features, the range of variation in *A. afarensis* does not exceed that of living hominoids. Figure 6 which purportedly "clearly" (*Science* **203**, 329, footnote 23) compares the range of variation for one *A. afarensis* feature with that of other hominoids is, in fact, an illustration of two distal femora.

In the end, however, the *A. afarensis* sample is an extremely important one and disputes over its taxonomic placement do not minimise that importance. Johanson and White are to be praised for their rapid publication of this material.

---

phenomena, described by T. Chester (Caltech) have been observed from another dwarf nova U Gem. He presented a technique for modelling these variations which preserves the phase of harmonics. Improved upper limits for higher harmonics of the pulses can be extracted.

The gas flow from a primary star to a compact body is complicated and poorly understood, making the interpretation of X-ray spectra very difficult. Spectral features from atomic transitions in iron and other elements have been observed in galactic X-ray sources. With the advent of more sensitive spectrometers, such as on the Einstein satellite, many more spectral features are being discovered. R. McCray (Colorado) showed how the analysis of spectral features will allow a determination of the physical conditions in, for example, the flow of accreting material near a compact object. The 'standard model' (appropriate to the solar corona) of an optically thin plasma, in collisional equilibrium, does not hold near to a compact body or in a supernova remnant. An alternative model, which is similar to that for a planetary nebula, is a central point X-ray source which photoionises its surroundings into highly excited states, even at low temperatures. Here, the Auger effect and fluorescence will be very important and radiative recombination lines may dominate the spectrum.

N. Shakura (Sternberg Astronomical Institute) has calculated the characteristic scale of turbulence in a disk which leads to an estimate of α (the ratio of the stress to the pressure in the outer part of a disk). His result, $\alpha \sim 10^{-3}$, differs significantly from previous estimates. Simulations using the precessing, twisted accretion disk model proposed to explain the 35 day cycle of Her X-1 which were presented by J. Petterson (University of Illinois) require α to be of order unity. This is not necessarily inconsistent with Shakura's work as α may vary throughout the disk. □

review article

Contact inhibition and malignancy

M. Abercrombie*

Strangeways Research Laboratory, Worts' Causeway, Cambridge, UK

The role of contact inhibition in influencing the behaviour of malignant cells is discussed in a review. Although tissue culture cannot simulate the immense complexity of the conditions in vivo, *some of the distinctive features of malignant invasion can be conveniently observed with this technique. The evidence derived from this technique indicates that defective contact inhibition of movement of malignant cells does contribute to their invasiveness.*

COMPONENTS of the locomotor machinery of cells have been intensively studied, and a coherent hypothesis about how cells move is being developed. In contrast, little work has been done to characterise the locomotor behaviour of cells, principally the conditions that determine their direction of movement. This is in part because direct observation of the cells is only possible in the artificial conditions of cell culture. In particular, little attention has been paid to the aberrations of behaviour of malignant cells which can be observed in culture in terms of invasion, and which can be confidently predicted. In the context of the incoherent picture that unanalysed cell movement presents at first glance, the movement of malignant cells may not seem in any way distinctive. It may also be that the interpretation I have given to the invasive aspects of malignant behaviour *in vitro*, in terms of defective (not necessarily absent) contact inhibition, has given rise to doubts because it has seemed over-simplified. Nevertheless in my opinion the cardinal points remain, that invasion—the distinctive feature of malignant behaviour—can be observed in cell culture where normal cells do not invade and that a contribution to malignant invasion seems to be made by a defect in normal contact inhibition. These are the points I wish to discuss: first, how the extent of invasion may be assessed with various tumour types in culture and second, how their invasiveness compares with defects in the contact inhibition reactions of the various tumour cells.

Patterns of invasion in culture

The method we have used for assessing invasion involves confronted cultures[1] consisting of two foci of cells (explants) placed about 1 mm apart. Various measurements and observations can be made after the outgrowths have met. In our technique explants of normal and malignant sarcoma fibroblasts have been confronted with a standardised chick heart fibroblast explant, which has proved best for several reasons[2]; the choice in any case must be arbitrary. Six tumours have been studied in detail—mouse sarcomas 311, BAS56, S180, FS9, MClM and a mouse melanoma. The following observations have been made on cultures fixed 24 h after fusion.

Normal mouse muscle fibroblasts confronted with the standard chick heart fibroblasts show a very high degree of obstruction, the invasion zone (the strip occupied by cells from both explants) having a mean width of only 20 μm as shown in Fig. 1*a*. By contrast, confronting each of the six tumours with the standard chick fibroblasts resulted in invasion zones between 130 and 290 μm wide, as is illustrated for BAS56 and MClM in Fig. 1*b*, *c*. Nevertheless, there was still some obstruction of invasion in three of these tumours (311, BAS56 and mouse melanoma), as indicated by consideration of the between-to-side ratios (the ratio, for each explant, between the distance migrated towards the other explant and the mean distance migrated from its free sides). In these three cases, the ratios were less than unity for both the fibroblasts and tumour cells. The cells of S180, the tumour on which our original measurements were made[3] (but which in our experience is indistinguishable from S37 and has perhaps become confused with it) were peculiar in this respect. The between-to-side ratio was unity for both fibroblasts and S180 sarcoma cells, indicating that invasion was completely unobstructed. Nevertheless, film analysis reveals some slight obstruction of S180 cells at the fibroblast front[4] as will be described later.

The assessment of obstruction in the remaining two tumours, FS9 and MClM, is complicated by their non-reciprocal behaviour when confronted with the standard chick fibroblasts. This is best illustrated using the invasion index[2], a measure of the distance of infiltration standardised for the outward velocity from the explant which can, of course, be used separately for both cell types and which takes a value of zero when a cell type is totally stopped by the other and 1.0 when it is totally unimpeded by the other. For 311, BAS56, mouse melanoma and S180 the invasion index was approximately the same for the tumour cells and fibroblasts in each experiment (reciprocal invasiveness) but varied from 0.2 to 1.0 according to the tumour. For FS9 and MClM, however, the extent of invasion of the fibroblasts was markedly less than that of the sarcoma cells (non-reciprocal

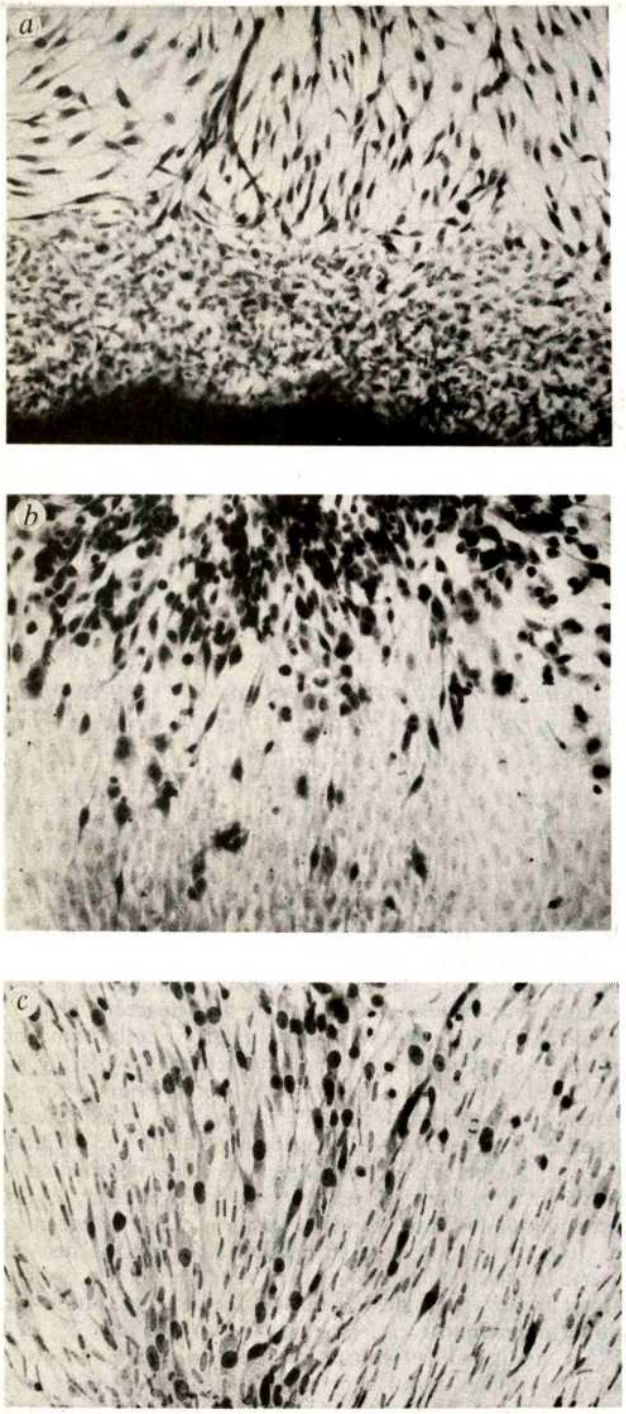

Fig. 1 Confronted explants fixed 24 h after fusion showing the invasion zone. In each case chick heart fibroblasts have migrated from below towards: *a*, Mouse muscle fibroblasts (darker nuclei)—an example of very low invasiveness, ×80. *b*, Mouse BAS56 sarcoma cells (large dark nuclei)—an example of reciprocal invasiveness, ×80. *c*, Mouse MClM sarcoma cells (large dark nuclei)—an example of non-reciprocal invasiveness which also shows the effect of contact guidance (see text), ×122.

invasiveness). The fibroblasts either get out of the way or are overrun. In FS9 the sarcoma invasion index was 0.6 and the fibroblast 0.1, and in MClM the sarcoma index was 1.5 (the sarcoma cell velocity actually increased after contact with the fibroblasts because of contact guidance) and the fibroblast index was 0.2. In these two cases, the actual distance invaded by the fibroblasts was one-third to one-quarter of that of the sarcoma cells, in spite of the fact that the outward velocities of the fibroblasts exceeded those of the sarcoma cells.

Contact inhibition

The term contact inhibition refers to the phenomenon of a cell ceasing to continue moving in the same direction after contact with another cell. It is not always operataive. To assess the part played by contact inhibition in invasion in culture we have to determine the obstruction to movement of the invading cells produced by contact with the normal fibroblasts. A useful 'static' measure of contact inhibition is the overlap index, which expresses the observed number of overlaps of cell nuclei as a proportion of the number to be expected if the nuclei were distributed at random. A homotypic overlap index is concerned with one kind of cell only, but of more immediate interest is the heterotypic overlap index, which is provided by the invasion zone of confronted populations. In this case obstruction is indicated when the number of nuclear overlaps of cells of the two different types is diminished compared with the random expectation of these overlaps[3,5]. It is necessary to score nuclear rather than cytoplasmic overlaps because of the faintness and irregular outline of the cytoplasm. Since it is a requirement that the overlaps result from cell locomotion, inaccuracies in quantification can arise from the clumping of cells due to the drawing together of contractile processes (to be distinguished from the cyclic phenomenon of true locomotion) or from the occurrence of mitosis in dense cultures where the cells cannot move away. Furthermore, the presence of even small amounts of collagen between cells can reduce the effectiveness of their mutual contact and give rise to anomalous results.

Any deviation from a random distribution of freely moving cells towards a more evenly spaced distribution (that is, any overlap index of less than 100%) means that obstruction has occurred. But a single heterotypic overlap index is obtained from the number of overlaps between two cell types and, since non-reciprocal contact inhibition has been recognised, it has become clear that one of the two cell types may be obstructed much more than the other. Thus the index of overlapping may provide a distorted picture of the behaviour of the mixed culture.

A method of obtaining a 'dynamic' index from observations of living cells has been developed for detailed analysis. It necessitates classifying the results of collisions between the two types of cell as observed in timelapse filming. Although this overcomes the limitations of the heterotypic overlap index, only a limited sample of collisions can be observed in reasonable time, particularly since clearcut collisions have to be selected. Contact inhibition is observed as one or both colliding cells stopping and perhaps immediately turning aside. Stopping will also occur at random, without collision, and therefore the excess has to be estimated. At what point does the stopping occur after contact? As seen in plan view it does not usually occur immediately after cytoplasmic contact has been made. Indeed, homotypic encounters in fibroblasts commonly show a considerable degree of cytoplasmic overlap and there may even on occasion be nuclear overlapping before contact inhibition[6,7].

It is useful at this stage to mention a confusion that has arisen over the terms overlapping and underlapping. The overlapping so far referred to consists simply of the state of superimposition of one nucleus on another, regardless of whether the upper or lower cell, by its movement, produced the superimposition (upper and lower are themselves ambiguous terms with reference to gravity) and also regardless of which type of cell is above or below when two cell types are involved. Unfortunately the state of overlapping has been confused with the acts of overlapping and underlapping. It is perhaps best to refer to one cell as either moving outside another cell, meaning on the side exposed to the medium, or moving between another cell and the substratum. From the point of view of contact inhibition all that matters is that the cells should make contact—the form of contact is irrelevant. Bell[8] has made a careful analysis of the origin of homotypic overlapping (crisscrossing) of Py 3T3 cells and found that the overlapping results from the movement of one cell between another cell and the substratum. Since no estimate of contact was made, however, it is not clear how this observation leads him to call into serious question the hypothesis that tumour cells are invasive by virtue of having lost the capacity to undergo contact inhibition.

Contact inhibition in non-malignant fibroblasts

I now consider the normal background of contact inhibition amongst non-malignant fibroblasts in culture. Abercrombie and Heaysman[1] first examined the question by measuring the homotypic overlap index in cultures of two explants of chick heart fibroblasts fixed after they had reached confluence. Several other investigations using this static method were subsequently reported (see, for example, refs 9, 10). The dynamic method of time-lapse filming for examining homotypic contact inhibition was used non-quantitatively by Abercrombie and Ambrose[11] and then quantitatively by Veseley and Weiss[12] and by Guelstein *et al.*[13]. Heterotypic estimations with mouse muscle fibroblasts confronted with chick heart fibroblasts formed the controls for the similar work on sarcoma cell invasion already referred to[2]. Whenever the static method has been applied to fibroblasts in a population that was not too dense, the number of overlaps observed has been very significantly lower than the statistical random expectation. This lack of overlapping is often referred to as monolayering.

It is evident, therefore, that contact inhibition is a general feature of fibroblast collision. But can it totally obstruct cell movement? Steinberg and his colleagues (see for example, ref. 14) have investigated this question in dense cultures of chick embryo fibroblasts, partly because of my own somewhat exaggerated claims which assumed that the displacements observed were largely in the form of oscillations. (There is in fact more mobility than that, many fibroblasts interchanging their positions at a speed of several micrometres per hour.) Steinberg's purpose has been, however, to establish the existence of motility in confluent monolayers—from which he concludes that obstruction is not total—rather than to make comparisons with motility in sparse populations or with migration from explants into cell-free space. Measurements by Abercrombie and Heaysman[15], Gail and Boone[16] and others show that when such comparisons are made, obstruction is clearly apparent.

The differential adhesion hypothesis of Steinberg and colleagues on contact inhibition amongst fibroblasts is, in my opinion, untenable as it stands. They suppose that what is inhibited is the act of passing outside and that this inhibition is due to a failure of the cell migrating outside to make effective adhesion to the dorsal surface of the cell it contacts. Typically, however, contact inhibition in fibroblasts seems to occur to a cell after it begins to pass between another cell and the substratum. Such a cell therefore undergoes contact inhibition without ever leaving its normal substratum and therefore without changing its adhesion[16,17]. Furthermore, one of the most conspicuous features of contact inhibition in fibroblasts is the contraction undergone by the cell's front end, an event which is not accounted for by the adhesion hypothesis. A notable instance of such contraction occurs in non-reciprocal contact inhibition, where the cell that is not inhibited proceeds on its way while the cell that is inhibited (if contact is made by its leading edge) retracts, leaving the way clear in front of the first cell.

The hypothesis of differential adhesion as an explanation of contact inhibition should not, however, be discarded. It may well be important in cells other than fibroblasts[4,12]. Even for fibroblasts, there might be an effect of a lack of adhesiveness of the dorsal surface which is masked by the contractile reaction. There are difficulties in testing whether the dorsal surfaces of fibroblasts are defective in adhesion independently of the contractile reaction. The scattering of a population of dissociated fibroblasts onto the surface of fibroblasts already adherent to the substratum fails to differentiate between the two hypotheses since the contractile reaction may prevent the dissociated cells from spreading as they settle.

Contact inhibition in malignant fibroblasts

I now turn to consider the relation of contact inhibition to the behaviour of malignant fibroblasts.

In the experiments we have made with explants in confronted cultures, the contact inhibition between homotypic cells within any one population has an important role. The tendency of contact-inhibited cells to move towards cell-free space produced outward radial migration from an explant; non-malignant cells with high contact inhibition migrate radially with a high velocity. Most malignant cells studied also show the effect, although since their contact inhibition is commonly lower than that of non-malignant cells they do not usually show the outward drive so powerfully. Indeed, with S180 cells we have found the outward drive to be negligible. For example, a sample of cells in an S180 outgrowth showed no significant preponderance of movements away from the explant over movements towards the explant[4]. Their motility is therefore almost entirely diffusion-like in spite of their high contact inhibition, at least at relatively low density. The explanation is probably that in contrast to the other tumours investigated the majority of changes in direction of S180 cells are spontaneous rather than the result of collision between cells. This is to be expected since S180 cells are more often out of contact with each other than the other tumour cells at the same density and they show a comparatively low persistence in direction when moving freely. E. M. Stephenson (personal communication) has recently found that the outward drive is also ineffective in mouse melanoma cultures. Although homotypic contact inhibition of the melanoma cells, judging by nuclear overlaps, is also high there is only a small but statistically significant excess of movements away from rather than towards the focus.

Although much has been made of homotypic overlapping amongst transformed cells as an index of their malignancy, the correlation, if any, is by no means clear. Most observations have been qualitative. Projan and Tanneberger[10] however, made an extensive quantitative study of tumours by means of the overlap index and found a broad range of indices from well within the normal range, to an extremely high level (2%–91%). This was in contrast to the indices of non-malignant cells which they found were concentrated within the range 3%–19%. It seems evident, therefore, that malignant cells are characterised by their broad variability as compared with normal cells, although their median level is no doubt distinctly higher. It should be added that it is not clear how a lowered homotypic contact inhibition of malignant cells could contribute to their invasiveness.

The high degree of obstruction between two confronted normal fibroblast explants, such as between chick and mouse fibroblasts, apparently results from their high heterotypic contact inhibition[2]. In a free outwandering the fibroblasts move at approximately 300 μm per day, while in confronted culture they are brought almost to a standstill. How far then, can the invasion of sarcoma cells in confronted culture be accounted for by defects in their heterotypic contact inhibition?

In sarcomas 311 and BAS56 and the melanoma, the between-to-side ratios indicate some obstruction of invasion and there is a relatively low heterotypic overlap index indicating the presence of contact inhibition[2] (melanoma data from E. M. Stephenson, personal communication), although both the extents of invasion, and the overlap indices, are higher than with two confronted normal fibroblast explants. There is no indication of any non-reciprocal inhibition, and the invasion is approximately mutual. Furthermore there is a characteristic diversion of cells at the junction of the two populations, both cell types turning in an orthogonal direction, which is probably a manifestation of their tendency to move towards cell-free space. It seems likely that because of the incidence of heterotypic contact inhibition, the outward drive from the sarcoma explant is largely arrested by the fibroblast obstruction, invasion being by a diffusion-like movement.

In S180 the between-to-side ratios gave no indication whatever of obstruction and, correspondingly, there was no deviation in heterotypic overlap from random expectation[3]. Later studies by film[4,11] showed a complete absence of contraction and paralysis of the ruffled membrane on contact on the part of either sarcoma cell or fibroblast. The films showed, however, a slight slowing down of the sarcoma cells while they were amongst the fibroblasts and a slight obstruction where they met the free edge of the fibroblast population. An unusual aspect of the invasion of S180 is that the sarcoma cells are almost invariably outside (on the dorsal surface of) the fibroblasts, which may well be a consequence of the fact that the sarcoma cells are rounded and project very much further above the substratum than do the flattened fibroblasts. There is no mutual diversion of the two populations.

In contrast to the three tumours (311, BAS56 and the mouse melanoma) which showed reciprocal invasion, two others, FS9 and MClM, showed non-reciprocal invasion. Significantly, these two tumours showed non-reciprocal contact inhibition. In FS9, the invasion indices revealed that the fibroblasts were almost totally obstructed whereas the tumour cells were only partially obstructed and, when similar cultures were studied by direct filming (Abercrombie and Turner, unpublished), the fibroblasts seemed totally inhibited on contact with the sarcoma cells though the sarcoma cells were not completely inhibited by the fibroblasts. The fibroblasts show immediate retraction on contact with the sarcoma cells when in head-on collision, while the sarcoma cells continue their locomotion. When a sarcoma cell collides with the side of a fibroblast, the fibroblast generally shows a high degree of contact inhibition; consequently, almost all the invaders are sarcoma cells. For MClM, the other example of non-reciprocity, the invasion indices show that the sarcoma cells are probably not obstructed at all. In direct filming[18] non-reciprocity is clearly seen; the fibroblasts to some extent move out of the way of the sarcoma cells after retraction, and to some extent are overlapped by them. Hence the heterotypic overlap index is relatively low even though heterotypic contact inhibition is absent or greatly reduced in the sarcoma cells. (The static measurements of overlapping can thus fail to detect some instances of failure of contact inhibition.) For this tumour the mutual diversion of cells observed with the cells of other tumours is not detectable. For both FS9 and MClM the outward drive from the sarcoma explant clearly persists into the fibroblast explant's zone (Fig. 1*c*).

Increased heterotypic overlapping in other tumours has been demonstrated in a mouse ascites carcinoma and in a mouse melanoma (by overlap index[9]) and a rat sarcoma (by filming[12]). Guelstein *et al.*[13], however, found no increased heterotypic overlapping by filming in a mouse transformed cell line.

Conclusions

It is easy to describe invasion in culture but less easy to be certain of its relevance to invasion *in vivo*. This is all the more so because there is no quantative measure of invasion *in vivo*; one has to depend on histological descriptions. Furthermore it could be that a number of transformed cells are erroneously assumed to be malignant, thus obscuring a possibly strong correlation between *in vitro* and *in vivo* invasive behaviour. It seems more probable however that 'begign' and 'malignant' are relative terms, spanning a continuous gradation of invasiveness.

Neither is it easy to account for the behaviour responsible for invasion in culture. I have concentrated on some of the complexities of contact inhibition of movement and their correlation with the overall pattern of invasion. An important outcome is the concept of non-reciprocity, formulated originally by Heaysman[18]. Its simplest interpretation requires the presence of separate emitters and receptors. Where there is no contact inhibition in either of the contacting cells, neither would have emitters or receptors for each other; where there is reciprocal inhibition, both cells would have both. The emitters and receptors must be assumed to be constant in a standard fibroblast but would differ independently as between the various cells. A tumour like MClM, which is able to induce contraction of a fibroblast—a sign of contact inhibition—would be regarded as a strong emitter, and a weak receptor, because it is not itself inhibited by the fibroblast. A tumour like S180, producing no contraction of contracted fibroblasts, would be a weak emitter and weak receptor, and one like FS9 a strong emitter but intermediate receptor. It would be instructive to test different kinds of tumour against each other, since different kinds of fibroblasts seem to vary very little in their emitters and receptors.

In addition to contact inhibition, variable adhesiveness might play a part in determining invasiveness. There may be two effects here, a homotypic effect in which cells of the same type adhere closely to each other and so prevent penetration, and a heterotypic effect in which the invaders experience obstruction because of their strong adhesion to the invaded cells. In both cases these effects are to be distinguished from the relatively low adhesiveness which is the basis of Steinberg's hypothesis of contact inhibition. The contribution to obstruction of these two possible effects of high adhesiveness cannot be accurately determined. The hypothesis that tumour cells have a low adhesiveness has been current since the time of Coman[19]. It may be said, however, that since adhesion is by definition reciprocal, the non-reciprocity found in some tumour invasions is not accounted for.

Other factors probably play a minor part in invasiveness. For instance, contact guidance by cells is incompatible with contact inhibition, but when contact inhibition is low, it is possible that the tumour cells may be guided by the underlying normal cells. Indications that this may be happening have been found in filmed S180 invasions[4]. With tumours (311 and MClM) the possible effect of some diffusable agent has been detected, there being a slight inhibition of the outgrowth of the fibroblasts before junction with the tumour cells.

The study of invasion in culture provides an opportunity for investigating the many facets of invasiveness but many important gaps remain. There has been comparatively little work on the behaviour of normal cells, and the invasion of carcinomas has not been studied at all. It should be possible to approach the *in vivo* environment of cells by using three-dimensional hydrated collagen gels as substrates. The question of the role of mitotic pressure in invasion is not suited to investigations by tissue culture. In spite of the fact that so much work was devoted in the 1920s and 1930s to the supposed growth of cultures there was never any evidence that growth as opposed to migration played any part whatever. Cells cannot be pushed along a solid substratum to which they are adhering.

Molecular abundances in IRC+10216

The observed molecular column-densities in IRC + 10216 can be matched by chemical equilibrium calculations for $T \sim 1{,}250$ K, $P \sim 100$ dyn cm^{-2}, and no graphite grain formation. Condensation of silicon carbide into grains may explain the low observed abundances of SiO and SiS. A compressed gaseous shell may be formed between successive dust shells lost by the central variable carbon star during each of its cycles.

THE IR object IRC+10216 is a barely visible, cool carbon star surrounded by an expanding, dusty molecular envelope[1-3]. Parameters for carbon stars are poorly known but[4] $R_* \simeq 1{,}000\,R_\odot$, $T_* \simeq 2{,}200$ K, $L \simeq 10^4 L_\odot$. There are grains close to the surface of the star at around 1.5 R_* from the photosphere[5]. The inner optically thick IR component[6] has a radius of $10R_*$ at $T \simeq 600$ K, whereas the outer optically thin component has a radius of 60 R_* at $T \simeq 375$ K. Recent work[7] replaces this two-component model by a continuous temperature distribution, but the temperatures at the corresponding radii are about the same. Much further out, the upper limit on the HCN molecular envelope[8] is 1,200 R_* and the extended CO envelope[9,10] is seen out to at least 3,800 R_*. Since Solomon *et al.*[11] observed microwave CO emission, 15 further molecules have been identified in its extended envelope, and abundance estimates are available for 14 of these (Table 1). We have performed molecular equilibrium calculations in an attempt to match the observations. We wish to determine if the relative abundances can be explained by a 'freeze-out' model: this supposes that chemical equilibrium holds close to the central star's photosphere, but that as the temperature and density fall in the circumstellar wind, molecular reaction rates drop rapidly enough for molecular abundances to be 'frozen' near their equilibrium values at some point near the star.

A suitable criterion for 'freeze-out' to apply is $\tau_{\mathrm{chem}} \gg \tau_{\mathrm{exp}}$ where τ_{chem} is the time scale for an e-fold change in the abundance of some molecule and τ_{exp} is an expansion time scale given by the time to cross a density scale-height in the shell. For IRC+10216, $v \approx$ constant[1] and we assume $\rho \propto (r/r_{\mathrm{inner}})^{-2}$, that is, steady flow. Then $\tau_{\mathrm{exp}} \approx r_{\mathrm{inner}}/v_{\mathrm{exp}} \approx 10^8$ s if we assume[12] that $r \approx r_{\mathrm{inner}} \approx r_{\mathrm{star}} \approx 10^{14}$ cm. In the outer shell $\tau_{\mathrm{exp}} \propto r$ and so the expansion time scale is longer. Calculation of τ_{chem} requires knowledge of the key reactions producing and destroying the molecules of interest and is beyond the scope of this article. However, we note that: (1) photochemical and ion-molecule reactions are probably unimportant in this neutral dusty shell (Wannier and Linke[13] report severe upper limits on molecular ion abundances); (2) if all neutral bimolecular reactions of type $A + BC \rightarrow AB + C$ had the typical rate constant $K = 10^{-11}$ cm^3 s^{-1}, then $\tau_{\mathrm{chem}}(A) = (Kn(BC))^{-1} \approx 10^4$ s to 10^8 s for $n_{\mathrm{total}} = 10^{10}$ cm^{-3} and depending on whether the reactant BC had the abundance of CO or of a less abundant species such as CH respectively. This suggests that there will be equilibrium near the photosphere ($n_{\mathrm{total}} \approx 10^{15}$ cm^{-3}; see ref. 14) and that freezing-out will start to occur for $n_{\mathrm{total}} \lesssim 10^{10}$ cm^{-3}, which is about the density at grain formation in the models of Lucy[12]. In the outer shell $\tau_{\mathrm{chem}}/\tau_{\mathrm{exp}} \propto r$ and so chemical reactions will become progressively less important. Since τ_{exp} is quite short compared with the time scales for chemical reactions in interstellar clouds[15], no chemistry at all may be going on in the outer shell, and so a freeze-out model seems appropriate.

The abundances in Table 1 have been derived both from IR absorption and microwave emission lines. Because of the radio telescope beam widths involved (about 60″), we must justify the merging of these two abundance sets. For HCN and CO, Hall and Ridgway[16] derive column densities N(HCN) > 1.5×10^{18} cm^{-2}, N(CO) = 10^{20} cm^{-2} from IR absorption lines and so N(HCN)/N(CO) > 1/67; this agrees satisfactorily with the ratio N(HCN)/N(CO) = 1/60 derived by Kwan and Hill[17] from their model and microwave observations, and is not very different from the ratio 1/150 found by Morris *et al.*[18]. However, Allen and Knapp[19] have recently derived N(CO) = 4×10^{17} cm^{-2} from the $J = 2 \rightarrow 1$ ^{13}CO line, in substantial agreement with the earlier figure of 2×10^{17} cm^{-2} found by Wilson *et al.*[8]. These emission measurements are averages over a beam of diameter about 1′. Wannier *et al.*[20] report a strong radial abundance gradient for CO in IRC+10216. If the gradient is steep enough, then a large beam will effectively dilute the observed line strengths roughly in proportion to the area of the beam. The absorption measures are with a beam whose area is about 400 times smaller and so we might expect them to lead to a column density about 400 times larger, or about 10^{20} cm^{-2}, as found by Hall and Ridgway[16]. Thus the absorption and emission measurements for CO seem to be roughly consistent. There may be difficulties if the density gradient is less steep than about $1/r^3$. We have adopted the absorption measurements in Table 1. The beam dilution effect has been allowed for by Morris[1], who used a $1/r^2$ density model in deriving column densities for SiS, SiO, CS and HC_3N, and so his emission measurements are on essentially the same scale as the absorption measurements. The value adopted for CN comes directly from the emission measurement[19] of the ratio to CO; for C_2H we derived a column density from the data in ref. 21. For C_4H and C_3N we do not know in detail how the column densities were

The column densities have been measured at millimetre wavelengths in emission (radio beamwidth typically 1′) and at micrometre wavelengths in absorption (IR beamwidth typically 3″). The figure for NH_3 is from Betz (personal communication and ref. 46). The adopted relative abundances are with respect to $CO = 10^{20}\ cm^{-2}$ and are taken from the entries marked with an asterisk—see text. The presence of SiC in the form of grains has been inferred from an 11 μm emission feature[27]. The equilibrium abundances correspond to $\log P = 2$, $\log T = 3.1$.

derived; the source is described as point-like[22] and so the large-beam column densities give lower limits to the true values. For comparison with our calculations we have adopted the set of relative abundances in Table 1; we assume that they form a consistent set to within one order of magnitude.

Calculations

Chemical equilibrium calculations have been carried out for 126 molecules containing 25 elements using a program written by Clegg (described in ref. 23). The calculations cover a range of temperatures and pressures expected to occur in carbon star atmospheres, namely

$$-5 \leq \log P \leq +3, \quad 3.10 \leq \log T \leq 3.45$$

with grid spacings of 1 in $\log P$ and 0.05 in $\log T$. Two C/O ratios were used: (1) 1.76, the averaged carbon star value used by Lucy[12] and (2) 5, the value used in calculations by Tsuji[14]. The O/H ratio was chosen to agree with the CO/H_2 ratio found by Kwan and Hill[17] (assuming essentially all the oxygen is locked up in CO). All other elements were given solar abundances. Many of the molecules considered have dissociation energies uncertain by 0.3 eV, and so our calculations are only accurate to one order of magnitude. Molecular data were taken from Tsuji[14,24], updated from the JANAF tables[25]. Two situations were considered: First with no grains present, and second with graphite grains present wherever the partial pressure P_C of monatomic carbon exceeds the vapour pressure P_{V_1} of monatomic carbon over graphite; the constraint $P_C = P_{V_1}$ was imposed in those regions of the pressure–temperature plane where the supersaturation ratio $S(C) \equiv P_C/P_{V_1} > 1$ in the no-grain calculations. The results are shown in Fig. 1, in which agreement with observation is best where the density of dots is highest, in Table 1 and in Fig. 2.

Discussion

The best agreement within the range of temperature and pressure considered clearly occurs for $\log T = 3.1$, $\log P = 2$, with $C/O = 1.76$ and no grains present; Table 1 shows that the agreement in that case is remarkably good, considering the coarseness of the (P, T, C/O) grid. This suggests that most molecules are formed in equilibrium, and that the anomalies are due to special circumstances. This result is similar to that found by Hall and Ridgway[16]; however, they considered only three molecules relative to CO and compared them with Tsuji's calculations[14] with $C/O = 5$, a value for which we found much less satisfactory agreement between our calculations and observations. We confirm their conclusion that the agreement is poor if we allow graphite grains to form.

The inclusion of graphite grains by using the constraint $P_C = P_{V_1}$ gives much poorer agreement with observation. This is particularly striking for HCN and C_2H_2; in the absence of grains, reasonable agreement with observation is obtained over a wide range of P, T; when grains are added the region of agreement shrinks drastically—for C_2H_2, no P, T combination gives agreement even within an order of magnitude. This is true for $C/O = 1.76$ or 5.

This result is curious, since the supersaturation ratio is so large ($S = 32$ at $\log P = 2$, $\log T = 3.1$) that it would be very surprising if graphite grains did not form—the critical value of the ratio is usually considered to be between 2(ionic nucleation) and 10 (heterogeneous nucleation). Also the visual extinction and IR emission clearly imply the presence of grains. A clue is afforded by the two molecules, SiS and SiO, that stand out in our equilibrium calculations as underabundant: the observed abundances are down by factors of 10^3–10^4 on the equilibrium abundances. This strongly suggests that silicon is mainly locked up in SiC (or silicate) grains in IRC + 10216, as in other carbon stars[26]. An 11 μm feature is attributed[27] to SiC particles, though the absence of a 10-μm emission feature seems to rule out a significant amount of silicate grains. Morris *et al.*[28] discuss the low abundance of SiO in IRC + 10216 in similar terms. This suggests that, contrary to the traditional view[29], SiC grains form before graphite grains. There is some evidence from recent observations[26] that graphite forms further out than expected. Our calculations show that, for $\log P \approx 2$, SiC condenses out before C if $C/O \lesssim 1.1$, but we were not able to obtain good agreement with observed abundances with this low C/O ratio: species containing two or more carbon atoms are much too low in abundance. At higher C/O ratios, the condensation temperatures of C and SiC are sensitive to the pressure but never differ by more than about 200 K. Although $S(C) = 1$ at higher temperatures than $S(SiC) = 1$, we find that $S(SiC)$ rises much more sharply than $S(C)$ as the temperature is lowered. Given that grain formation is a highly non-equilibrium process it is quite possible that SiC grains deplete Si, and that freeze-out occurs, before carbon grains form. This conclusion seems to be strengthened when account is taken of the temperature differences between the grains and the radiation[30] and further work is in progress at Sussex on this aspect.

Two other molecules, NH_3 and CN, stand out as overabundant compared with equilibrium calculations, which may suggest that the freeze-out assumption is not a good one. To obtain agreement for NH_3 we would need a lower temperature and/or higher pressure while for CN we would need a higher temperature and/or lower pressure; CN is very sensitive to temperature. It is possible that both are formed on grain surfaces[31]; estimates by Turner and Gammon[32] for interstellar CN give CN/CO ratios in the right range for agreement with the observed value in IRC + 10216.

We did not include HC_5N and HC_7N in our calculations as no thermochemical data are available. However, Clegg (unpublished) found their abundances consistent with equilibrium predictions (within rather large errors) using estimated bond energies for these molecules. The abundances of some other large molecules including C_2H_4, C_2H_6, and C_6H_6 were estimated from the atomic number densities. We found that their abundances were not great enough to affect the overall calculations.

At the values of pressure and temperature that give good agreement with observation, the gas pressure is considerably higher than found in time-independent models of expanding atmospheres of cool stars. We have obtained a copy of the program used by Lucy[12] for carbon stars and computed a wide variety of models using different values of T_* (photospheric temperature), L (luminosity), M_* (mass), S_c (critical supersaturation ratio) and C/O. In all cases, the general structure of the model is similar. Grain formation always occurs at around $\log T = 3.25$, $\log P = -3$. No point in the atmosphere is anywhere near the conditions $\log T = 3.1$, $\log P = +2$, as can be seen from Fig. 1. The same applies for the model of Menietti and Fix[33] for cool stars of more normal carbon abundance, so this result is probably generally true for cool expanding atmospheres.

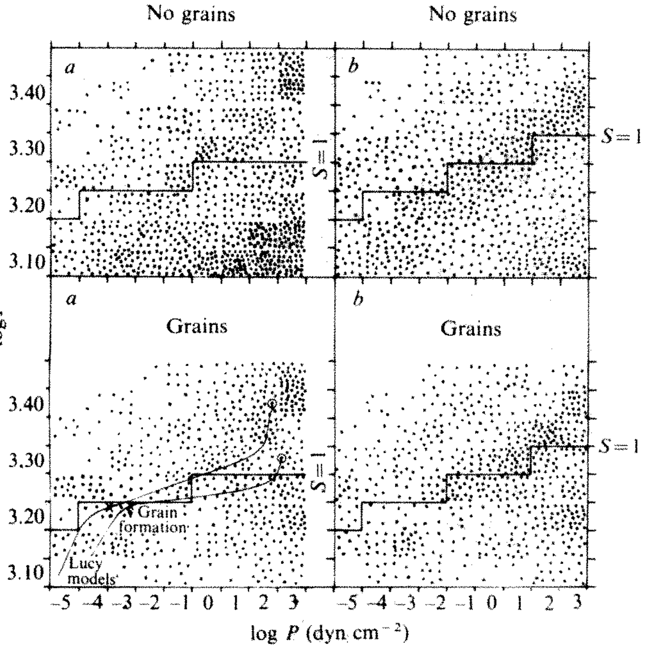

Fig. 1 A comparison of equilibrium abundances at different pressures, temperatures and C/O ratios with abundances observed in IRC + 10216. *a*, C/O = 1.76; *b*, C/O = 5. The calculations were done with grid spacings of 1 in log *P* and 0.05 in log *T*. Each grid point is represented on the diagram by a box and the results of the calculations are represented by dots within the box. Two dots indicate agreement for one molecule to within a factor of 10; six dots indicate agreement for one molecule to within a factor of 3. Lucy models for two different photospheric temperatures ($\log T_* = 3.40$ and 3.30) are shown. The grains and no-grains cases are identical for temperatures above $S = 1$ (S is the supersaturation ratio).

However, our study of the Lucy model does show (Fig. 1) that at points before grain formation we can still obtain moderate agreement with observation for some molecules, notably HCN, HC_3N, C_2H_2, CN, SiS and SiO, although for the first three this is mainly because of the wide range of P and T for which agreement is possible. Other molecules, CH_4, CS, C_4H and C_3N, disagree by several orders of magnitude. In particular, the observed abundances of CH_4 and NH_3 are factors of 10^5 and 10^7 respectively higher than they would be in equilibrium in the Lucy model before grain formation; agreement with observation can only be obtained at lower temperatures. Formation of CH_4 is known to occur catalytically on grain surfaces at low temperatures[34] and it is therefore possible that most molecules are formed in equilibrium before grain formation and then have their abundances 'frozen-in' as the reaction rates drop with density but that CH_4 and the other saturated-bond molecule NH_3 are formed far out on grains and so do not have their equilibrium abundances. However, that would not explain the other discrepant molecules.

Furthermore, there does not seem to be a unique freeze-out point in the Lucy models—there is no single P, T point giving a best agreement with observation. Radial abundance curves were plotted for all the molecules, using the Lucy model, and it was found that some molecules agree with observation before grain formation, some after and some not at all. To explain this, it is necessary to modify the 'freeze-out' picture. Equilibrium will be a good approximation only if the reaction rates are fast enough to keep up with the changes in P, T as the atmosphere moves out. Since reaction rates are proportional to number density, we expect equilibrium to fail first for the least abundant molecules. We have made rough estimates that suggest that for at least some molecules equilibrium fails before grain formation. Ion–molecule reactions could maintain equilibrium further out, but seem unlikely to be occurring in IRC + 10216, as mentioned earlier[13]. Once one molecule is out of equilibrium, all the other abundances will change and we should really do the equilibrium calculations holding fixed the abundances of those molecules that have already 'frozen out'. It would be desirable to perform a full kinetic calculation to study this problem further.

Another difficulty with the Lucy model is that the terminal velocity of the wind is considerably higher (typically 40 km s^{-1}) than observed in IRC + 10216 (see Table 1). The terminal velocity v_∞ is insensitive to most parameters of the model. But a reduction in C/O to ~1 would reduce v_∞ sufficiently and would cut down the grain density—this could explain why we find better agreement in the absence of grains, though, as mentioned earlier, preliminary calculations seem to exclude C/O $\lesssim$ 1.1. Alternatively, as suggested by Lucy[12] on other grounds, the grains in IRC + 10216 may be larger than he assumed. The reduced grain opacity could then account for a lower v_∞. SiC grains would also have a lower opacity in this temperature range[35].

An interesting test of the freeze-out model is provided by the ratio HCN/HNC. In chemical equilibrium this ratio is independent of gas pressure and abundances and only depends on the relative binding energies and the temperature (the partition functions are almost identical). The binding energy of HNC is lower than that of HCN by[36] 0.63 eV, from which we predict HCN/HNC $\approx$ 300 at $\log T \approx 3.1$. The observed ratio of antenna temperatures is 10 (Zuckerman, personal communication) but the HCN line is optically thick. The correct ratio can be obtained from $T_A(H^{13}CN)/T_A(HN^{12}C)$ and scaling up by $^{12}C/^{13}C \approx 40$ (ref. 13). Since $T_A(H^{13}CN) \approx 1.3$ K (ref. 37) and $T_A(HN^{12}C) \approx 0.4$ K (Zuckerman, personal communication) we find HCN/HNC $\approx$ 130, in fair agreement with our prediction.

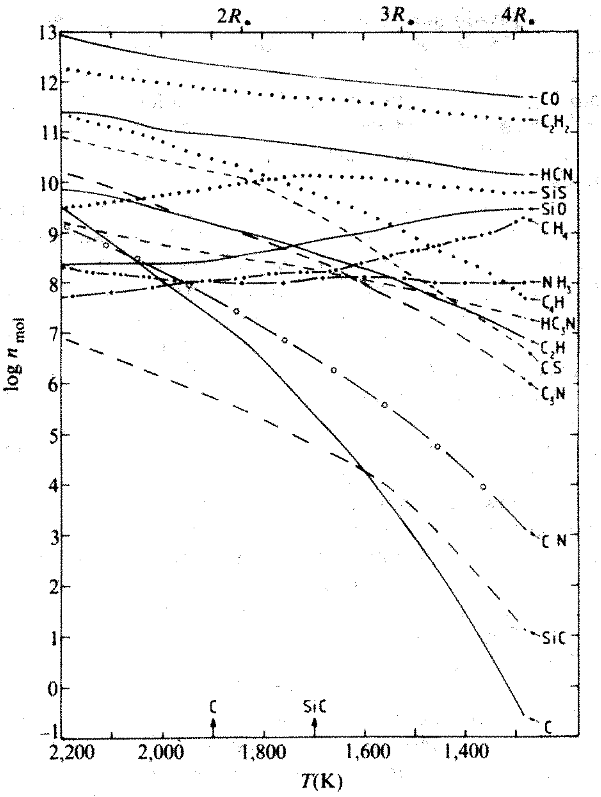

Fig. 2 Radial molecular abundance curves for chemical equilibrium based on the temperature distribution of Crabtree and Martin[7]. C/O = 1.76 and $T_* = 2{,}200$ K are specified and a $1/r^2$ density distribution is assumed. The temperatures at which S(C) = 1 and S(SiC) = 1 are indicated. No grain formation is allowed for.

Certainly the observed ratio is quite different from those found in many interstellar clouds[38], where HCN ≈ HNC.

We have found that agreement of equilibrium calculations with observation seems to be possible only in conditions of slightly lower temperature and much higher pressure than are together consistent with conventional models of steady outflow. We have therefore sought a model in which cool compressed regions arise naturally. IRC + 10216 is known to be variable on a time scale of about 600 days[39] and grains and gas may well be ejected only at one phase in the cycle and so be lost in shells or 'puffs'. We speculate that this can be invoked to form the compressed regions suggested by the high pressure found for the best fit. If an inner shell absorbs radiation from the star, it shields any outer shell. The inner shell could therefore overtake the outer shell and so perhaps compress the gas between them. This gas would also be shielded from the stellar radiation and so could cool, perhaps reaching the cool, high pressure conditions suggested by the observed molecular abundances. Close to the star there may well be a hot region, either a chromosphere or a heated shock region[40], and the dust shells would act to block UV radiation arising there. Dusty regions near such a UV source could be both a site for CN and NH_3 formation on grains[31,32] and a sink for SiS, SiO molecules onto grains. This model predicts that molecular lines found close to the stellar surface (for example, NH_3; Betz, personal communication) may be variable with time.

Whether or not this model is correct, there is no doubt that the observed abundances cannot be explained in terms of freeze-out in a conventional model of the expanding atmosphere of a carbon star. The fact that we have found a good fit for two-thirds of the molecules and can suggest why the other four molecules do not fit may mean that freeze-out does occur but that actual expanding atmospheres have much higher pressures for a given temperature than does the Lucy model. That would be the case if a $1/r^2$ density dependence were valid even close to the stellar photosphere.

Future work

Our attempt to see if the 'freeze-out' model can explain the IRC + 10216 abundances has suggested some useful future lines of investigation. First, a chemical kinetics calculation for these species in a neutral, adiabatic gas flow is desirable and is underway at Texas. Even using approximate rate constants may help to identify key reactions for the destruction and formation of the observed molecules and to evaluate the accuracy of the assumption of a unique freeze-out point for all species. Second it would be useful to construct Lucy-type models of expanding atmospheres with SiC grains rather than C grains; it is hoped to do this at Sussex in the near future. On the observational side, it is important to know the radial abundance gradients of the molecules so that we can accurately match the observations[20]. It would also be useful to have consistent measurements for all molecules, using as far as possible the same techniques and methods of reduction. Discovery of more molecules may help elucidate the chemistry in the inner shell close to the star. Finally, it would be valuable to obtain more measurements in other similar objects, such as CIT 6[19,41], to see whether the abundance pattern is repeated.

We thank Leon Lucy, Harry Kroto and David Slavsky for helpful discussions, A. Betz for communicating his results for ammonia before publication, and B. Zuckerman for comments. R.E.S.C. acknowledges support from the Robert Welch Foundation of Texas and E.M.M. acknowledges an SRC studentship.

Mélange in the Trondheim Nappe suggests a new tectonic model for central Norwegian Caledonides

Gregory S. Horne

Wesleyan University, Middletown, Connecticut 06457

Extensive mélange exists near the base of the Trondheim Nappe, indicating tectonisation of syndepositionally deformed chaotic deposits. The mélange is associated with other features that are characteristic of forearc accretionary prisms. Such a tectonic setting for the Trondheim Nappe has profound implications for the evolution of the Scandinavian Caledonides.

THE Trondheim Nappe underlies a physiographic basin south of Trondheimsfjord in the central Norwegian Caledonides[1]. It is the crestal plate of a pile of generally west-dipping nappes that crop out consecutively eastwards across Scandinavia[2]. These nappes wedge out and converge to the west and seem to represent a telescoping of Lower Palaeozoic facies from eugeoclinal rocks at the top of the pile in the west to miogeoclinal-paralic strata in lower sheets to the east[3]. Thin slices of Precambrian basement are incorporated within and between the various allochthons.

Tectono-stratigraphic setting

The Trondheim Nappe contains a complex internal stratigraphy that has experienced several phases of penetrative deformation, at least one phase of regional metamorphism, and a complex history of thrusting. Scarcity of fossils within these strata makes correlations among the various units tenuous and speculative. This has caused confusion and controversy over stratigraphic nomenclature and structural interpretation.

The succession along the eastern margin of the Trondheim region is generally of upper greenschist–lower amphibolite facies[4–6]. Lithic similarity and stratal continuity among eastern areas indicate correlation with Wolff's[4] key sequence (Table 1). Fossils are known only from an early Silurian graptolite locality in the Kjølhaug Group[4], and a Dictyonema locality in uncertain relations with correlatives of the Fundsjø Group[5]. Elsewhere, strata presumed correlative with the middle of the sequence include a significant serpentinite-pebble conglomerate with early–middle Ordovician gastropods that indicate both American and European affinities[5].

The western succession of low greenschist facies rocks in the Trondheim region reveals extreme complexity among various sedimentary and volcanic facies (P. Ryan and D. Skevington, personal communications). The nomenclature of Vogt[7] persists for major units (Table 1), but stratigraphic details are subject to progressive revision with the discovery of new faunas. Most graptolite and shelly faunas indicate Ordovician provincialism with strong North American identity[8,9]. The most significant aspect of the western sequence is the several kilometres-thick accumulation of spillitic basalts and pyroclastic strata that constitute the Støren Group[10].

The western succession is separated everywhere from the eastern succession by a belt of unfossiliferous, higher metamorphic grade schists and gneisses assigned to the Gula Group[4]. Correlations between eastern and western successions are not only governed by the stratigraphic significance of the Gula but also depend on regional structural interpretations as well as the particular tectonic model that is favoured. For example: (1) Roberts *et al.*[11] have interpreted the Gula as the older core of a mushroom-shaped antiform, correlating the eastern and western sequences as outward younging inverted limbs of that antiform. (2) Gale and Roberts[10] modified the mushroom model by lumping all the groups within the Trondheim Supergroup, conjectured to include various continental-margin and oceanic facies foreshortened by obduction before antiformal folding. Thus, the Gula was called the miogeoclinal equivalent of the eugeoclinal–backarc assemblage of the Hovin–Horg and Sulåmo–Slågån groups, also equivalent with the sea floor volcanics in the Støren and Fundsjø groups (assumed to be the same). (3) In contrast, Gee and Zachrisson[12] contended that the superficially similar eastern and western successions are quite distinct and within separate nappes. The western sequence was presumed to have been deposited on the Gula, and then both thrust over the eastern sequence, which was later thrust eastwards as the Köli Nappe.

More recent interpretations are variations of the double nappe hypothesis described above[1,2,13], but also include extensive later translation of the Trondheim sequences/nappes farther eastward across the Baltoscandic Shield.

Table 1 Major Stratigraphic units of the Trondheim Supergroup

Area	Group	Lithology	Age
Western[7]	Horg	Calcareous sandstone, shale, quartzite conglomerate	
	U. Hovin	Tuffaceous sandstone, slate, polymict conglomerate, limestone	Caradoc–Ashgill
	L. Hovin	Graywacke, slate, felsic extrusives, andesite porphyry	Arenig–Llanvirn
	Støren	Greenstone, pillow basalt, metatuff, pyroclastic deposits	
Central	Gula	Phyllite, metagraywacke, amphibolite, biotite–sillimanite schist	?
Eastern[4]	Slågån	Phyllite, slate, metasiltstone	
	Kjølhaug	Phyllite, metagraywacke, slate	Llandovery
	Sulåmo	Metagraywacke, phyllite, slivers of greenstone	? Mid-Ordovician
	Fundsjø	Greenstone, amphibolite, quartz keratophyre	? Tremadoc

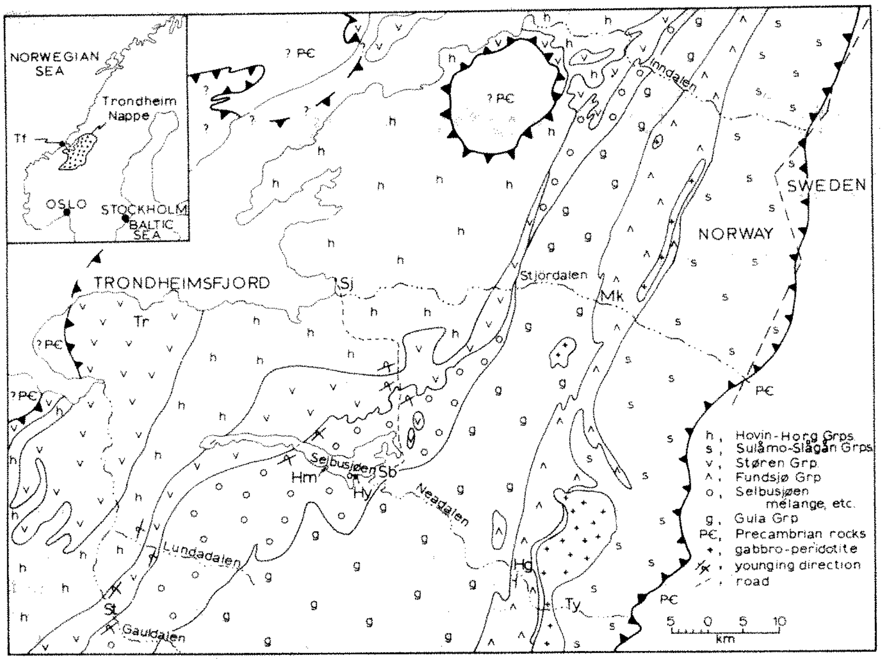

Fig. 1 Generalised geologic map of the Trondheim region, Norway (modified after Wolff[15] and Gee[2]); Hg, Hegset; Hm, Hammar; Hy, Hoöya; Mk, Meråker; Sb, Selbu; Sj, Stjördal; St, Støren; Tf, Trondheimsfjord; Tr, Trondheim; Ty, Tydal.

The resolution of these conflicting interpretations involves understanding the nature of the relationship between the Gula and adjacent volcanic groups, Støren to the west and Fundsjø to the east. The contacts have been variously described as normal sedimentary, conjunctive–tectonic, disjunctive–tectonic, and highly tectonised with thick phyllonites and mylonites. The best exposures that reveal the Støren–Gula relationship are along the shores of Selbusjøen (Fig. 1).

The Selbusjøen mélange

The succession north of Selbusjøen was divided into upper sedimentary (Hovin), middle volcanic (Støren), and lower sedimentary units[14]. The lower sedimentary unit is upper greenschist facies and is best exposed along the lake's north shore; it comprises phyllite, metagraywacke, and quartz schist. The same units extends east of Selbusjøen[6] grading progressively into coarser and higher grade metamorphic facies typical of the Gula Group. Mélange fabric was first recognised along the south shore of Selbusjøen and subsequently found on the north shore and in other areas.

Mélange fabric

The most evident aspect of mélange fabric is phyllite with fragmental debris principally of metagraywacke. Large blocks range from rounded boulders (Fig. 2) to angular phacoids; none reveal definitive evidence on origin of fragmentation. Phacoids may be boudins or pulled-apart interbeds, and boulders may have been rounded by tectonic rotation within the pervasively sheared phyllite matrix; some or all fragments also may be clasts of sedimentary origin. Less coarse debris grades through cobbles to pebbles and granules, but without apparent sorting of fragments. Some units are rich with graywacke debris, similar to pebbly mudstone (Figs 3 and 4), but even within small outcrops clast fabric ranges widely in size and angularity. In spite of deformational overprints on fragmental fabric, fragmentation seems to have been brittle in some zones (Fig. 3) and ductile in others (Fig. 4).

Volcanic material exists as lentils within the highly sheared phyllite around Selbusjøen. Discrete packets of greenstone up to several metres in length commonly lie encased within metasedimentary strata. Along the north shore of the lake apparent layers or large lentils of greenstone occur for several kilometres east of the Støren contact. The Hammar *presqu'ile* and Hoöya island (Fig. 1) consist mostly of volcanic and associated sedimentary rocks, and they may be knockers or olistoliths within the mélange. Relationships surrounding the large volcanic masses north-east of Selbu (Fig. 1) are not clear, but an olistostrome is suggested.

Associated rocks

Associated with the mélange of bouldery–pebbly phyllite are extensive zones of very highly sheared and crenulated phyllite with thin interbeds of metagraywacke–siltstone which have been mullioned into rods plunging easterly coincident with most other linear structures. Fragmentation in these zones certainly was tectonic, but could have occurred while the strata were relatively unlithified. Other thin zones between major lithic units are intensely tectonised into phyllonites and mylonites secondarily mineralised with quartz and sulphides. These latter zones were obviously deformed well after metamorphism.

In contrast to the penetratively deformed zones described above, other zones of weakly deformed and metamorphosed sediments also are found spatially associated with mélange. The physical and geometric relationships of these sediments with either the mélange or the highly sheared and mullioned zones is not clear, but contrasts in degrees of deformation and metamorphism indicate that the sediments are younger and

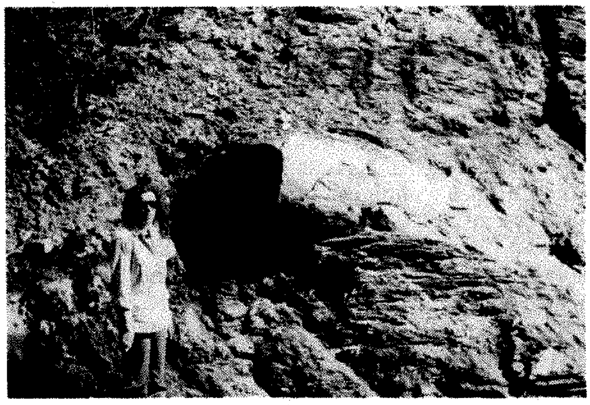

Fig. 2 Rounded metagraywacke boulder within pervasively sheared phyllite mélange, roadcut along the south shore of Selbusjøen.

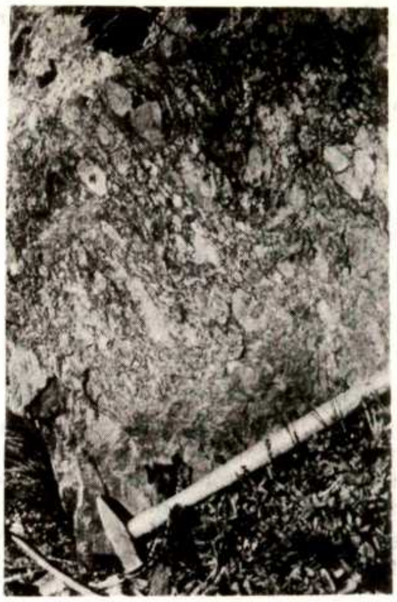

Fig. 3 Dense clast fabric of metagraywacke and volcanic debris in phyllite; note the preferred orientation of clasts, but lack of apparent flattening or stretching.

probably discordant on the more highly deformed rocks. The sedimentary strata consist of turbiditic graywacke and syndepositionally disturbed mudstone–phyllite; evidence of downslope slumping and distortion is abundant. Near the Selbu–Stjördal road weakly deformed phyllite unconformably overlies more highly deformed quartzite–phyllite–schist retrograded from almandine grade; the unconformity cross-cuts layering in the latter rocks with minor erosional relief.

Oleson and others[6] included all the rocks that crop out around the eastern part of Selbusjøen in the Gula Group. However, it is not known how these rocks relate to other parts of the Gula, or even if they should be included in that Group as it is used by others[4,5]. For instance, Wolff[15] implied that they were part of the Hovin Group. On the basis of graded bedding, truncated strata, and pillow lavas it is evident on both shores of Selbusjøen and along the Selbu–Stjördal road that the Selbusjøen rocks are overturned and lie stratigraphically beneath Støren volcanics. The contact at the base of the Støren is sharp wherever exposed and seems to be primary, but it could be tectonic. The south-eastern extent of the Selbusjøen sequence is obscured by easterly gradational and continual increase in metamorphic grade up to staurolite–kyanite schists and gneiss. The latter rocks are obviously part of the Gula Group as it is used by all workers in the region.

Regional relationship

Several major valleys (-dalen) cut through the central Gula belt and provide sections across the critical contacts with adjacent units. Gauldalen cuts through the Gula Group south-east of Støren (Fig. 1), where pillow lavas indicate that the Støren Group is overturned and youngs to the north-west. The Støren–Gula contact is clearly exposed at the south-west edge of town, and seems primary with low grade metasedimentary rocks in direct contact with greenstone; graded bedding corroborates evidence from pillows indicating the metasediments underlie the volcanics. The 'upper' (north-west) part of the Gula is similar to the rocks exposed around Selbusjøen: sheared and crenulated phyllite, graphite schist, banded metachert, weakly metamorphosed slate–graywacke, and pervasively sheared mélange with metagraywacke debris, all infested with hypadyssal sheets of trondhjemite. Geochemical studies of larger plutons of trondhjemite in the Støren area indicate derivation from low-K tholeiitic basalt by partial fusion[16]. Five kilometres south-east of Støren, rocks of higher metamorphic grade and more typical of the Gula Group are in tectonic contact with the rocks described above; cataclasites and submylonites are present within the abrupt and narrow contact zone.

The Lundadalen section lies midway between Støren and Selbusjøen (Fig. 1) and also shows Støren Group pillow basalts to be overturned and to young westward into the exposed inverted contact with the Hovin Group of sedimentary strata replete with younging criteria. The Støren–Gula contact is not exposed, but the two groups are pervaded, respectively, with quartz keratophyre and trondhjemite sheets near the contact. A narrow zone at the western side of the Gula belt adjacent to the Støren Group consists of sheared phyllite containing both volcanic and metasedimentary debris; this zone is followed eastward by alternating belts of metagraywacke, greenschist, phyllite, metachert, amphibolite, and biotite gneiss, with numerous highly tectonised shear zones.

Neadalen extends south-east of Selbusjøen to Tydal (Fig. 1) and clearly shows the gradational increase of metamorphic grade easterly through the Gula Group. Excellent exposures in the ravine at the Hegset Dam show west-dipping pillow lavas of the Fundsjø Group to young into a sharp and steeply west-dipping fault contact with the Gula Group to the west. This is one of the few exposures of the Fundsjø Group that contains unequivocal younging direction, a point of regional controversy and tectonic significance[3,4]. Of comparable significance is the presence of the 5 km-thick mafic layered igneous complex just east of the Fundsjø outcrop belt; the bowl-shaped body lies encased within an envelope of sheared pelitic rocks and it contains cumulate structures indicating that it is not inverted[6].

Stjördalen extends from Trondheimsfjord towards the Swedish border (Fig. 1); it contains the controversial section that bears on the various structural interpretations of the Trondheim region[2,4,11,12]. This section shows a fanning of structural surfaces from east-dip at the west through vertical in the centre to gentle west-dip at the east; major tectonic wedging[3] must be implicit in any model that explains the fan structure. None of the critical contacts is exposed in the Stjördalen section. The Støren–Gula contact is a 1-km-wide tectonised zone of sheared alternating slices of metavolcanic and metasedimentary rocks of various textures and metamorphic grades. The Gula–Fundsjø contact

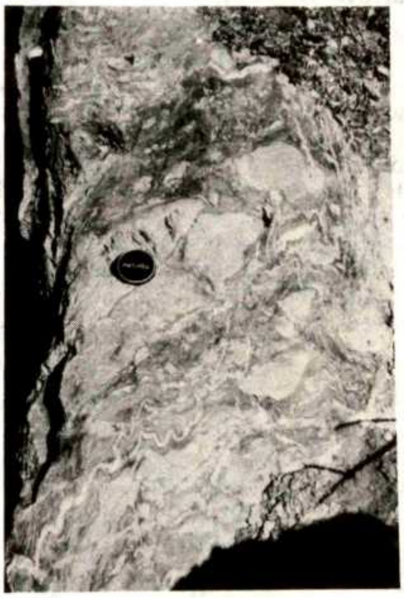

Fig. 4 Phyllitic pebbly mudstone with unsorted and unoriented fragmental debris of graywacke; note apparent disaggregation of block edges.

has been pervasively infested by massive sills of diorite and concordant sheets of trondhjemite.

The Inndalen section (Fig. 1) is similar to the Stjördalen section with its fanning structure. The contacts of the Gula Group with adjacent volcanic groups are not well exposed, but are highly sheared zones pervaded with layers of diorite, trondhjemite, and quartz keratophyre. The eastern contact of the Fundsjø Group is also tectonised and followed eastward by various metasedimentary strata and zones of phyllite mélange, which are separated by a major strike fault from another slice of metavolcanics and the succeeding Sulåmo–Slågån Groups farther to the east.

Summarising the critical relationships among the major rock units from west to east: (1) the contact between the Støren Group and the Selbusjøen mélange (and associated rocks) appears to be primary; (2) the contact between the Selbusjøen rocks and rocks more typical of the Gula Group is usually tectonic, but south-east of Selbu it seems to be gradational; (3) sheets and larger bodies of trondhjemite are commonly associated with both the Selbusjøen rocks and the Gula Group; (4) at least at one locality the Fundsjø Group demonstrably youngs to the west into a fault contact with the Gula Group; (5) mélange is also present east of the Gula Group associated with the Fundsjø–Sulåmo contact; (6) a regional fanning of structural surfaces exists from the Hovin Group in the west to the Sulåmo Group in the east.

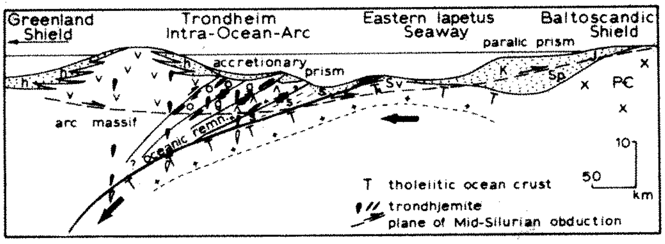

Fig. 5 Hypothetical schematic section through Early Silurian intra-ocean-arc complex within contracting Iapetus Ocean, showing relationship of various Trondheim Supergroup units to accretionary prism; J, Jämtland Supergroup; K, Köli Supergroup; Sp, Eocambrian Sparagmite; Sv, Seve Supergroup; other symbols as on Fig. 1.

The accretion model

No single criterion is exclusively indicative of any unique environment, but associations of many features are usually the best indicators of most tectono-sedimentary settings. Although mélange genesis is not restricted to forearc environs, mélanges are commmonly characteristic of that tectonic setting[17-19]. Moreover, mélanges are often associated with other features which together indicate subduction zones and the resulting accretionary prisms[19-23], such as: packets of slumped upper-slope apron deposits (as seen overlying the Selbusjøen mélange); localised internal unconformities within accretionary basins (as near the Selbu–Stördal road); localised conglemorates internally derived from submarine ridges of accreted slices (as in the Sulåmo–Slågån Groups); slices of oceanic volcanics included among the slices of accreted sediments (as within the Selbusjøen mélange and in the Stjördalen section); tectonised contacts between the various accreted slices, with development of shear zones, phyllonites and mylonites (as seen in each of the sections described here); inclusion of pods and sheets of basal ophiolite sequences or layered mafic complexes and ultramafics (as near Tydal); gross fanning structure across the accretionary prism of imbricate thrusts, from low-lying slices in the front to steep wedges at the rear (as the fan structures in the Stjördalen and Inndalen sections); anatexsis of oceanic crust leading to infusion of the accretionary prisms by swarms of hypabyssal derivatives of partial fusion of tholeiitic basalt (as in the Gula Group and Selbusjøen rocks).

Figure 5 shows how a model of a forearc accretionary prism applied to the Trondheim Nappe may explain much of the structural-stratigraphic complexity in the region. The model suggests that oceanic lithosphere from an eastern Iapetus seaway was subducted westward beneath an intra-ocean-arc system consisting of low-K tholeiites and associated sublittoral deposits, which are now represented by the western succession of the Trondheim Nappe. As the eastern seaway closed through the Ordovician, slices of outer slope and abyssal sea floor deposits, and remnant slivers truncated from culminations on oceanic crusts, were accreted into and to shallow depths beneath the leading edge of the arc system; these slices are now represented by the eastern succession of the Trondheim Nappe. The central succession of the Gula Group and Selbusjøen mélange probably represent foreshortened inner slope and trench deposits squeezed between the arc front and accreting sea floor slices, resulting in initial penetrative deformation and metamorphism. Later evolution into the Silurian merely involves the obduction of the Ordovician intra-ocean-arc complex on to the converging Baltoscandic continent with additional deformation and regional metamorphism, and attendant thrusting of continental margin and basement slices both beneath and in advance of the obducted plate. Although the eastern Scandinavian nappes are not directly the topic of this article, the continued eastward translation of this obducted pile across Scandinavia could easily result in further imbrication and subdivision of its leading edge into the Jämtland, Köli, and Seve Nappes, with or without basal Sparagmites.

This model is admittedly speculative and at variance with all previous models. For example, the polarity of subduction advocated here is opposite to that proposed in most other models[3,10]. Yet, I think that this new hypothesis greatly simplifies interpretations of the regional tectonic history, and that it may help solve many of the fundamental problems in the Trondheim region. It also may apply to other comparable parts of the Appalachian–Caledonian orogen, as in central Newfoundland[24,25].

This research was conducted while I was a Senior Fulbright-Hays Research Scholar at Norges Tekniske Høgskole. I thank the staffs of the US Educational Foundation in Norway and the Geologiske Institutt in Trondheim for support, particularly Professor Christoffer Oftedahl. John Dewey, Daniel Karig, Richard Nickelsen, David Roberts, John Rodgers and Frederik Wolff provided advice and comments.

Experimental determination of interacting sequences in ribosomal RNA

Alex Ross* & Richard Brimacombe†
Max-Planck-Institut für Molekulare Genetik, Abteilung Wittmann, Berlin-Dahlem, FRG

An approach is described for determining secondary structure in large RNA molecules, in which families of short interacting RNA fragments are isolated and identified as such by two-dimensional gel electrophoresis. Data covering over half of the 16S ribosomal RNA from Escherichia coli *are presented, including two long-range interactions.*

ELUCIDATION of the three-dimensional organisation of ribosomal RNA is essential to an understanding of ribosome structure and function. Unfortunately, progress in this direction has been hampered by the lack of suitably direct experimental methodology for the determination of secondary and tertiary structure in large RNA molecules. The techniques which have so far been applied to the problem include modification with single-strand-specific reagents such as kethoxal[1-3], binding of oligonucleotides[4,5], and analysis of the cutting points of ribonucleases[6-8]. All these methods, although they have yielded valuable information on the location of single-stranded regions, leave the central question essentially unanswered, namely, how are the double-stranded regions of the sequence base-paired with one another? For this it has been necessary to resort to predictions (either manual or computer-aided (for example, ref. 9)) of the sequences most likely to interact, an exercise which may well lead to totally erroneous conclusions, particularly in the case of the complex ribosomal RNA molecules, where evidence is accumulating that widely separated regions of the primary sequence are involved in mutual interactions[10-13]. A secondary structure prediction of the type just mentioned was made for the 16S ribosomal RNA from *Escherichia coli*[6], but in this case the situation was even more unsatisfactory, as the model not only disagreed with much of the corresponding kethoxal data[1-3], but also was derived from a primary sequence which contained a large number of errors.

In this article, we present a direct experimental approach to the determination of interacting sequences in RNA, and describe its application to the 16S RNA from *E. coli*, taking advantage of the fact that the complete nucleotide sequence of this molecule has now been established[14,15]. The method is in principle very simple. The RNA is digested with the single-strand-specific S_1 nuclease[16], and the products are separated on a two-dimensional gel electrophoresis system similar to that used by Vigne *et al.* to identify two interacting fragments of 5S RNA[17]. The first gel dimension is run in non-denaturing conditions and the second in denaturing conditions, with the result that RNA sequences which were involved in interactions in the first dimension become dissociated and appear as pairs or families of fragments in the second dimension. The nucleotide sequences of these fragment families are then determined. The results so far have yielded information on over half of the 16S RNA molecule, and are presented in the form of a working model for the secondary structure of the regions concerned, including two long-range interactions.

Isolation and controlled digestion of the 16S RNA

In this type of experiment, it is important to minimise perturbations of the secondary structure during isolation and digestion of the RNA. For this reason we have used a particularly mild isolation procedure in which the RNA is separated from protein on a sucrose gradient containing dodecyl sulphate, sodium chloride and magnesium acetate. Figure 1 shows, using ^{3}H- and ^{14}C-labelled 30S subunits, that this procedure leads to total deproteinisation of the 16S RNA, and that the RNA sediments significantly faster than a parallel sample run on our more usual gradient system containing EDTA in place of magnesium[18], indicating a rather more compact conformation. For the digestion experiments, 16S RNA was prepared in the same way from ^{32}P-labelled 30S subunits, and was treated with S_1 nuclease at *p*H 5.5 in a buffer containing the same concentrations of sodium

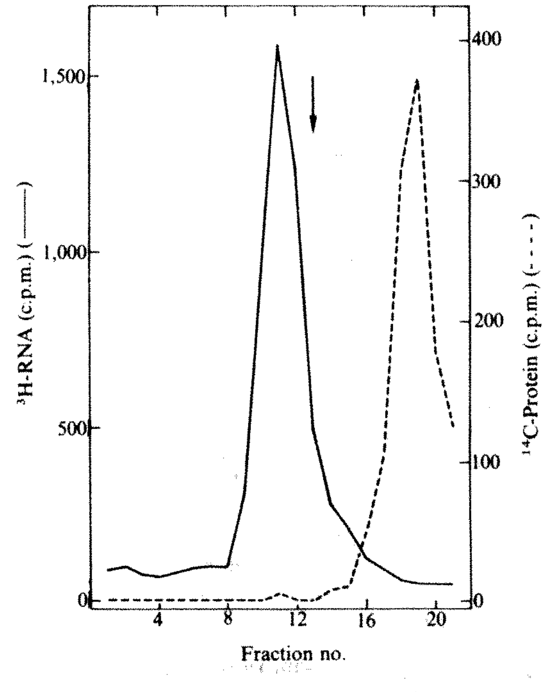

Fig. 1 Isolation of RNA. 30S subunits from *E. coli* MRE 600 were isolated as described elsewhere[25,27], and were applied to 7.5–30% sucrose gradients containing 0.1% SDS, 0.3 mM magnesium acetate, 10 mM sodium chloride and 10 mM Tris-HCl, *p*H 7.8. The gradients were run at 8 °C for 20 h at 25,000 r.p.m. The sample in this case was of 30S subunits (25 A_{260} units) labelled with ^{3}H in the RNA moiety and ^{14}C in the proteins. Direction of sedimentation is from right to left, and the arrow denotes the position of the 16S RNA peak on a parallel gradient containing 2 mM EDTA in place of NaCl and magnesium acetate. For S_1 nuclease digestion experiments, ^{32}P-labelled 30S subunits (~6 A_{260} units, 10^9 c.p.m.) were applied to the gradient, and the fractions containing ^{32}P-RNA were pooled, precipitated with ethanol and taken up in 0.1 ml of 0.3 mM magnesium acetate, 10 mM NaCl and 2 mM Tris-HCl, *p*H 7.8. The solution was brought to *p*H 5.5 by addition of 20 mM triethanolamine acetate, *p*H 5.5, and was incubated for 1 h at 20 °C with S_1 nuclease (100 units per A_{260} unit RNA), followed by a further hour with proteinase K (60 μg).

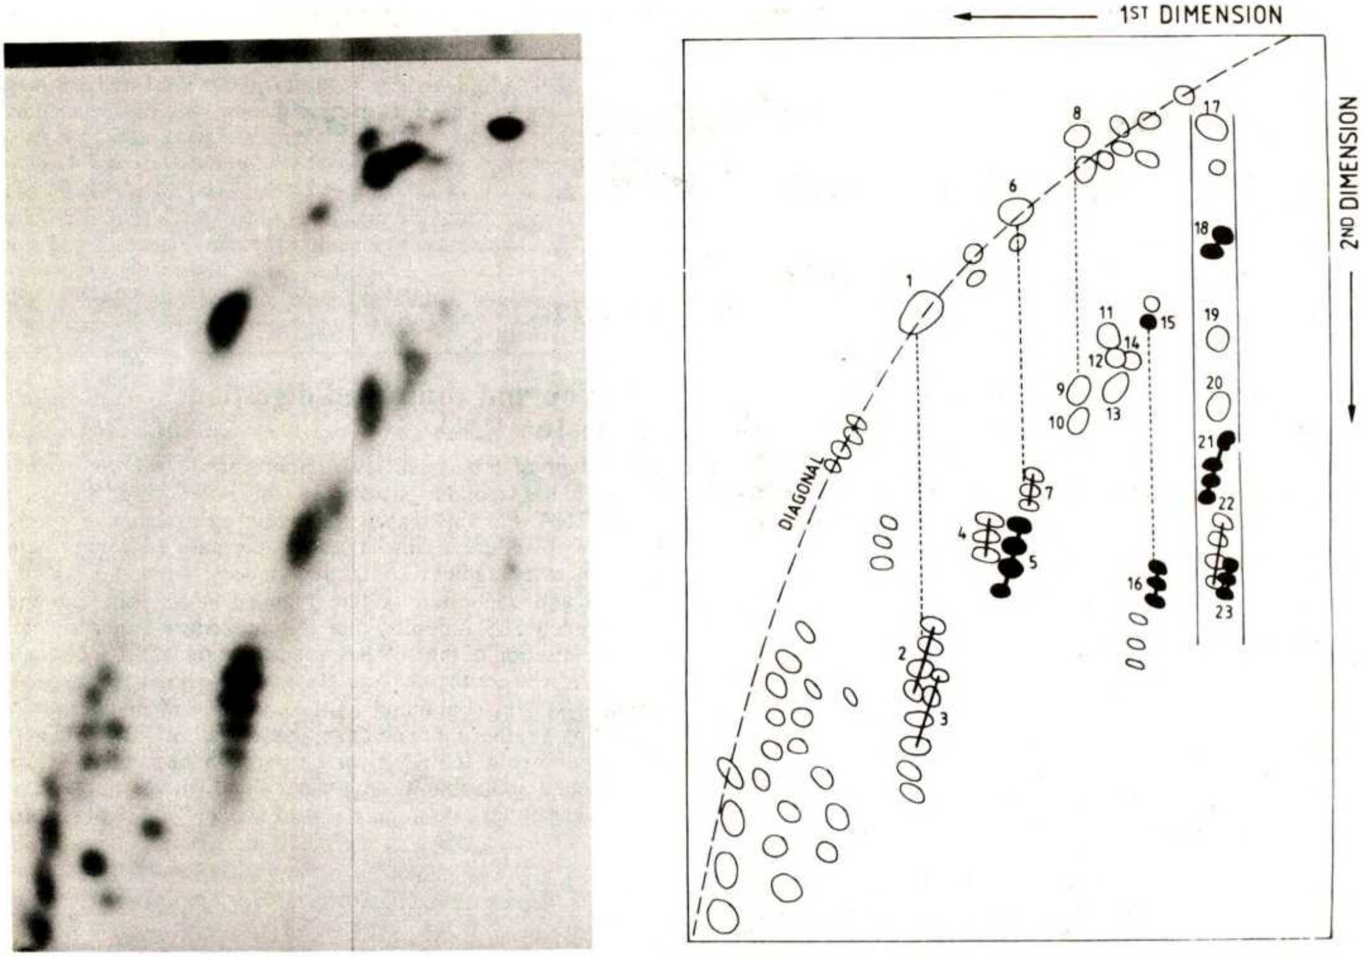

Fig. 2 Two-dimensional separation of EDTA fragments. After proteinase treatment, the S_1-digested RNA (see Fig. 1 legend) was made 6.5 mM in EDTA and then divided into two aliquots which were incubated for 10 min at either 35 or 40 °C, respectively, followed by rapid cooling in ice. The samples were applied to a 5–20% polyacrylamide gradient slab gel (40 cm long), using the dodecyl sulphate–EDTA buffer system described in ref. 13. The gel was run at 0 °C, until a bromphenol blue marker had run 24 cm. The sample strips were autoradiographed and then applied to 20% gels containing urea, using the buffer system of ref. 28. These gels were run at room temperature, until a xylene cyanol marker had run 24 cm. Two gels (15 cm × 40 cm) were needed for each sample strip, and the figure shows the combined autoradiographs of the two gels from the 40 °C sample, with the corresponding autoradiogram from the first dimension superimposed at the top. (A substantial amount of the RNA ran as mononucleotides, not included here.) The key on the right-hand side indicates the numbers assigned to the spots or groups of spots. Groups of spots joined by bars indicate families of identical sequence, deduced from the oligonucleotide analyses (for example, the upper two spots from the fragment group 2 plus 3 contained only the fragment 2 sequence, the lower two spots only the fragment 3 sequence; the poorly resolved spots in the centre contained a mixture of both sequences 2 and 3). Spots shaded in black were either only observed or were much stronger on the gel from the 35 °C sample. Vertical lines indicate sets of related fragments.

and magnesium as were present in the sucrose gradient. Details are given in Fig. 1 legend.

Preliminary tests showed that when the digested RNA was applied to the two-dimensional gel system outlined above, the number of inter-fragment interactions was far too large to permit an analysis; in the first (non-denaturing) dimension most of the RNA ran as multi-component complexes containing many hundreds of bases. It was therefore necessary to introduce a partial denaturing treatment before applying the sample to the gel. This served to simplify the pattern of fragments by destroying most of the weaker interactions (which probably also included some isolation artefacts), leaving only the most stable structures. For this purpose, the digested RNA was first treated with proteinase K to inactivate the nuclease, and was then denatured by warming to specific temperatures in various buffers. After rapid cooling, the sample was applied to the two-dimensional gel system. (Subsequent experiments revealed that the proteinase treatment did not totally destroy the enzyme in our conditions. This fact was advantageous, in that it allowed a further mild digestion of some of the single-stranded fragments released during the denaturing incubation, resulting in a further simplification of the gel patterns; on the other hand, this same effect may be partly responsible for the ragged ends observed in the fragments (see below).)

The gel patterns obtained were very reproducible for a given denaturation treatment, but varied markedly according to the precise conditions used for this denaturation. We will describe the results of two sets of experiments, one in which the sample was denatured in the same magnesium-containing buffer as that used for the nuclease incubation, and the other in which the magnesium was removed by addition of EDTA. The sets of fragments will be referred to as 'magnesium' and 'EDTA' fragments, respectively.

Fragments partially denatured in the presence of EDTA

Figure 2 shows the two-dimensional gel pattern obtained from an S_1 digest of 16S RNA, partially denatured in the presence of EDTA. Precise conditions for the sample preparation and gel electrophoresis are given in the legend. Denaturation was made at either 35 or 40 °C, and the key diagram on the right of Fig. 2 indicates the additional spots which were observed at the lower temperature, as well as those which were present at both temperatures. The figure shows the expected properties, namely, a 'diagonal' consisting of fragments either already denatured or containing uncut loops of secondary structure, together with clear families of fragments lying below this diagonal. (The diagonal is curved as a result of the gradient gel system used for the first dimension.)

^{32}P-labelled RNA fragments were extracted from the gels, digested with T_1 ribonuclease and subjected to oligonucleotide analysis by the classical techniques of Sanger *et al.*[19]. The gel separation was sufficiently good and the background sufficiently low for clean fingerprint data to be obtained in most cases without further purification, and a typical fingerprint (bases 577–615 in the 16S sequence[14]) is shown in Fig. 3. Molarities of the oligonucleotides present were determined from the fingerprint, and their identities were confirmed by digestion with ribonuclease A as described in Fig. 3 legend. The data were then fitted to the 16S sequence of Brosius *et al.*[14], and the fragment analyses from the gels corresponding to both denaturation temperatures (35 and 40 °C) were combined. From these analyses, a picture of the gel pattern in terms of nucleotide sequences could be built up, fragments of identical sequence (but differing in steps of one nucleotide in length) being indicated by the bars joining the spots in Fig. 2. The location in 16S RNA of the sequence corresponding to each numbered spot or group of spots from Fig. 2 is presented in Fig. 5. It is clear from the groups of related spots in Fig. 2 that in many cases the fragments had 'ragged ends', and in addition it was not always possible to localise the 5′ and 3′ ends of the fragments precisely, either as a result of the particular region of the 16S sequence concerned (such as a fragment ending in a run of several G residues), or due to an ambiguity in the identification of the 5′ and 3′ oligonucleotides (which are of the type pXpYpZp and XpYpZ, respectively, after consecutive S_1 and T_1 digestion). Thus, the 5′ and 3′ ends of the fragments as depicted in Fig. 5 should be taken as being approximate to the extent of ±2 bases. In all cases, however, there was excellent agreement between the fingerprint data and the length of the fragment as estimated by its mobility in the second-dimension gel.

Comparison of the data of Figs 2 and 5 shows that the expected fragment relationships appear. For example, fragment 1 (occurring about 600 nucleotides from the 5′ end of 16S RNA) is the sum of fragments 2 and 3, but the latter are not quite contiguous sequences, being separated by a gap of several nucleotides. Further up the gel, a similar situation is found with the larger fragments 6 and 7, from the same region of the RNA, except that in this case (in contrast to spots 2 and 3) the spots containing fragment 7 were a mixture of both halves (denoted 7 and 7′ in Fig. 5) of the sequence contained in fragment 6, again with a gap in the middle. Thus, fragments 2–3 and 7–7′ must be involved in base-paired interactions with one another, and run in the first dimension together with the corresponding uncut loop fragments 1 and 6. The overall pattern of fragments from Fig. 2 will be discussed below, together with the results from the set of magnesium fragments.

Fragments partially denatured in the presence of magnesium

Figure 4 shows the two-dimensional gel pattern obtained after denaturation at 45 or 50 °C in the presence of magnesium. A different gel system was used for the first dimension in this case (see Fig. 4 legend) to keep magnesium present as far as the second dimension, and the acrylamide concentration was also increased to improve the resolution of the smaller fragments. In other respects, Fig. 4 should be interpreted in exactly the same way as Fig. 2. The pattern of fragments is obviously rather more complex in this case, and in some parts of the gel (such as the spots between nos 28 and 29) the fingerprints obtained were mixtures which could not be clearly interpreted. Again, gels corresponding to both denaturation temperatures were analysed, but in this case, for simplicity, the spots on or near the diagonal (with the exception of nos 42 and 48) were not subjected to fingerprinting. It is interesting that RNA prepared by the standard phenol–dodecyl sulphate technique or by acetic acid–urea treatment[20] gave identical gel patterns to that of Fig. 2 after digestion followed by denaturation in EDTA. However, when the digest was denatured in the presence of magnesium, RNA prepared by either of these methods gave patterns resembling that of Fig. 2 more closely than that of Fig. 4.

The results of all the analyses from the gel of Fig. 4 are included in Fig. 5, and the structures which were deduced for the interacting fragments are presented in Fig. 6. Figures 2, 4, 5 and 6 should be considered together in the following discussion, fragments 1–23 arising from the gel of Fig. 2, and 24–50 from that of Fig. 4.

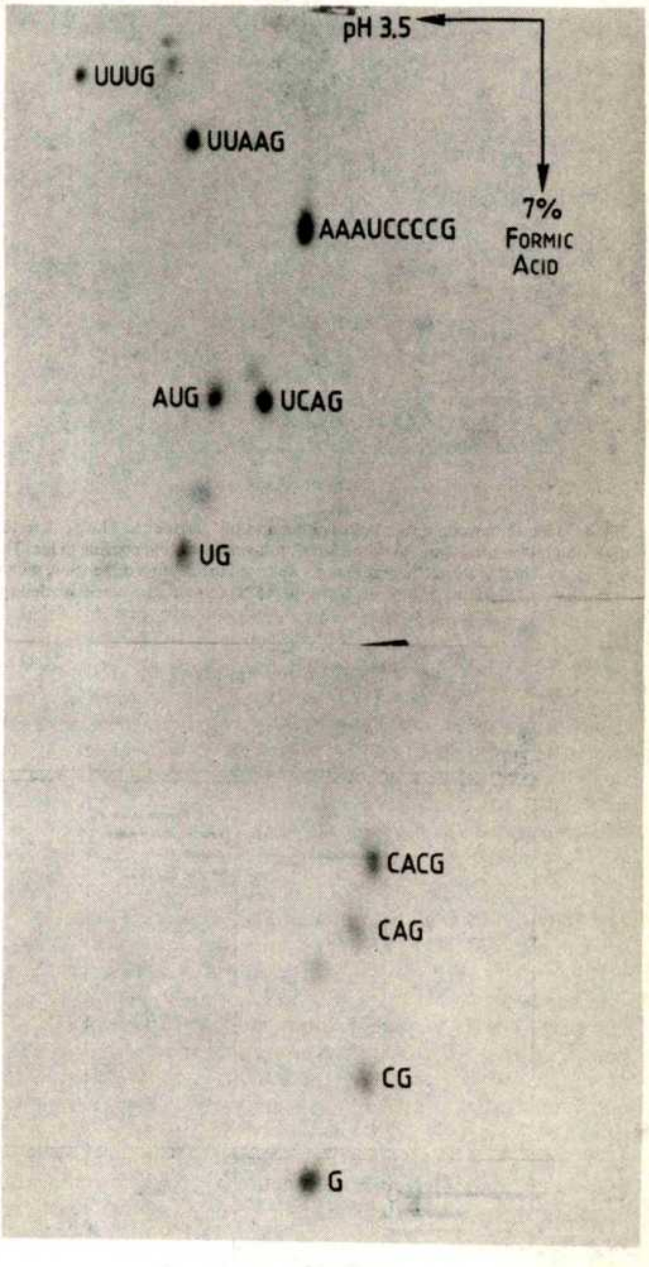

Fig. 3 Example of a T_1 ribonuclease fingerprint. ^{32}P-labelled spots were extracted from the two-dimensional gels (Figs 2 or 4) with phenol and dodecyl sulphate buffer as described elsewhere[25]. Each RNA sample was precipitated from the aqueous layer with ethanol, in the presence of 50 μg carrier RNA, and, after a further ethanol precipitation, was dissolved in 10 μl of 10 mM Tris-HCl, *p*H 7.8, and 1 mM EDTA, and digested with T_1 ribonuclease. Oligonucleotide analysis was made according to the methods of Sanger *et al.*[19] as described elsewhere[25]. The spots were cut from the fingerprints, analysed for radioactivity and subjected to secondary digestion with ribonuclease A as described elsewhere[29], using the two-dimensional separation system of ref. 30. The fingerprint in this case is of bases 577–615 of the 16S RNA sequence[14].

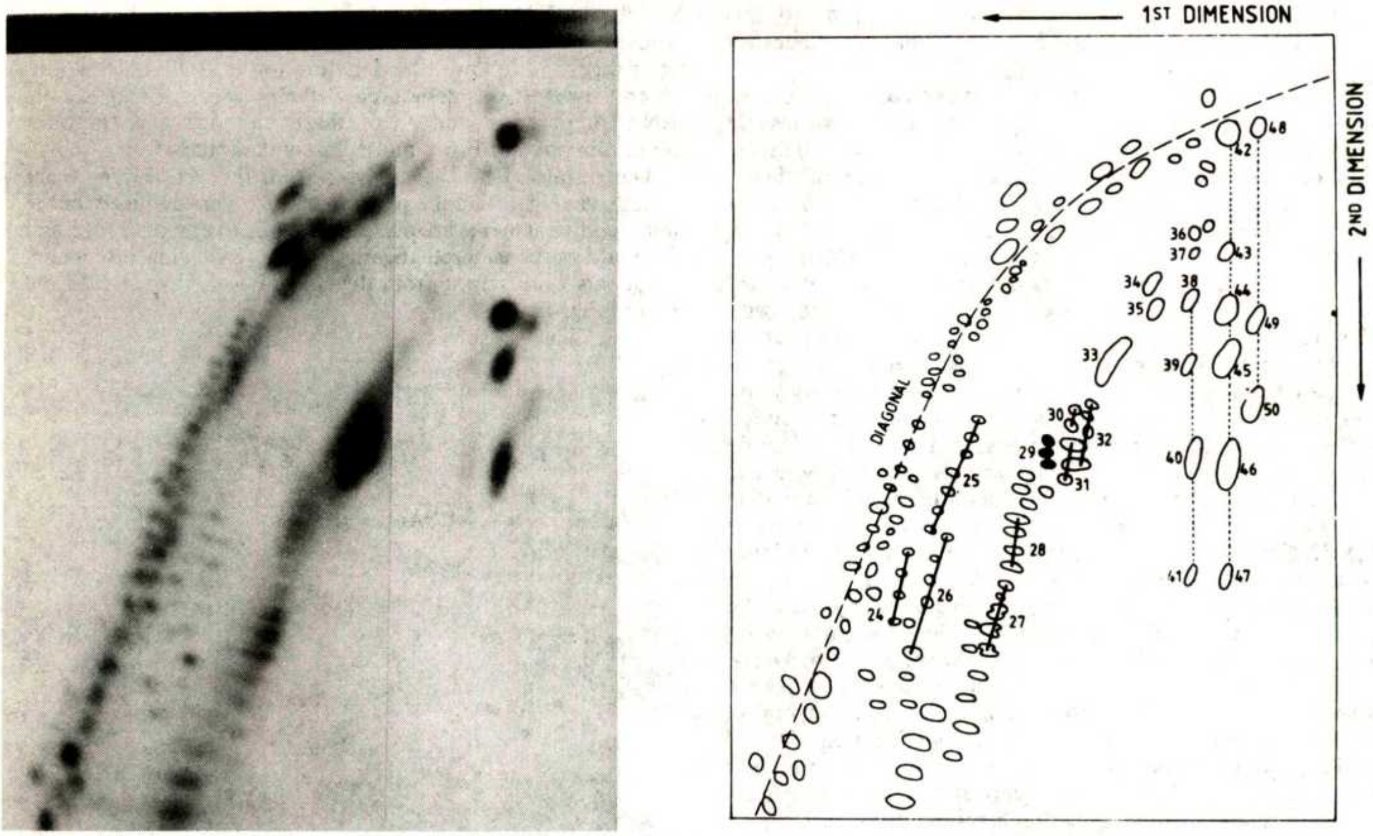

Fig. 4 Two-dimensional separation of magnesium fragments. The S_1-digested RNA (see Fig. 1 legend) was divided into two aliquots which were incubated in the digestion buffer for 10 min at 45 or 50 °C, followed by rapid cooling in ice. The samples were then applied to the two-dimensional gel system as described in Fig. 2 legend, except that a 5–25% gradient gel was used for the first dimension, with 0.3 mM magnesium acetate in place of dodecyl sulphate and EDTA. The figure shows the autoradiographs of the gels from the 45 °C sample, the black-shaded spots (no. 29) being absent in the 50 °C sample. For other details see Fig. 2 legend.

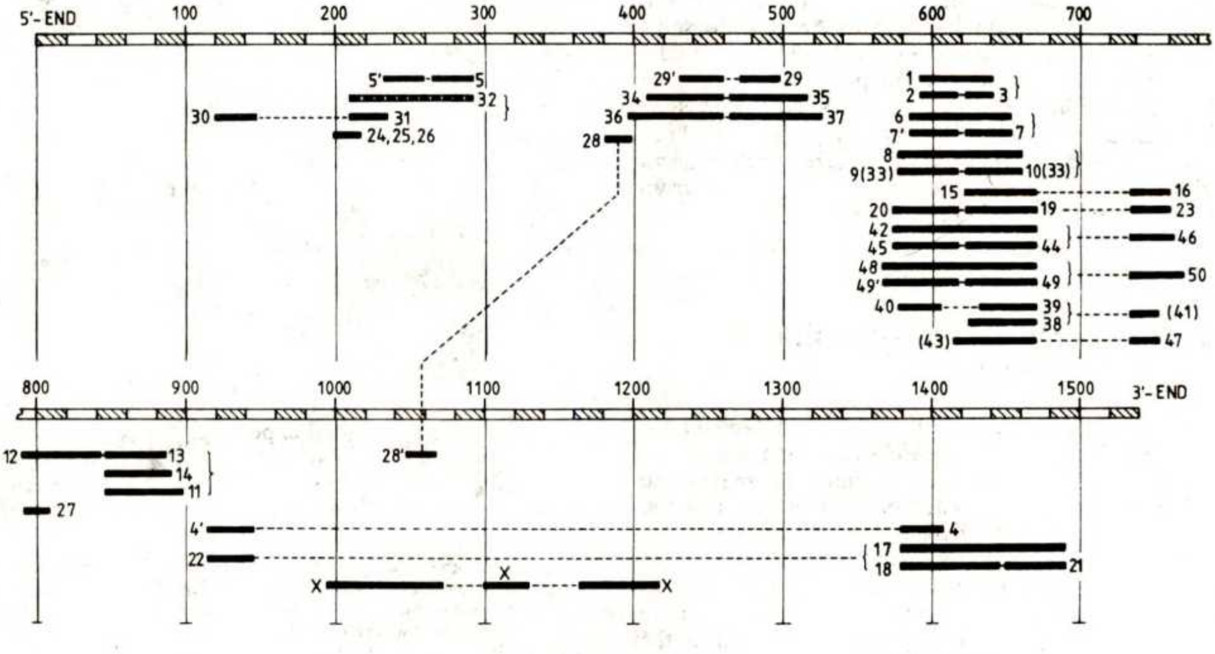

Fig. 5 Location of fragments in the 162 RNA sequence[14]. A scale of nucleotides is given, numbered from the 5' end. Fragment numbers by each sequence (black bars) correspond to those of Figs 2 and 4, and interacting fragments are joined by dotted lines. Sequences such as 29, 29' were found together in the single gel spot with the corresponding number. Fragments bracketed together (for example, 1 and 2, 3) were on the same vertical line in the gel, whereas fragment numbers in parentheses (for example, 33) indicate minor components. Fragment 32 is a special case which (judged from its mobility in the second dimension gel) contained at least three sequences corresponding to fragments 5, 5' and 31. The three fragments marked X were found in earlier experiments using RNA isolated in the presence of EDTA and denatured to 35 °C in the presence of 100 mM NaCl after digestion.

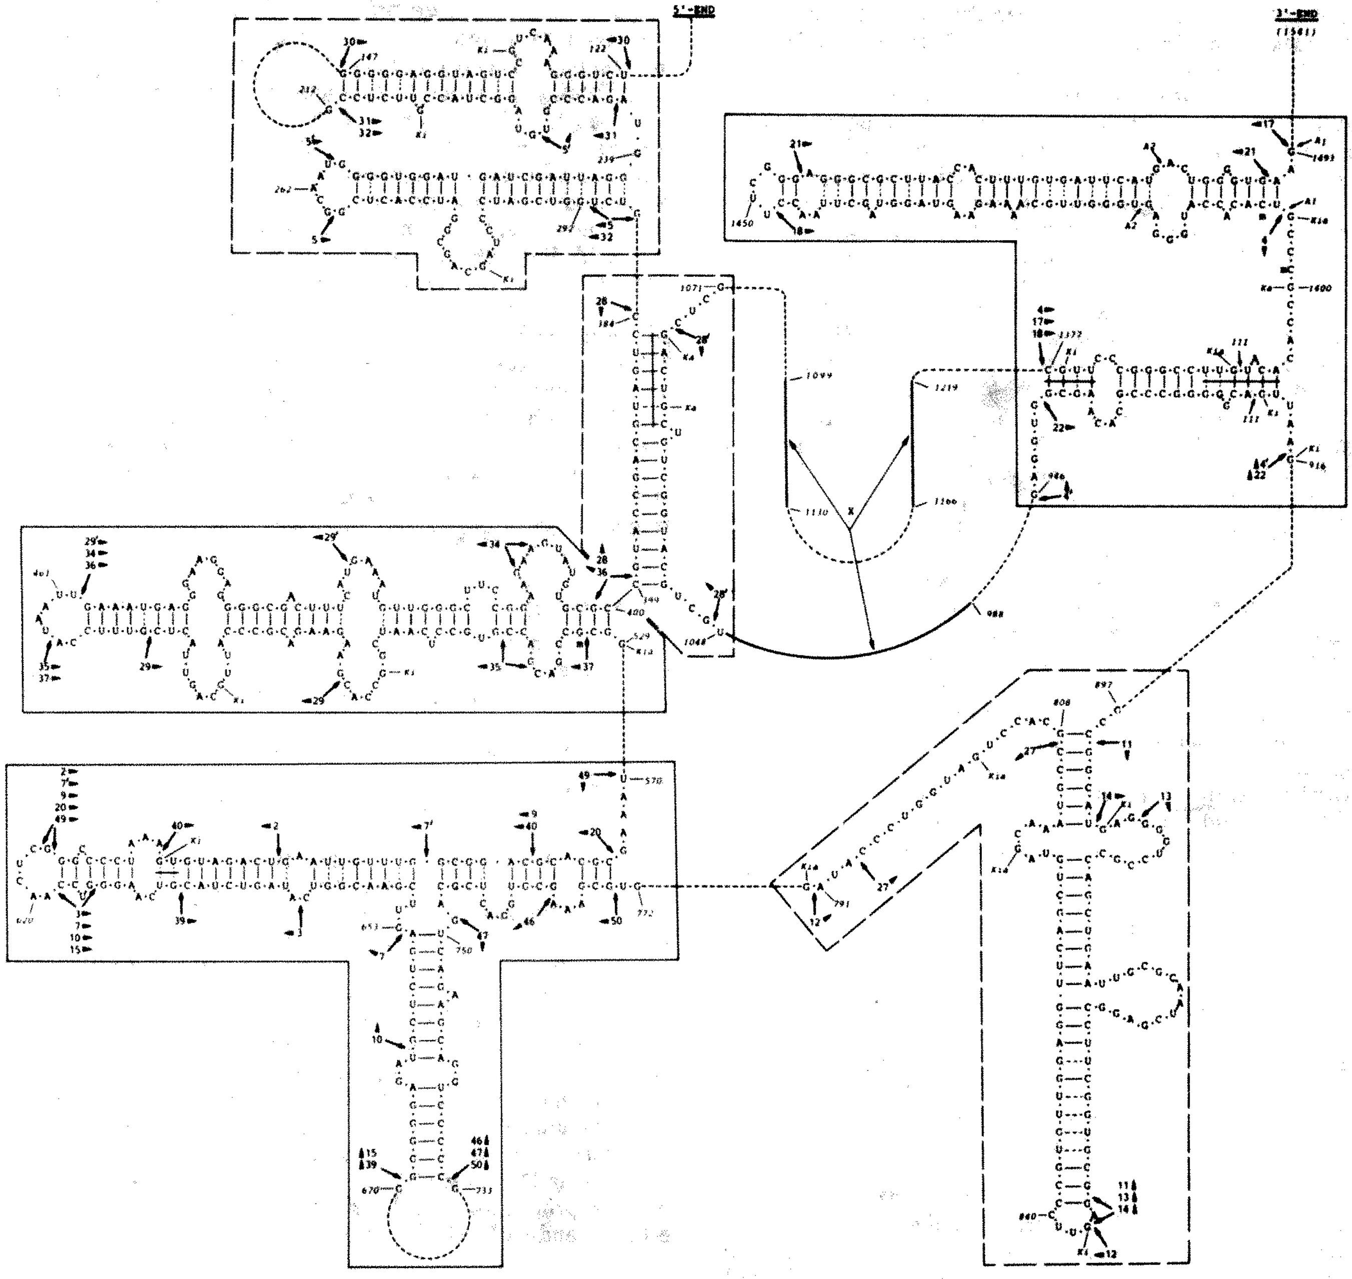

Fig. 6 Secondary structures proposed for the interacting fragments. Numbers in italics indicate the distance in nucleotides from the 5' end of the RNA. Numbers in bold type indicate the approximate 5' and 3' ends of the respective numbered fragments from Figs 2, 4 and 5, with the arrowheads indicating in which direction each fragment runs. The structural domains enclosed by solid lines are regarded as quite certain, whereas those enclosed by broken lines are less certain, for the reasons discussed in the text. Kethoxal sites are indicated by Ki and Ka for sites in inactive[3] or active[1,2] particles, respectively, and bars drawn through base-paired regions (for example, bases 385–390) are where the kethoxal data suggest a single-stranded structure in the 30S subunit. The symbols III, A1 and A2 refer to fragments isolated from the 30S subunit in earlier work[25,26] and the three fragments marked X are involved in a complex interaction (see text).

Interpretation of the sequence data from the sets of interacting fragments

The criteria for interaction between two fragments are that (1) they lie on the same vertical in the gel, (2) they are present in equimolar amounts, and (3) their combined molecular weights are consistent with their mobility as an undissociated complex in the first dimension. The interactions which were deduced are incorporated in Fig. 6 into six structural domains which are surrounded either by solid or broken lines according to the degree of certainty assignable to the various structures drawn for the interactions. Best fits were obtained with the help of a simple computer program. In several cases alternative structures can be drawn which differ in detail without greatly affecting the overall topography of the loops (compare ref. 7). We have selected the possibilities which seem the most likely, but we emphasise that the important feature of our data at this stage is that the sets of fragments provide a sound experimental basis for determining those regions of the RNA which are somehow involved in interactions with one another. Note that the data agree well with the sites of kethoxal modification of RNA in the 30S subunit[1–3]; these sites are included in Fig. 6.

The simplest case to consider is the set of fragments between bases 400 and 500 (Fig. 5), consisting of the fragment pairs 29–29', 34–35 and 36–37. This set forms a clear 'pyramid' of fragments of increasing length, which can be drawn as the rather symmetrical structure shown in Fig. 6, remembering (as already mentioned) that the 5' and 3' ends of the fragments were not always precisely definable. Fragments corresponding to the shortest base-paired regions (bases 450–460 and 465–475) were not found; such small fragments would have run on the gel below fragments 24–27 (Fig. 4), an area which was too complex to interpret. In this context, remember also that S_1 nuclease does not attack all apparently single-stranded regions in RNA (for example, in tRNA only the anticodon loop is cut[21]).

Immediately adjacent to the structure just discussed, there is a strong long-range interaction of 15 base pairs, defined by the fragment mixture 28–28′. The structure is assigned as tentative in Fig. 6 because, although the interaction was reproducibly detected and the fingerprint data were clear, the sequences concerned have not so far been observed in larger fragment structures where each component of the interaction could be observed separately. In this case, the kethoxal sites suggest that the weaker half of the structure is opened up in the 30S subunit; such a situation would be consistent with the finding that the RNA has a lower helical content in the subunits than in the isolated form[22].

The structures drawn for the interactions in the regions between bases 100–300 and 800–900 are also assigned as tentative. In the latter case, the interacting fragments 12 and 11 or 13 were reproducibly found, but the presence of fragment 14 without a 'partner' (Fig. 2) suggests that the 5′ half of this loop (fragment 12) is easily digested to smaller pieces which were not analysed in the experiment of Fig. 2. The structure proposed for this interaction has a single-stranded 'tail' at the 5′ end (again suggesting a missing piece), this arrangement being supported by the finding of precisely this tail as an unpartnered fragment (no. 27) in Fig. 4. In the region of bases 100–300, a simple loop structure could be drawn for bases 231–296, containing the interacting fragments 5 and 5′ (Fig. 2). However, the sequence of fragment 5′ overlaps that found for fragment 31 (Fig. 4) by several bases, the latter fragment clearly interacting with fragment 30. An interaction similar to that between 5 and 5′ was nevertheless also present in the gel of Fig. 4, as evidenced by spot 32, whose fingerprint indicated a mixture of the sequences contained in fragments 5, 5′ and 31. In this context, the significance of the small fragments (24, 25 and 26, Fig. 4), which overlap fragment 31 and extend it in the 5′ direction, is not clear.

The most detailed information was obtained from the region of bases 550–800. For simplicity, only selected fragments are indicated in Fig. 6, and the reader should refer to Fig. 5 for fragments of similar or identical sequence (for example, fragment 15 is the same as nos 19, 44, 49 and 38). As already mentioned, the interacting fragments 2–3 and 7–7′ clearly define the loop structure of bases 587–653. The next pair of fragments (9 and 10) can be drawn as a simple base-paired extension to this structure, but the families of larger fragments contradict this simple extension. Fragments 44, 45 and 46 (Fig. 4) reproducibly showed the presence of an extra piece of RNA (bases 733–764), which must be involved in the structure, and fragments 49, 49′ and 50 indicate a further elongation in the extreme 5′ and 3′ directions. The interaction between the three fragments is accordingly represented by the structure shown in Fig. 6, and other minor components of the gels from this RNA region are consistent with the structure. For example, fragments 39, 40 and 41 appear as a family in which both the left and right ends of the structure are missing (Fig. 6), and fragments 42 and 48 correspond to uncut loops running approximately from bases 570 to 670. Fragments 15 and 16 (Fig. 2) are also consistent, although here a piece of RNA must be 'missing' from the analysis to account for the mobility of the complex in the first gel dimension. Note also that this structure agrees exactly with the secondary structure of part of this region proposed by Müller *et al.* for the RNA binding site of proteins S8 and S15 (ref. 23).

Fragments 44, 45 and 46 (Fig. 4) were identical to fragments 19, 20 and 23 (Fig. 2), respectively. In the latter case, fragment 23 disappeared at the higher temperature (40 °C, Fig. 2), allowing the complex between 19 and 20 to run slightly faster in the first dimension. This enabled the complicated region at the right-hand side of Fig. 2 to be resolved, as it follows that fragments 19, 20 and 23 form one family, and 17, 18, 21 and 22 another (Fig. 5). These fragments suggested the long-range interaction between bases ~920–940 and 1,380–1,400, an interaction which was very precisely and reproducibly confirmed by fragments 4 and 4′ (Fig. 2). This is probably the same interaction as that proposed (but not localised) by Ehresmann *et al.*[24], although as with the other long-range interaction already discussed the distribution of kethoxal sites suggests that the weaker ends of the base-paired structure are open in the ribosome. This structure also fits well with the 5′ and 3′ ends of the RNA from ribonucleoprotein 'fragment III', isolated from the 30S subunit[25], and encompasses a complex interaction between the RNA fragments named 'X' from this region. The latter fragments were found in earlier experiments, but can be arranged together in too many different ways to merit drawing a structure at this stage. The remainder of the region (bases 1,400–1,500) can be drawn as a simple loop structure, fragment 17 (lying just below the diagonal) representing the uncut loop together with the tail interacting with fragment 22, whereas fragments 18 and 21 represent the corresponding loop halves, which disappeared at the higher temperature (Fig. 2). This structure also agrees well with the sequences of two RNA fragments (denoted A1 and A2) which were isolated from the 30S subunit[26].

Conclusion

The experiments described here offer a basis for determining the secondary structure of ribosomal RNA. Although the data were obtained from isolated RNA, in general they are in good agreement with other data from the 30S subunit, in such cases where a comparison is possible. There are, however, some anomalies, suggesting structural heterogeneities in the RNA. Such heterogeneities could reflect multiple coexisting structures *in vivo*, or may represent artefacts introduced by the isolation procedure. Experiments now in progress, using the 30S subunit as starting material as well as RNA isolated by various methods, should help to resolve this aspect of the problem. At the same time it cannot yet be entirely excluded that some conformational rearrangements occur during the partial denaturation treatment of the digests, but this should become clearer as the data accumulate. We believe that the further development and application of this approach should lead not only to a reasonably accurate experimental model of the ribosomal RNA structure both within the subunits and as an isolated moiety, but also to an understanding of the relative stabilities of the individual parts of the structure and their dependence on ionic environment.

We thank Dr C. Zwieb for helping us with the large numbers of fingerprints, Mr J. Schuerman for writing the computer program and Dr H. G. Wittman for advice and encouragement.

Two-step binding of eukaryotic ribosomes to brome mosaic virus RNA3

Paul Ahlquist, Ranjit Dasgupta, Ding S. Shih, David Zimmern & Paul Kaesberg

Biophysics Laboratory of the Graduate School, and Biochemistry Department of the College of Agricultural and Life Sciences, University of Wisconsin-Madison, Madison, Wisconsin 53706

Although brome mosaic virus RNA3 has only one translatable cistron, it can bind two 80S ribosomes at initiation. One ribosome binds at the first AUG codon (bases 92–94). The other binds nearer the 5′ end at an entry or holding site. Disome formation is thus unrelated to a silent cistron ~1,000 bases downstream.

ALTHOUGH the messenger-sense genomic RNAs of many viruses infectious to eukaryotes encode several cistrons, only the 5′ proximal cistron of each such RNA is translatable[1]. Translation in eukaryotes is generally considered to be restricted to 5′ terminal cistrons by initiation requirements for a distinctive RNA sequence and a 5′ terminal blocking group—the cap. However, sequences preceding coding regions show no obvious common features[2] and the cap itself is dispensible[3]. Removal of the cap reduces the rate but not the specificity of initiation[4], and several viral mRNAs have been found that are not capped. Moreover, eukaryotic ribosomes are capable of recognising internal cistrons on uncapped prokaryotic mRNAs[5], although it is possible that such RNAs may have been modified by enzymes existing in the cell-free extracts. The characteristics that define a functional eukaryotic ribosome binding site and prevent such a site from occurring internally in the RNA thus remain undetermined.

We have examined these issues as they apply to the brome mosaic virus (BMV) RNAs. BMV is a small, icosahedral virus of cereal plants. Much is known about the location of the BMV coding regions and their translation. The BMV genome consists of three distinct RNA molecules (designated RNA1, RNA2 and RNA3 in decreasing order of size) encapsidated in three virions[6]. These RNAs are necessary and sufficient for infectivity, but virions containing RNA3 (2,200 bases) also contain one copy of a subgenomic RNA designated RNA4 (900 bases). RNA3 contains the nucleotide sequences and genetic information of RNA4, and can act as a precursor to RNA4 found in progeny viruses resulting from infection with RNAs 1, 2 and 3 alone. *In vitro* translation experiments show that RNA4, although dispensible for infectivity, is the functional mRNA for the viral coat protein. The only translation product detectable when BMV RNA3 is used as a template in optimal conditions is a polypeptide (MW 35,000) unrelated to coat protein (MW 20,000)[7]. Thus RNA3 contains at least two cistrons—an accessible cistron and a coat protein cistron which for some reason is inactive. Subsequent experience has shown that similar genomic RNAs containing one or more untranslatable coding regions, plus their accompanying subgenomic RNAs, which are active messengers, are common in viral systems[1]. The untranslatable coding regions of these genomic RNAs are now popularly called silent cistrons.

During our experiments we observed that, in cell-free extracts of wheat embryo, two ribosomes can bind to RNA3 in conditions where initiation can proceed but elongation is inhibited. In identical conditions RNA4 binds only monosomes. Originally it was considered possible that the binding of two ribosomes was related to the dicistronic organisation of BMV RNA3. However, BMV RNAs 1 and 2 also bound two ribosomes and they, as well as RNA4, are thought to be monocistronic messengers[7]. In fact, the binding of two ribosomes in similar circumstances has been observed with several viral RNAs including tobacco mosaic virus genomic RNA[8], alfalfa mosaic virus RNA3[9], and encephalomyocarditis virus RNA (our observation). As these RNAs differ considerably in their organisation and structural features, it seemed likely that some rather subtle structural feature common to all these viral RNAs was responsible for disome formation, and that this might be important both to the reproduction of the virus and to the mechanism of protein synthesis. Accordingly, we studied ribosome binding to RNA3 using procedures designed to reveal features of the nucleotide sequence involved in disome formation.

Ribosomal binding to RNA3 and to 5′ terminal fragments of RNA3

Two ribosomes bound to one molecule of ^{32}P-labelled BMV RNA3 when translational elongation was blocked by sparsomycin[10] anisomycin[11] or T2 toxin[12] used singly or in combination (Fig. 1*a*). (T2 toxin, a derivative of 12,13-epoxytrichothecene, inhibits the formation of the first dipeptide bond but has no effect on the formation of 80S initiation complexes.) In all cases in which ribosomes were present in excess, the amount of labelled RNA present in structures sedimenting at the rate of disomes exceeded that sedimenting as monosomes by at least a factor of two. In Fig. 1*a* the smaller peak of radioactive RNA coincided with the peak of UV absorbance due to 80S ribosomes. The larger peak co-sedimented with the disome peak from polysome profiles run in parallel gradients. We observed similar patterns with BMV RNAs 1 and 2 (data not shown), but not with BMV RNA4 (Fig. 1*b*), which presented only a single peak of RNA radioactivity associated with monosomes.

Although the binding experiments above were done with uniformly labelled RNA, for ease in correlation with sequence analysis it is convenient to use terminally-labelled RNA. We chose to label BMV RNA3 at its 5′ end with the capping enzyme from vaccinia virus cores described by Moss and co-workers[14]. This enzyme transfers a GMP moiety from GTP to 5′-diphosphorylated RNA termini and then, in the presence of *S*-adenosyl methionine, methylates the resulting inverted G residue and the 5′ terminal ribose of the chain proper. When partially purified, the enzyme is associated with a 5′-triphosphate γ-phosphatase. It has the important feature that it regenerates the natural 5′ terminal configuration of capped messenger RNA. The reconstructed 5′ end does have a ribose methylation lacking in the original BMV RNA, but this has been shown to have little effect on protein synthesis[16]. The enzyme has three other advantages over polynucleotide kinase, the enzyme most frequently used for 5′ labelling RNA. First, despite the fact that decapped and dephosphorylated BMV RNA3, like some other eukaryotic mRNAs[17], is an extremely poor substrate for polynucleotide

0028–0836/79/390277—06$01.00

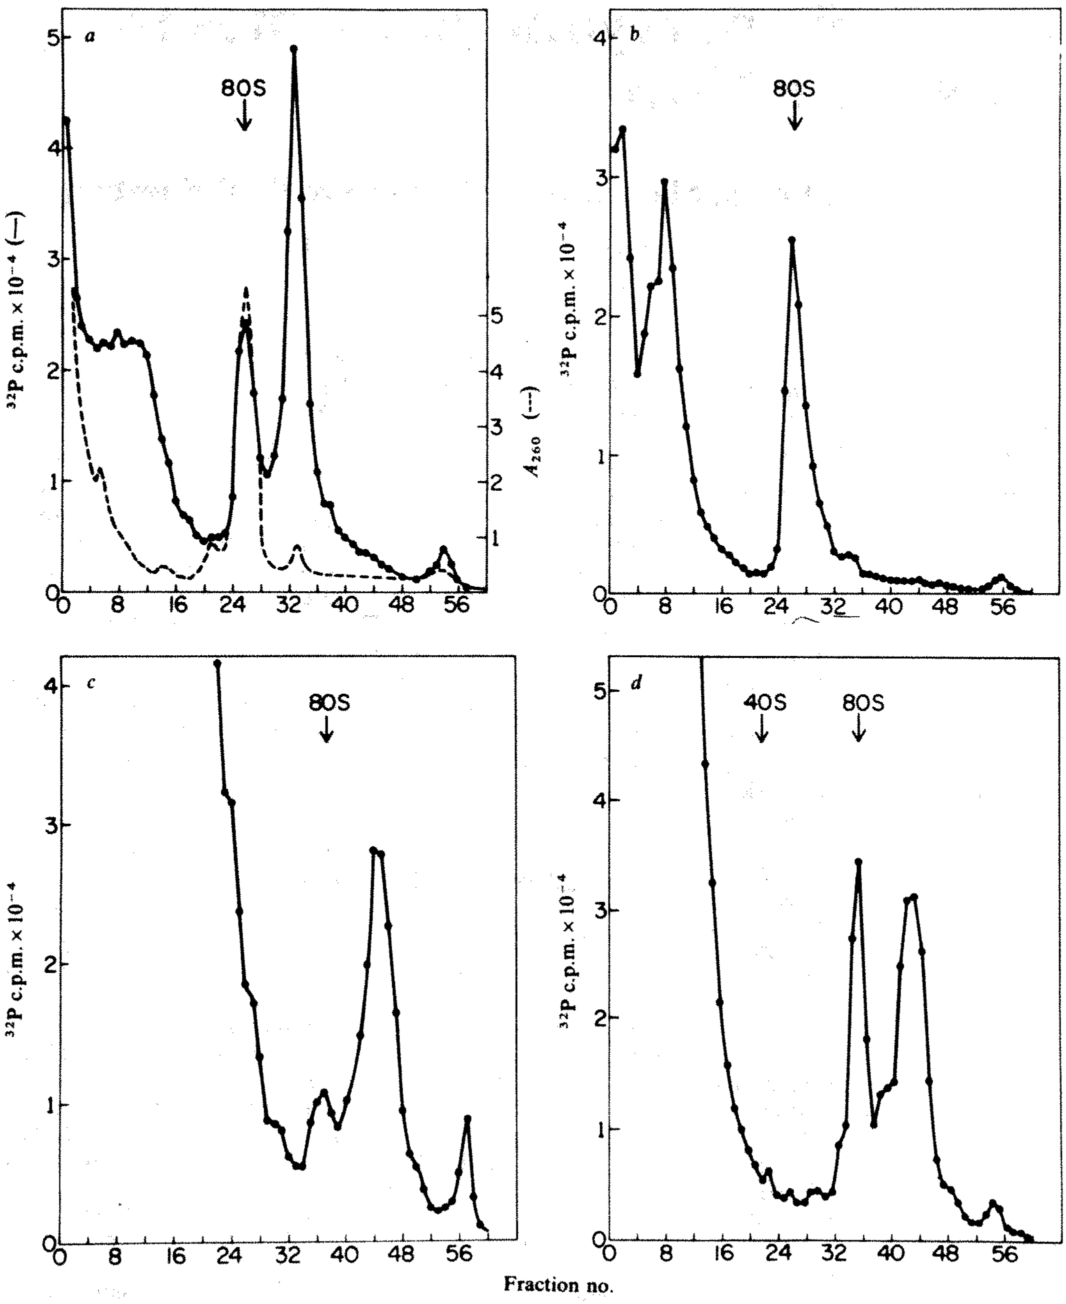

Fig. 1 Detection of the binding of two ribosomes to RNA3 by sucrose density gradient sedimentation analysis. Preparation of wheat embryo extracts and ^{32}P-uniformly labelled BMV RNA components were as previously described[13]. Terminal labelling with the vaccinia capping enzyme[14] was carried out in a 50 μl reaction mix containing 20 μg decapped BMV RNA3, 20 μM [α-^{32}P]GTP (480 Ci mmol^{-1}, Amersham), 0.16 mM ATP[15], 50 μM *S*-adenosyl methionine, 50 mM Tris-Cl *p*H 7.8, 1 mM $MgCl_2$, 1 mM DTT and 5 μl of DEAE-cellulose purified enzyme preparation. The reaction mix was incubated for 15 min at 37 °C, phenol extracted twice, ether extracted twice, and ethanol precipitated. Conditions for ribosome binding reactions (100 μl) were as described elsewhere[13] except that the creatine phosphokinase concentration was 20 μg ml^{-1} instead of 125 μg ml^{-1}. The reaction mixtures were incubated with 0.45 mM anisomycin plus 0.06 mM T2 toxin (*a* and *b*) or wiith 0.2 mM sparsomycin (*c* and *d*) for 5 min followed by addition of ^{32}P-labelled RNAs and further incubated for 10 min. The reaction mixtures were cooled on ice and applied onto 10–40% sucrose density gradients prepared 50 mM Tris-HCl, *p*H 7.6, 50 mM KCl and 4 mM Mg-acetate. The gradients were centrifuged in a Spinco SW41 rotor at 36,000 r.p.m. for 3 (*a* and *b*) or 4 h (*c* and *d*) and fractionated with an ISCO gradient fractionator. *a*, 5 μg ^{32}P-uniformly labelled RNA3; *b*, 10 μg ^{32}P-uniformly labelled RNA4; *c*, 5 μg ^{32}P-terminally labelled RNA3; *d*, 5 μg ^{32}P-terminally labelled RNA3, partially digested with RNase T_1 as described in Fig. 2, phenol and ether extracted, and ethanol precipitated before ribosome binding. The increase in ^{32}P counts at the top of the gradients shown in *c* and *d* compared to *a* and *b* is due to the presence of unincorporated [α-^{32}P]GTP from the labelling reaction.

kinase, the vaccinia enzyme consistently gave high incorporations of ^{32}P. Second, even our partially purified preparation was comparatively free of RNAse. Third, as the enzyme recognises only 5′ di- or tri-phosphorylated ends, it does not label internal nicks in the RNA. Figure 1*c* shows that BMV RNA3, decapped by periodate oxidation and β-elimination, then recapped with the vaccinia capping enzyme and [α-^{32}P]GTP in the presence of *S*-adenosyl methionine, binds to wheat embryo ribosomes in conditions of sparsomycin inhibition in a manner similar to that of uniformly labelled RNA3.

Fragments of terminally-labelled BMV RNA3, partially digested with nucleases, also bind two ribosomes in the presence of sparsomycin. Figure 1*d* shows the binding pattern of a partial RNase T_1 digest of 5′ labelled, capped and methylated RNA3 in conditions of sparsomycin inhibition. Partial RNase ϕ1 digests show a similar pattern. Preliminary experiments showed that the size of these fragments was well within the range of high-resolution sequencing gels, so in further experiments we used partial digestion conditions that gave relatively uniform cleavage of every susceptible site over the first few hundred residues and allowed us to pinpoint the parts of the RNA responsible for binding. For detailed analysis of these experiments we needed to determine the 5′ terminal sequence of RNA3.

5′ Terminal sequence of BMV RNA3

The sequence of the first 164 residues beyond the capping group $m^7G^{5'}ppp^{5'}G$ was determined by rapid gel methods using base-specific ribonucleases[18,19] as shown in Fig. 2. We determined the first few residues from the 5′ terminus independently by partial digestion with nuclease P_1 followed by mobility shift analysis using two dimensional cellulose acetate electrophoresis and homochromatography[21] to allow unambiguous counting of the bases and to confirm the sequence of the extreme 5′ end. The sequence is shown in Fig. 3.

On initial sequencing gels, pyrimidine assignments were made by examining the RNase ϕ1 cleavage pattern on each side of the base in question. Contrary to the published dinucleoside hydrolysis frequencies[22] but in agreement with other observations[23] we found that some A—C bonds (those between residues 12-13, 53-54, 99-100, 131-132, and 141-142) were resistant to RNase ϕ1 cleavage in our conditions. In later gel sequencing experiments RNase Phy M was used to distinguish between C and U residues. RNase Phy M, which cleaves after A and U residues (H. Donis-Keller, personal communication), has a much simpler base specificity than RNase ϕ1 and thus provides a more accurately interpretable cleavage pattern.

RNA fragments associated with monosomes and disomes

5′ End-labelled RNA fragments recovered from the monosome and disome regions of sucrose gradients such as that shown in Fig. 1*d* were freed of protein by phenol extraction and electrophoresed on a sequencing gel in parallel with samples of the original digests that had not been bound to ribosomes (Fig. 4, lanes *c–h*). As a second set of controls, full length RNA3 was recovered from disomes and then digested and electrophoresed

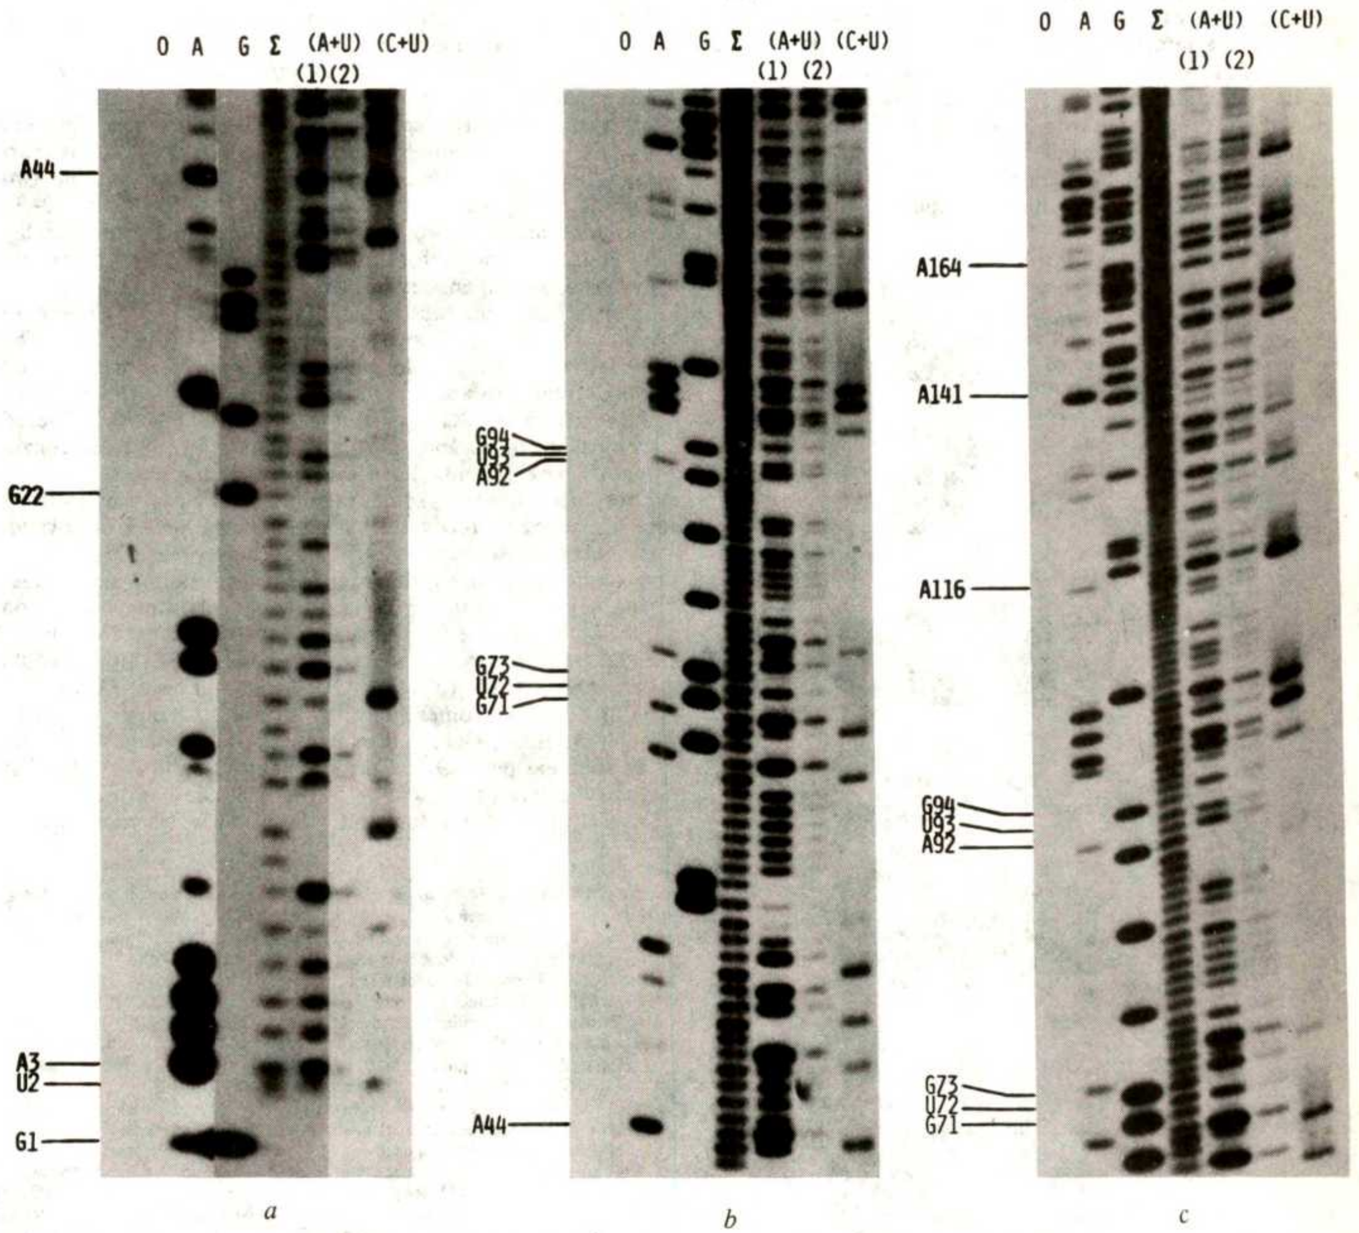

Fig. 2 Sequencing gels of 5′-labelled BMV RNA3. BMV RNA3 was 5′-labelled as described in Fig. 1, except that *S*-adenosyl methionine was omitted. Full-length labelled RNA was isolated on a 5% acrylamide 7 M urea slab gel. Enzyme digests and a minus enzyme control each contained 2.5 μg RNA in 10 μl 20 mM Na-citrate *p*H 5.0, 1 mM EDTA, 7 M urea (ultrapure urea solutions were deionised with Fisher Rexyn I-300 resin before use). Digests were incubated 15 min at 50 °C, after which 2.5 μl of 0.3% xylene cyanol, bromphenol blue, 10 mM EDTA in formamide was added to each. Two different strength digests were done for each enzyme. For RNases U2, T1, and pancreatic RNase, like enzyme digests were mixed together after incubation. For formamide digestion 5 μg of RNA in 20 μl 90% formamide, 10% double-distilled H_2O was incubated 45 min at 100 °C. An aliquot of 2 μl formamide/dye mix was then added. Samples were heated for 1 min at 100 °C and 2 μl aliquots of each were loaded onto freshly polymerised 20 × 40 × 0.035 cm 7 M urea slab gels[20] and electrophoresed at 30–35 mA in 87.5 mM Tris-borate *p*H 8.3, 2.75 mM EDTA. *a*, Shows a 12% acrylamide gel and *b* and *c* show 8% acrylamide gels. Gels were autoradiographed at −70 °C with an unflashed Kodak X-Omat R film clamped tightly between the gel and a Dupont Cronex Lightning Plus intensifying screen. The following symbols are used to designate the various lanes: O, minus enzyme control; A, 2.0, 0.2 units RNase U2 (Calbiochem) per μg RNA; G, 0.04, 0.004 units RNase T1 (Calbiochem) per μg RNA; Σ, formamide digest; A + U(1), 0.08 arbitrary units RNase Phy M per μg RNA; A + U(2), 0.008 arbitrary units RNase Phy M per μg RNA; C + U, 2×10^{-4}, 2×10^{-5} μg pancreatic RNase (Worthington) per μg RNA.

Fig. 3 The nucleotide sequence of the 5′ terminal 164 bases of BMV RNA3. The first AUG and GUG codons from the 5′ end are boxed and nonsense codons are underlined. The amino acid sequence of the protein which would result from initiation at the first AUG is aligned with the nucleotide sequence. Extra N-terminal amino acids which would result from initiation at the first GUG are shown in parentheses.

(Fig. 4, lanes *a* and *b*). The resulting band patterns correspond exactly to those obtained by digestion of RNA3 not exposed to wheat embryo extracts (Fig. 4, lanes *e* and *h*, or Fig. 2), thus excluding the possibility that the ribosome binding behaviour we observe is an artefact of sequence rearrangement (that is, RNA splicing) in the wheat embryo extracts.

A distinct difference in length distribution was observed between RNA recovered from monosomes (Fig. 4, lanes *d* and *g*) and that recovered from disomes (Fig. 4, lanes *c* and *f*): the monosome peak contained fragments 29 to 91 residues long while the disome peak contained fragments 94 residues and longer, as well as faint traces of fragments 69 to 91 residues long (see Fig. 4 legend). The striking transition in ribosome binding properties occurring with fragments of 94 bases or longer is clearly seen on the autoradiogram as a lateral switch in the band pattern from the monosome to disome lanes.

The fact that RNA3 can bind two ribosomes efficiently, but no more than two when translation is inhibited implies that RNA3 has two sites that interact strongly with ribosomes. Efficient disome formation with 5′ terminal fragments of RNA3 as short as 94 residues and failure of shorter fragments to bind two ribosomes implies that one site is near base 94. Bases 92–94 comprise the first 5′ proximal AUG codon, which is presumably an initiation codon for protein synthesis. These bases are followed by an open reading frame as far as the known sequence extends; the other two reading frames are closed by nonsense codons following almost immediately after the AUG. The second ribosome on 94 long fragments, and thus presumably on longer fragments and on intact RNA, must be on the 5′ side of the AUG codon. As fragments 29 residues long are recovered from monosomes and shorter fragments are not, the region around base 29 must have the potential for interaction with ribosomes. However, some fragments in the range of 35 to 60 residues long are recovered from monosomes only in poor yield, possibly because the base 29 binding site may be buried by RNA secondary structure in fragments 35 residues long and longer (see below). Another potential site for ribosome interaction exists around base 70 corresponding to fragments which are again recovered from monosomes in good yield. This site would be in the vicinity of the first GUG codon at bases 71–73. The failure to form trisomes indicates, however, that on intact RNA3 stable ribosome binding does not occur simultaneously at both the site near base 29 and the site near base 70. We infer that ribosome interaction at one of the sites may be transient or sterically hindered. Consistent with this view, fragments 69–91

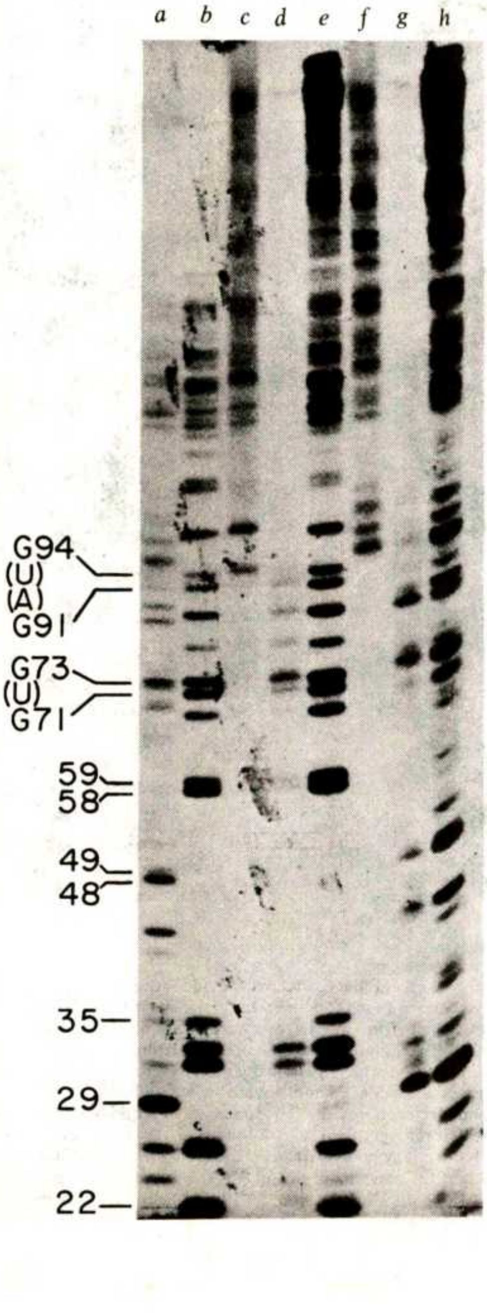

Fig. 4 Analysis of 5′ terminal BMV RNA3 fragments bound in monosomes and disomes. Terminal labelling, ribosome binding, and sucrose density gradient sedimentation were as described in Fig. 1. RNA bound to ribosomes was recovered from sucrose density gradients by pooling the desired fractions, adding 120 µg of wheat embryo ribosomes to pooled disome fractions, and ethanol precipitating the ribosome–mRNA complexes. Precipitates were suspended in 0.1 ml of 0.1 M Tris-HCl *p*H 7.6, 0.2% SDS, and extracted with 0.2 ml of water-saturated phenol. RNA was ethanol precipitated from the aqueous phase. Partial RNase digestions were performed as described in Fig. 2, except that urea was omitted from digests with RNase ϕ1, and were phenol extracted once and ether extracted twice before the RNA fragments were ethanol precipitated. The following samples of 5′ ^{32}P-labelled BMV RNA3, each in 10 µl of 8 M urea, 0.05% xylene cyanol, bromphenol blue were co-electrophoresed at 25 mA on an 8% acrylamide, 7 M urea slab gel (20×40×0.2 cm) in 87.5 mM Tris-borate *p*H 8.3, 2.75 mM EDTA: *a*, One half of the RNA3 recovered as full-length molecules from the disome peak shown in Fig. 1*c*, digested subsequently with RNase ϕ1. *b*, One half of the RNA3 recovered as full-length molecules from the disome peak shown in Fig. 1*c*, digested subsequently with RNase T1. *c*, RNAse T1 fragments recovered from the disome peak shown in Fig. 1*d*. *d*, RNase T1 fragments recovered from the monosome peak shown in Fig. 1*d*. *e*, An aliquot of the RNase T1 digest used for the gradient shown in Fig. 1*d*, saved before binding to ribosomes. *f*, RNase ϕ1 fragments recovered from the disome peak of a gradient analogous to that shown in Fig. 1*d*. *g*, RNase ϕ1 fragments recovered from the monosome peak of the gradient discussed in *f*. *h*, An aliquot of the RNase ϕ1 digest used for the gradient discussed in *f*, saved before binding to ribosomes. Long exposures of the gel shown reveal the presence of bands corresponding to fragments 69–91 residues long in lanes *c* and *f*.

bases long can form disomes, but only inefficiently, confirming that one of the two sites is poor at binding ribosomes stably.

The method above, by examining an entire set of overlapping fragments simultaneously, permits detailed analysis of the contribution of the mRNA sequence to ribosome binding. By use of suitable end-labelling techniques, this method should be generally applicable to other mRNAs, both capped and noncapped. However, it must be recognised that the nucleotide sequences of fragments may fold differently from their counterparts in intact RNA and thus their binding may be different. We have tried to evaluate the steric effect of secondary structure by systematically examining possible folding by computer. We think that it is unlikely to have affected the transition from monosome formation to disome formation between fragments 91 and 94 residues long. The onset of unfavourable secondary structure may explain however why certain 5'-terminal fragments fail to bind stably in monosomes. For example, while fragments 29, 32 and 33 residues long bind well as monosomes, the fragment 35 residues long binds poorly. The 3' end of the 35 residue long fragment can form a small base-paired stem which is at the threshold of stability (Fig. 5*a*). Fragments longer than 49 and shorter than 72 residues also bind poorly in monosomes and this may be related to stable base-pairing of the extreme 5' end of the RNA which becomes possible (Fig. 5*b*) in fragments of 50 residues or longer. Alternate base-pairing schemes of theoretical stability comparable to that shown in Fig. 5*b* can be written for the first 50 bases of BMV RNA3, and transitions between these various structures may also play a part in determining the ribosome binding efficiency of different fragments. As stable base pairing is not possible in fragments shorter than 35 or so residues, though, secondary structure effects have not influenced the transition to competence for monosome formation which occurs between fragments 26 and 29 residues long.

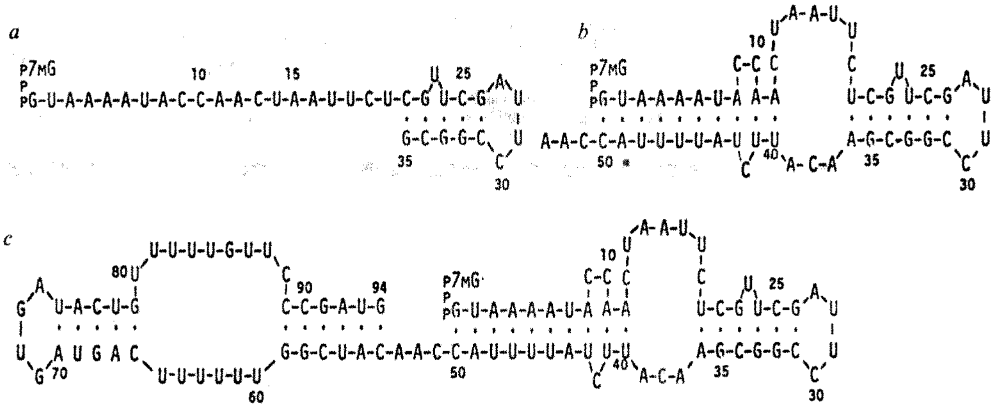

Fig. 5 Possible secondary structures for: *a*, the first 35 residues of BMV RNA3; *b*, the first 53 residues of BMV RNA3; *c*, the first 94 residues of BMV RNA3.

80S monosome formation in the absence of an AUG

Identification of the monosome peaks in Fig. 1 as complexes of mRNA with one 80S ribosome, rather than with two 40S ribosomes, is based on two observations. First, the monosome peak in each gradient coincides exactly with the peak of UV absorbance due to 80S ribosomes (Fig. 1*a*), unlike complexes of mRNA with two 40S subunits, which are believed to sediment at the 70S position[24]. Second, complexes of mRNA with single 40S subunits, which would be expected as precursors of complexes of mRNA with two 40S subunits, are completely absent (Fig. 1*d*). The report[25] that a single bound 40S subunit can protect 54 5'-terminal bases plus the cap structure of a reovirus mRNA from nuclease digestion also argues against two 40S ribosomes being able to bind the shortest RNA fragments (29 residues) recovered from the monosome peak. The monosome binding data thus make it clear that capped RNA fragments can bind wheat embryo 80S ribosomes even if they do not contain an AUG codon. 80S complex formation in the absence of an AUG codon has been described before with a capped synthetic copolymer of A and U (ref. 26), but not to our knowledge with natural mRNA 5' ends. These observations clearly conflict with the proposal of Kozak and Shatkin[27] that 60S ribosomal subunits bind to mRNA only after the 40S subunit is bound to an AUG codon. As discussed below, the possibility thus arises that initiator AUG recognition may be accomplished in normal translational initiation by the 80S ribosome rather than the 40S subunit alone.

Disome binding and two-step 80S ribosome binding

Movement of ribosomes between different sites on RNA3 is not directly tested by our experiments. However, if ribosome interaction with the site(s) 5' to the AUG has functional significance in protein synthesis it must be followed by transfer of the ribosome to the AUG site where translation commences. Disome formation with RNA3 thus indicates the existence of a ribosome entry site or alternatively a ribosome holding site. The entry site would consist of the cap plus a set of bases involved in the first stable attachment of 80S ribosomes to the RNA. The hypothetical holding site would consist of a set of bases (excluding the cap) that would accept ribosomes from an entry site and release them to a protein synthesis initiation site.

Why is there a sudden jump in efficiency of disome formation at 94 residues? Ribosome protection experiments as well as weak disome formation with fragments as short as 69 residues suggest that there is sufficient room to accomodate two ribosomes on fragments shorter than 94 residues. High efficiency disome formation therefore seems to be specifically related to recognition of the AUG codon at bases 92–94. Possibly the reason disome formation is suppressed in fragments lacking an AUG is that some feature near the 5' end of the RNA involved in binding the second ribosome remains attached to or covered by the first ribosome until the latter is stably bound at an AUG codon.

Our observations indicate that the binding of eukaryotic ribosomes to mRNA is (at least) a two step process. We suggest that eukaryotic 80S ribosomes first bind to mRNA at an entry site 5' to the initiation codon. After this binding the ribosome moves to an initiation site, recognised primarily by the presence of an initiation codon, where translation will begin. An intervening transfer to a ribosome holding site may also occur. Our observations are consistent with the possibility that 80S ribosomes move from the entry/holding site to the AUG by sliding along the mRNA, as suggested by Kozak and Shatkin for 40S ribosomal subunits[27]. Alternatively ribosomes may be brought close to the AUG by folding of the mRNA. Figure 5*c* shows a relatively weak, though stable, folding of the first 94 residues of BMV RNA3 in which the cap region and the initiation codon are adjacent to each other. After ribosome binding at the entry site, melting of the secondary structure and reorientation of the ribosome around the AUG-containing portion of the message could give a stable complex such as those revealed by nuclease protection experiments. In cases where the 5′ untranslated region of the mRNA is long enough to permit the entry and initiation sites to be physically separated, such as BMV RNA3 and TMV RNA[28], movement of the first bound 80S ribosome from the entry site to the initiation site allows a second ribosome to bind at the entry site. In other mRNAs, particularly those such as BMV RNA4 with a short 5′ untranslated region, the entry and initiation sites may overlap or coincide, allowing only a single 80S ribosome to bind when translational elongation is blocked. A fused entry and initiation site may effect a high efficiency of initiation as is the case with BMV RNA4[7], while physical separation of the entry and initiation sites might allow a more sophisticated regulation of translation.

This work was supported by grants from the US National Institiute of Allergy and Infectious Diseases and by the US Department of Agriculture. We thank Michael Janda for technical assistance, Verne Luckow for computer analysis of the RNA sequence, and Ellen Koper-Zwarthoff for technical suggestions. We are especially indebted to Bernard Moss for providing vaccinia capping enzyme and Helen Donis-Keller for RNase Phy M.

Physics Department, Leicester University, UK

SS433 has attracted much attention following the interpretation of its optical spectrum by Margon *et al.*[1] and Liebert *et al.*[2]. A possible explanation of the Doppler-shifted Balmer emission lines has been proposed by Rees and Fabian[3] and Abell and Margon[4] in terms of two opposed jets that are ejected from the central source at speeds approaching 0.25*c* and may extend for ~50 AU (~7×10^{14} cm). Previous work has shown SS433 to be variable at radio wavelengths[5], X rays[6], IR[7,8] and also in the visible[9,10]. We report here simultaneous observations at IR and visual wavelengths which show that SS433 has an IR excess. We attribute this to a region of gas that radiates by free–free and free–bound emission processes with a total emission measure of the order of 10^{61} cm^{-3}.

We observed SS433 in bands *BVJHK* on three nights during the week 14–21 May 1979, from the Cabezon Observatory, Tenerife, using the 1.5 m IR flux collector. Our observations were made using the Leicester University IR/visual photometer with a standard set of filters and an InSb detector operated at 63 K. The standard used was θ Aql, the magnitudes being taken from Johnson[11]. The reduced fluxes are shown in Table 1 together with the phases (ϕ) computed from the ephemeris of Martin *et al.*[12].

These results show three pronounced features: first, an enormous apparent excess of IR over optical flux; second, an almost flat spectrum for wavelengths >1.2 μm; third, a variation of IR and optical flux together on a time scale of several days. The first feature is certainly exaggerated by the heavy reddening of the object and may even be entirely due to it, so we have plotted in Fig. 1 corrected fluxes, assuming a value for the interstellar extinction of $A_v=6$, and a standard extinction curve[13]. The errors on each point are too small to represent on the figure. Taking $A_v=6$ corresponds to Clark and Murdin's[14] estimated colour excess of $E(B-V)=2$.

The correction for reddening leaves clear evidence for an intrinsic IR excess; for $A_v=6$ the IR points all lie above the extrapolation of the optical continuum, whose slope also agrees well with the spectrophotometry of Margon *et al.*[1], corrected for $A_v=6$.

This conclusion is further supported by Glass' (ref. 7) observation that $K-L=0.71$. With $A_v<6$ the IR continuum is even flatter. Since it is generally assumed (see ref. 1) that $A_v\geqslant5$ we shall consider $A_v=6$ as a representative case; it will be clear how the following remarks are affected by assuming other values of A_v. In particular, for large assumed values of A_v, the optical continuum is always much steeper than the IR continuum.

In interpreting these data we must explain the clear intrinsic excess at wavelengths $\gtrsim1$ μm; four possibilities are investigated here.

(1) High-frequency continuation of the radio spectrum: SS433 is a variable (~factor 3) radio source[15,16] with a nonthermal spectral index varying between −0.6 and −0.48. With the flux levels quoted in the GHz range, even the most

0028-0836/79/390282—02$01.00

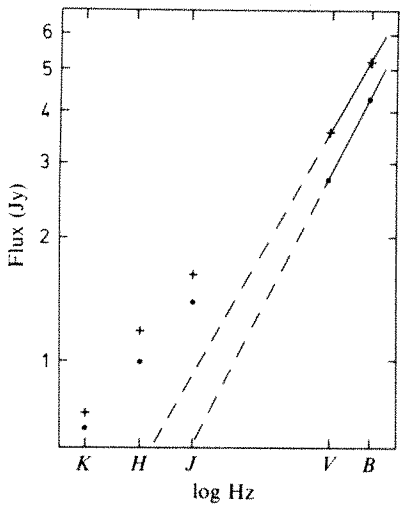

Fig. 1 Corrected fluxes from SS433 assuming that the interstellar extinction $A_v = 6$. Measurements taken on 19 (•) and 21(+) May 1979.

Table 1 Reduced fluxes observed from SS433* and phases

	May 1979 14	19	21
K	414 ± 38	420 ± 16	453 ± 13

ϕ†	0.138	0.169	0.181

* Fluxes are given in millijanskys with errors of $\pm 1\sigma$.
† Phases computed after Martin *et al.*

optimistic extrapolation gives a flux ≤ 1.5 mJy at 1 μm, as opposed to the observed ~500 mJy. Hence some way of causing the nonthermal radio spectrum to flatten above 10 GHz must be found if this hypothesis is to be sustained; this does not seem to be the simplest explanation in view of possibilities (3) and (4) below.

(2) Circumstellar dust: this can be discounted almost immediately since to cause spectral flattening near 1 μm the dust would have to radiate at black body temperatures $\gtrsim$4,250 K, at which temperatures it could not survive. Also the absence of strong forbidden line radiation[1,2] implies that the gas mixed in with any dust must be fairly dense ($\gtrsim 10^8$ cm^{-3}) and would tend to destroy the dust by sputtering.

(3) A red stellar component: a black-body continuum at a temperature near 4,250 K will account for the spectral flattening near 1 μm as noted in (2) above. If this is due to a star its spectral type must be near K. Taking $A_v = 6$ and attributing the K magnitude of the object entirely to this hypothetical star we find $M_K \simeq -5.4$ at the usually assumed distance of 3.5 kpc (ref. 1). A colour $V - K \simeq 2.7$ appropriate to a K-type star gives $M_v \simeq -2.7$ at 3.5 kpc, so a star near spectral type K3II is indicated. Since M_v for the system is less than -4.5 with $A_v = 6$ the red star's spectrum would be completely unobservable in the optical. This explanation clearly requires the system to contain at least two components; a binary hypothesis is attractive if accretion on to a compact object turns out to be the underlying 'engine' for the relativistic gas motions. The main difficulty with this explanation of the IR data is the observed variation of the IR flux; apart from the steady increase reported here, Glass[7] observed variability of 0.8 mag at 2.2 μm. A steady variation might conceivably be due to long-period binary motion, but any more complicated variability[8] would probably have to be attributed to some other component of the system. If the variability is substantial this other component must supply most of the IR flux, so that an explanation of the spectral flattening would still be lacking.

(4) Free–free and free–bound emission from an optically thin gas: the continuum spectrum of such a gas at temperatures $\sim 10^4$ K would provide a good fit to the observed IR spectrum, allowing for some 'contamination' at short wavelengths due to the intrinsically steep optical continuum (if $A_v \gtrsim 6$). Evidence favouring this hypothesis comes from the great strength of Hα; with $A_v = 6$ the reddening near Hα implies an unattenuated flux of order 10^{-9} erg s^{-1} cm^{-2} in the three observed components[1,2]. If Hα is interpreted as a recombination line, as seems reasonable, this implies that the plasma emitting it produces a free–free continuum of order 500 mJy at frequencies $\nu \ll kT/h$, where T is the electron temperature of the plasma. (The ratio of the total strength of recombination Hα to the free–free continuum at such frequencies is almost independent of temperature). In other words, if Hα is produced by recombination, the continuum emission from the gas producing it will give an IR continuum of just the observed order if $A_v \simeq 6$. (Thus hypothesis (3) above would require also that Hα be produced from a predominantly neutral gas to explain the lack of observed free–free emission, unless A_v is assumed ≤ 4) If the IR flux $\simeq$500 mJy is interpreted as free–free emission from a gas near 10^4 K an emission measure $N_e^{\,2}V$ of order 10^{61} cm^{-3} is required, with only a weak dependence on the assumed temperature, assuming a distance of 3.5 kpc. The night-to-night variability in the IR implies a typical size $R \leq 10^{15}$ cm for the emitting region; with $V \sim R^3$ we see that the average electron density $N_e > 10^8$ cm^{-3}, accounting for the absence of observed forbidden-line emission. These limits imply a free–free optical depth $\tau_{ff} \gtrsim 10^{23}\nu^{-2}$, so the continuum will be optically thick and decline as ν^2 for frequencies $\nu < 10^{11}$ Hz; hence it will be unobservable in the radio region. To ensure that the continuum is optically thin at observed IR wavelengths implies $R > 10^{12}$ cm, $N_e < 10^{12}$ cm^{-3}. The emission measure 10^{61} cm^{-3} would imply a total cooling rate of order 10^{36} erg s^{-1}, much of which (in the absence of forbidden-line cooling) should appear as UV resonance lines. This cooling rate is of the same order as the observed 2–10 keV X-ray luminosity[6] (3×10^{35} erg s^{-1} at 3.5 kpc) and thus suggests photoionisation as the energy input to the emitting gas. As this is likely to lie far out from the central object, possibly near the ends of 'jets'[3,4], it would not intercept the line of sight to the X-ray source and hence not lead to an intrinsic photoelectric turnover in the X-ray spectrum. If photoionisation is the energy supply of the gas, the variability in the IR is readily explained by the variability of the central source, as observed in X rays.

We conclude that the IR emission from SS433 is most easily explained by free–free and free–bound emission from a region of gas with $10^{12} < R < 10^{15}$ cm, $T_e \sim 10^4$ K, $10^8 < N_e < 10^{12}$ cm^{-3} and a corresponding emission measure of the order of 10^{61} cm^{-3}, although an additional stellar component cannot be ruled out. More detailed speculation clearly requires both long term IR monitoring and some simultaneous IR–optical–X-ray observations.

Infrared observations of SS433

David A. Allen

Anglo-Australian Observatory, P.O. Box 296, Epping,
N.S.W. 2121, Australia

The special features of SS433 have been chronicled over the past 12 months[1–4]. Most unusual of its features is the triple set of hydrogen and helium emission lines. Whilst one of these sets remains at rest, the other two exhibit velocity peregrinations of amplitude 0.27 *c*. These moving satellites have been interpreted[5,6] as outflowing gas in directly opposing jets which precess with a period of 164 days. I describe here observations of SS433 in the 1–4-μm spectral region made in March and April 1979 with the 3.9-m Anglo-Australian Telescope. These observations show that the Paschen and Brackett lines of hydrogen also exhibit moving satellites, substantiate the high reddening deduced from optical data, and indicate surprisingly strong free–free emission in the near IR.

All observations were made in daylight using the newly constructed IR photometer–spectrometer. Spectra covering the 2.0–2.5-μm region at a resolution ($\lambda/\Delta\lambda$) of 50 were taken on seven occasions from March 9 to April 15. All show emission features due to hydrogen. Within this spectral region only Bγ appears at zero redshift, at a wavelength of 2.17 μm. The moving satellite lines of Pα, Bβ and Bδ have also been identified, with the help of the ephemeris of Abell and Margon[5]. Table 1 lists numerical data on the spectra. Three of the spectra are shown in Fig. 1, and the motion of the satellite lines is evident from a comparison of the March 11 and April 6 data. In addition, the prominence of the satellite lines varies on a daily time scale, as can be seen from the March 9 and 11 data, and Table 1. Similar intensity fluctuations of the satellite lines are evident in much of the data (mostly unpublished) of various observers using the Anglo-Australian Telescope.

It would be of interest to compare the intensities of Bγ and the Balmer lines, and hence to derive a direct estimate of the reddening. So far, this comparison has not been possible due to the lack of concurrent optical data. The relative intensities of the rest and moving features appear to be much the same at visible and IR wavelengths, suggesting that all three gaseous regions experience similar reddening. The equivalent width of the Bγ line, which can be observed uncontaminated by satellite lines only when the latter are absent, on two of the seven spectra is 170 ± 30 Å; this figure may be overestimated by the inclusion of the strongest of the satellite lines (Pα) on the second occasion.

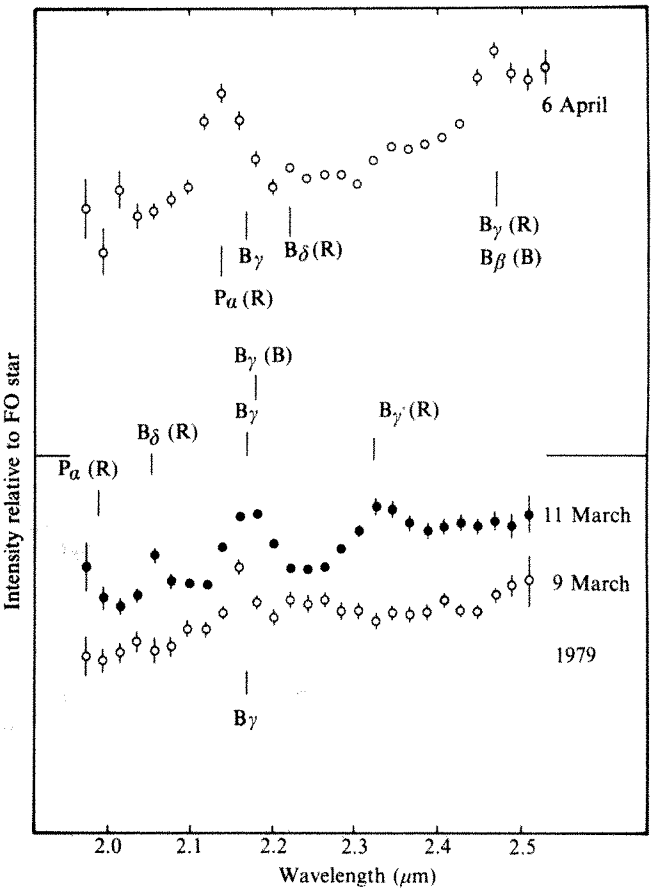

Fig. 1 SS433 2-μm spectra on three dates in 1979. Each spectrum was divided by that of the FO star ξ Ser to remove the telluric features, and all are reproduced at the same scale. The emission lines marked are the rest wavelength of Brackett γ, and the expected positions of the moving satellites. The latter are coded R and B according to whether the optical equivalents normally appear to the red or blue of rest.

Table 1 Observed emission lines in SS433 and their identifications

UT date 1979	Observed wavelength (μm)	Identification	Predicted wavelength (μm)	Equivalent width (Å)

		Pα(R)	2.18	
	2.39	Bβ(B)	2.39	100

Photometric observations were possible on only five occasions, due to the presence of cirrus at other times, and only on March 9 were data taken at all four available wavelengths of 1.25 (J), 1.65 (H), 2.2 (K) and 3.8 μm (L'). Over the month of observation the star monotonically brightened by half a magnitude at J, H and K. Of this increase, 0.3 mag occurred between 9 and 11 March (Fig. 1). The IR brightening has since halted according to the 1979 May data of Glass[7], and an abrupt fading by 0.2 mag between 14 and 15 April was reported by Milone[8].

It is necessary to correct the measured broad-band data for the influence of the emission lines. On 9 March the satellite lines were weak, and a reasonably accurate correction can be determined. Bγ contributes about 0.03 mag to the K datum. Using a reddening estimate of $A_V \sim 5$ (see below) and case B hydrogen line recombination ratios[9,10] for temperatures of the order of 10^4 K, the other corrections were estimated as follows: to J 0.03 mag due to Pβ at 1.28 μm, to L' 0.04 mag due to Bα at 4.05 μm. The corrected continuum magnitudes are: $J = 9.76 \pm 0.04$; $H = 9.10 \pm 0.02$; $K = 8.45 \pm 0.02$; $L' = 7.63 \pm 0.05$.

Two distinct estimates of the reddening experienced by SS433 have been attempted. One makes assumptions about the underlying star, which although plausible are not conclusive for such a controversial object. The other relies on a proved correlation between the reddening and the depths of certain unidentified absorption bands in the visible spectra of reddened stars. These estimates agree on a value for $A_V \sim 6$–7 (refs 1, 3). A third estimate can be derived from the IR photometry. This also makes assumptions about the underlying star, but the assumptions are perhaps more plausible than those pertaining to the optical region alone. In addition, the very presence of $B\gamma$ when $H\varepsilon$, which shares the same upper level, is too faint to have been observed indicates substantial reddening.

No mechanism is known at near IR wavelengths that produces a spectrum steeper than the Rayleight–Jeans tail of a black body. For the observed J–H colour, this imposes an upper limit of $A_V \leq 8$. Correction for $A_V = 8$ does not give a match to a Rayleigh–Jeans tail, in the sense that there is excess radiation at longer wavelengths. This we should in any case expect, due to free–free emission from the gas which produces the emission lines. A satisfactory fit can be achieved by a combination of a hot star and free–free emission for $4 \leq A_V \leq 6$. This also reproduces the observed (variable) visual magnitude of 13–14 (refs 3, 11) for K in the observed range 8.0–8.5. For $A_V = 5 \pm 1$, the contribution of the free–free component near $B\gamma$ can be estimated as 60±10%, and thus the equivalent width of $B\gamma$ on March 9 in terms of the free–free continuum is about 210±40 Å.

For gas temperatures in the range 5,000–20,000 K the expected equivalent width of $B\gamma$ relative to the free–free continuum[10,12] ranges from 900 to 400 Å. A value in this range was measured by the same equipment in the planetary nebula NGC 2440. An equivalent width of 210 Å implies an excessively high temperature; a better hypothesis is that an additional free–free continuum is present. One source of such a continuum is the gas producing the satellite lines. However, as the only measurements of the $B\gamma$ equivalent width were made when the satellite lines were weak, any free–free emission from the gas producing them would also be expected to be weak. Another possibility is that an abnormally high abundance of elements heavier than helium is present in one or all of the gaseous systems. The possible association of SS433 with a supernova remnant[1,2] lends some credence to this suggestion. Finally, a very small amount of dust radiating at a colour temperature of 1,000–1,500 K could provide the extra continuum required.

I thank Martin Ward, Alan Wright and Malcolm Smith for help with the observations and comments, and Bruce Margon for data before publication.

H2155 − 304: a highly luminous BL Lac object

Philip Charles, John Thorstensen & Stuart Bowyer

Space Sciences Laboratory, University of California, Berkeley, California 94720

The radio source PKS2155 − 304 has recently been identified[1] with a HEAO 1 X-ray source and a ~14 mag object that has a featureless spectrum and is interpreted as a member of the BL Lac class. We describe here our optical spectroscopy of this object which reveals two weak emission features at λ5,820 and 5,870 Å. We suggest that these lines are [O III] λ4,959, 5,007 redshifted by $z = 0.17$. This result supports the interpretation of H2155 − 304 as a highly luminous BL Lac object.

The discovery of an intense soft X-ray source, H2155 − 304, at high galactic latitude[2] using the HEAO 1 A-2 experiment was followed by an accurate location with the A-3 modulation collimator[3]. This enabled a ~14 mag object to be proposed as the optical counterpart[1] which is within 1 arc s of the flat spectrum, point radio source PKS2155 − 304 (refs 4, 5). Optical spectroscopy of the candidate star[1,6,7] has shown that: (1) it is blue, $B - V < 0.1$; (2) it has a featureless spectrum, with upper limits to emission lines of 2–4 Å (ref. 7) and ~1 Å (ref. 1); and (3) it is variable in magnitude and colour on a time scale of months. Polarisation measurements[1] also showed a significant (~5%) wavelength dependent polarisation which decreased over ~3 months while the object brightened. The object was also found to be associated with a faint, asymmetric nebulosity[1]. This evidence is all highly suggestive of an elliptical galaxy whose nucleus contains a BL Lac object. Spectral features in BL Lac objects are extremely weak (if detectable at all)[8] as is evidenced by the difficulty in observing the emission lines from

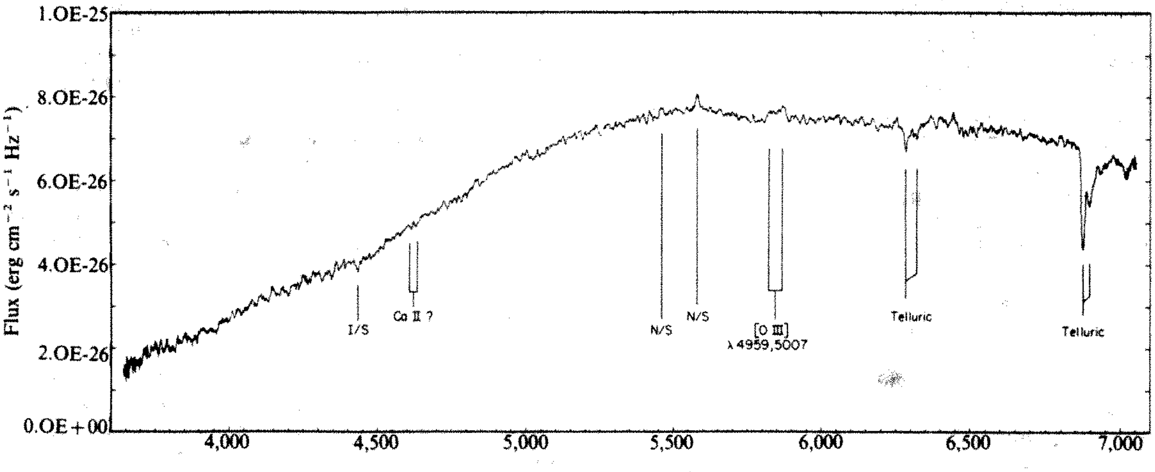

Fig. 1 Lick 3-m ITS spectrum of H2155 − 304 summed from three nights of observations in October 1978. The marked feature at ~λ 5,850 is identified with [O III] λ 4,959, 5,007 redshifted by $z = 0.17$. Features marked N/S are due to improperly subtracted night sky lines; the broad absorption bands are due to atmospheric O_2.

the nucleus of BL Lac itself[9] and the surrounding galaxy[10]. The optical spectroscopy of H2155 − 304 reported so far has either been of very poor spectral resolution (~40 Å)[7] or of limited sensitivity due to short observation time[1,6]. We therefore decided to undertake a series of observations of this object with the Lick Observatory 3-m Shane reflector and image tube scanner (ITS)[11] to acquire spectrophotometric data of high sensitivity. Our observations were made during the period 24–27 October 1978 and were reduced to an absolute flux level[12] by comparison with observations of standard stars[13]. Several integrations taken in good seeing conditions through relatively large (4 × 4 arc s) observing apertures, and guided so as to minimise the effects of atmospheric dispersion, yielded a mean V of 14.2 ± 0.1 and $B - V = 0.5 \pm 0.2$, substantially redder and fainter than the object appeared 6 weeks later[1]. The total mean spectrum of H2155 − 304 is shown in Fig. 1.

Of principal interest in this spectrum is the somewhat broad, double-peaked emission feature centred on λ5,850. Night sky features (due to imprecise sky subtraction) are marked N/S. If we interpret the emission feature as arising from two lines at λ5,820 and 5,870 we derive equivalent widths of 0.54 and 0.96 Å, weak, but certainly significant at this signal-to-noise ratio. Additional support for the reality of these lines comes from: (1) there are no night sky lines that, if improperly subtracted, could give rise to such a feature; (2) the lines are present on all three nights that this object was observed although at a reduced level of significance so that the feature is only statistically significant in the summed spectrum; (3) irregularities in the image tube would be extremely unlikely to produce such a feature because we adjusted the grating setting so as to cover a different wavelength range each night; thereby any real feature would move along the tube (as observed) whereas a tube 'hot spot' would not.

Comparison with the BL Lac spectrum[9] immediately suggests the identification of the H2155 − 304 lines with [O III] λ4,959 and 5,007. The implied redshift is $z = 0.17$ and hence $L_{\text{opt}} = 7.5 \times 10^{45}$ erg s^{-1}. At this redshift we have marked in Fig. 1 the implied position of Ca II H and K which might be present weakly in absorption (although there are other stronger features than this which are unidentified). Typically, these lines are easily resolved in active galactic nuclei with this instrument; in our spectrum, they are only marginally separated. An alternative identification for our feature, which circumvents this difficulty, is Doppler-broadened Hβ emission. However, the higher Balmer lines are not observed, rendering this hypothesis less attractive, unless the Balmer decrement is quite steep.

At this redshift H2155 − 304 is ~50 times brighter than BL Lac itself and in Table 1 the optical, radio and X-ray properties of the four definitely-identified X-ray emitting BL Lac objects are compared with H2155 − 304. The ~10 arc s nebulosity associated with H2155 − 304 has a physical diameter ~50 kpc at the Hubble distance of 1,020 Mpc (assuming $H_0 = 50$ km s^{-1} Mpc^{-1}) which, it has been pointed out[1], is not inconsistent with a large ellipitical galaxy. It would therefore be extremely valuable to use the technique of Miller *et al.*[10] to search for absorption lines in the galaxy spectrum and thereby (1) verify the redshift and BL Lac designation, and (2) investigate the stellar contribution to the nebulosity and compare it with those around QSOs. Given the variability of this object, its continued study spectroscopically is of considerable importance in the search for other lines and variability in the [O III] feature.

This work has been supported by the NSF under grant AST 78-06873. Stuart Bowyer acknowledges the support of a Miller Professorship. We thank Richard Griffiths and Santiago Tapia for useful discussions and for results before publication.

A relationship between the amplitude of the susceptibility and the frequency of the maximum dielectric loss

R. M. Hill & L. A. Dissado

Department of Physics, Chelsea College, University of London,
Pulton Place, London SW6, UK

We recently presented a new theory of dielectric behaviour based on a many-body cooperative model of interacting dipoles[1]. It was shown that the experimentally observed non-Debye behaviour of many dielectric materials[2] can be represented by these interactions, and a relationship for the frequency dependence of the susceptibility which describes the observed behaviour was presented. The temperature dependence of the simplest dielectric materials which exhibit a dipole alignment transition has now been examined in detail[3]. One consequence of the cooperative theory is particularly novel and is reported here.

In a conventional dielectric the amplitude of the susceptibility is taken as proportional to the inverse temperature, or as proportional to the inverse of the difference between the temperature and the Curie temperature in a ferroelectric material. The frequency at which the loss peak occurs is simply activated, with the activation energy representing the potential difference between the meta-stable dipole potential minima and the maximum in the barrier between them[4]. It is known, however, that in the region of a phase transition, or the Curie temperature, that the frequency of the loss peak tends asymptotically to zero at the critical temperature[5]. The many-body

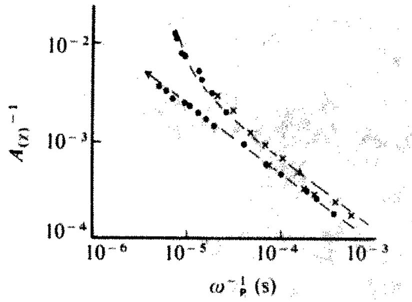

Fig. 1 A plot of the inverse of the amplitude of the susceptibility against the inverse of the frequency of maximum loss for $AgNa(NO_2)_2$ from the measurements of Gesi. Data from ref. 7 (○) and ref. 8 (×). The gradient of the parallel lines is −0.71.

theory[1,3] gives both of these features as a direct consequence of the basic assumptions. Furthermore the model predicts a set of intrinsic relationships between the magnitude of the susceptibility, $A_{(x)}$, and the peak frequency, ω_p. We have reinterpreted published data to show that one of these conditions has in fact been observed experimentally.

From equation (17) of ref. 1 the frequency at which the peak in the dielectric loss occurs is given by

$$\omega_p = \nu_e \cosh\left(\frac{B + kT_cM_e}{kT}\right)\{1-(1-M_e^2)\mathrm{T}_c/T\} \qquad (1)$$

The significance of the symbolism is given in that reference. From equations (27) and (31) of ref. 1 the magnitude of the susceptibility is proportional to

$$\omega_p^n \cos\left(\frac{n\pi}{2}\right)\zeta^{-n}M'_{(0)} \times F(\omega/\omega_p)$$

where $F(\omega/\omega_p)$ is the shape function normalised to ω_p. On substituting for the zero time value of the mean magnitude of the z component of the local unit dipole vector perturbation, $M'_{(0)}$, this expression can be written in the form

$$A_{(x)} = \left(\frac{\omega_p}{\zeta}\right)^n \cos\left(\frac{n\pi}{2}\right)\frac{(1-M_e)^2}{kT}\{1-(1-M_e^2)T_c/T\}^{-1} \qquad (2)$$

In the region of the critical temperature, T_c, the terms in parentheses in equations (1) and (2) dominate both the peak frequency and the amplitude of the susceptibility. Under this condition it follows that

$$A_{(x)} \propto \omega_p^{-(1-n)} \qquad (3)$$

Alternatively if the temperature T is not close to T_c the activated term in equation (1), ν_e, dominates and

$$A_{(x)} \propto \omega_p^n \qquad (4)$$

These relationships show the generality of the parameter n (ref. 6), which has been shown to be the measure of the degree of correlation of individual tunnelling dipolar transitions in the medium[1].

The properties of $AgNa(NO_2)_2$, which is a ferroelectric crystal with a low transition temperature (37.8 °C) have been reported by Gesi[7,8]. A compilation of these measurements is shown in Fig. 1, in which the inverse of the susceptibility amplitude has been plotted against the inverse of the peak frequency. The inverse functions have been used as the tracing technique for susceptibility normalisation described in ref. 2 results in temperature shift points which are these inverse functions. Figure 2 shows two parallel lines, one for temperature less than the critical value and the other for temperatures above T_c. The lowest temperatures investigated show a deviation away from the linearity condition towards the region of positive gradient contained in equation (4). The gradients of the lines are $-0.71 = -(1-n)$ and comparable to the equivalent value of $-(1-n)$ measured from the high frequency region of the normalised susceptibility/frequency plot for this material of 0.68. Similar results have been observed from Nakamura and Hosoya's measurements[9] on $Ca_2Sr(C_2H_5CO_2)_6$. In this case the magnitude of $(1-n)$ was 0.99.

We know of no alternative explanation for this specific interrelationship between the amplitude and the frequency of the maximum in the dielectric loss. Hence Fig. 1 presents direct experimental evidence for the validity of the many-body, cooperative, model proposed earlier.

We acknowledge the SRC assistantship held by L.A.D.

Stable ridges in a collapsing monolayer

Herman E. Ries Jr

Department of Biology, The University of Chicago, Chicago, Illinois 60637

The nature of monolayer collapse has long interested physical chemists studying surface phenomena[1–3], and is also of interest to biologists seeking cell-membrane models[4], since monolayers of fatty-acid type molecules are often used as models for each half of the biomembrane bilayers, and double layers or bilayers may well form on monolayer collapse. Furthermore thin-film properties of fatty acids are similar in many ways to those of cholesterol, lecithins, and other important components of biomembranes. There is little direct experimental evidence to support proposed collapse mechanisms, however. In this note a remarkable type of monolayer collapse is described. Pressure–area isotherms for 2-hydroxytetracosanoic (cerebronic) acid rise steeply and bend over sharply at a high pressure without the subsequent falloff in pressure expected for such rigid films. Electron micrographs of the collapsing film clearly show many folds or ridges of unusual stability. The compressed monolayer thus provides a model for membranes and thicker films under compression.

2-Hydroxytetracosanoic acid, obtained in high purity from Supelco Inc., was spread from a dilute benzene solution onto distilled water of pH 7.0. Pressure–area measurements were made using the Langmuir–Adam–Harkins technique[1,5]. Film samples were transferred to Formvar-coated electron microscope grids by a modified Langmuir-Blodgett method[6]. Transferred films were shadowcast in the direction of compression with platinum–palladium at an angle of 10° before examination in a Siemens Elmiskop 101 (ref. 7).

The data for duplicate determinations of the pressure–area isotherm are plotted in Fig. 1 and demonstrate the high reproducibility of the measurements. Extrapolation of the linear portion of the isotherm gives a cross-sectional area of 26 Å^2 per molecule. Monolayer compressibility is 0.0047 cm dyn^{-1} and the collapse pressure (without falloff) is 68 dyn cm^{-1}. Lycopodium tests demonstrate the extreme rigidity of the film. Compression-expansion-recompression experiments in the low-pressure region show negligible hysteresis. Water insolubility and surface mobility are thus established. [If any appreciable quantity of benzene is retained in the surface in our conditions it has little effect on the significant part of the pressure-area isotherm (the upper linear portion). These upper linear portions virtually coincide for benzene, hexane, and no

0028-0836/79/390287—03$01.00

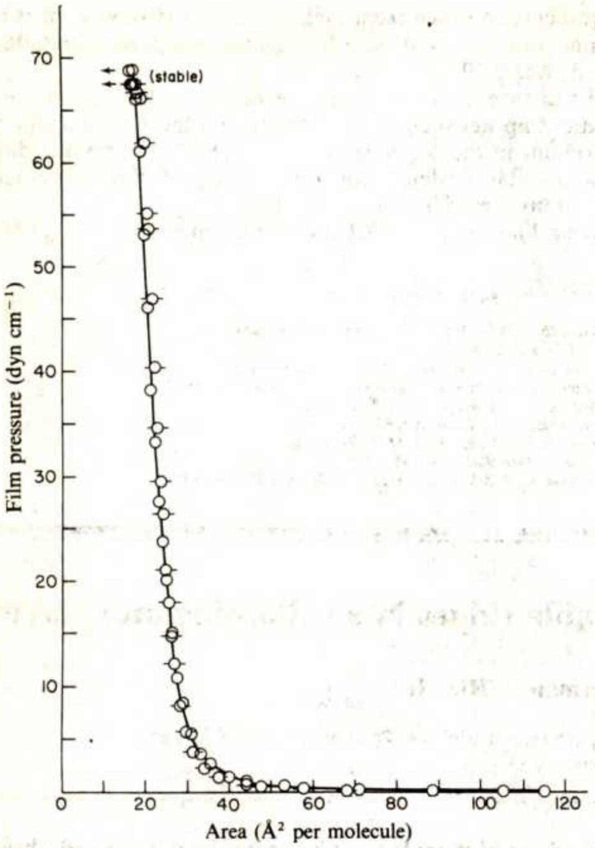

Fig. 1 Pressure-area isotherms for 1-hydroxytetracosanoic acid at 22 °C

solvent[8,9]. In contrast ethanol has a major effect on the isotherm[10].]

Essentially all rigid or solid-like films have previously shown a precipitous fall in pressure at the collapse or maximum pressure. A probable explanation is that such films break up into double-layer fragments as shown schematically in Fig. 2. Earlier electron micrographs of transferred films have supported this mechanism in which long narrow double-layer platelets form in four successive steps: weakening, folding, bending and breaking[3,11].

In Fig. 3, micrographs of the collapsing film of 2-hydroxytetracosanoic acid show essentially no broken fragments. Most striking is the high concentration of tall ridges or folds and the absence of fallen ridges or flat platelets. The ridges are oriented normal to the direction of compression. Many are approximately 2,000 Å in height or the equivalent of about 400 horizontally oriented molecules. In previous studies of solid-type films, such as those of fatty acids and cholesterol, only a few relatively isolated ridges were observed before the appearance of broken double-layer platelets[3,5,11]. The breaking off of these platelets from the monolayer proper probably accounts for the precipitous fall in pressure usually observed. Without the breaking off of the ridges in the case of 2-hydroxytetracosanoic acid, the monolayer continues to exert its maximum pressure.

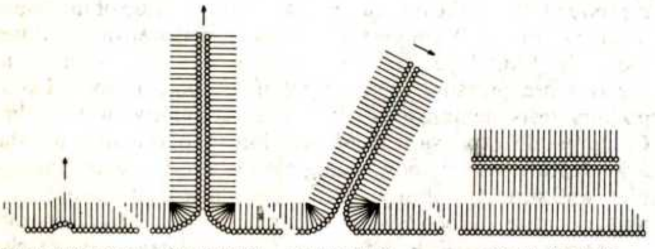

Fig. 2 Mechanism of monolayer collapse.

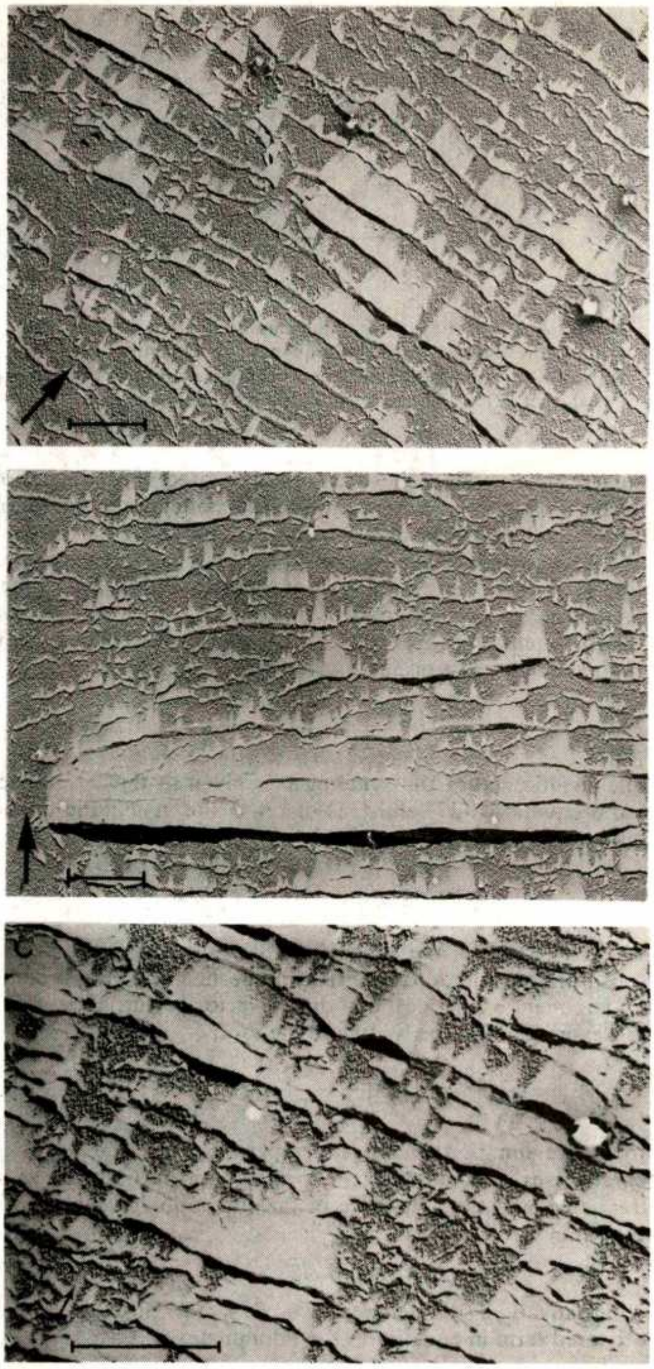

Fig. 3 Electron micrographs of collapsing films of 2-hydroxytetracosanoic acid. Arrows indicate the direction of shadowcasting and shadows appear as light areas. Scale bars, 1 μm.

Evidently the ridges have great stability in that they withstand the mechanical and thermal shocks of transfer, degassing and shadowcasting. Stability of the ridges and the remaining monolayer may well be provided by the cohesion of the 24-carbon atom chains combined with the intermolecular adhesion (H-bonding) of the hydroxy and carboxy groups. Furthermore, the ridges may provide a reservoir to replenish molecules lost from the monolayer. Collapsed or broken-off platelets would not provide a readily available reservoir because the polar groups of their component molecules could not easily contact the water surface.

Both the concentration and orientation of the ridges provide strong evidence that the compressed monolayer behaves much as a thicker sheet. The monolayer of 2-hydroxytetracosanoic acid may thus serve as an important model for cell membranes and other thicker film systems.

I thank Professor Hewson Swift for his advice and suggestions and Dr Christopher Chou and Mr Walter E. Ries for technical assistance.

Total gas content and surface elevation of polar ice sheets

D. Raynaud & B. Lebel

Laboratoire de Glaciologie du CNRS, 2, rue Très-Cloîtres,
38031 Grenoble-Cedex, France

Interpretation of stable isotope profiles from polar ice cores in terms of past climate requires a knowledge of the elevation at which the ice found at any depth was formed. Measurement of the total gas content of polar ice, *V*, can give such information if the volume of the pores in ice is known for the time they close off from the atmosphere at the ice formation site[1]. For the 1,387-m long core from Camp Century in north-west Greenland, estimates, based on the assumption of a constant pore volume at close-off, suggested that, on the average, ice from the Wisconsin/Weichsel period was formed at an elevation about 1,200–1,400 m higher than that from the Holocene[2]. This would account for an important part of the large shift in the stable oxygen isotopic ratio in this core between late Wisconsin and Holocene ice that was observed by Dansgaard and others[3]. However, if the pore volume at close-off depends on the site of origin for the ice, estimates of elevation of origin by the gas content method can be seriously in error unless the effect can be allowed for quantitatively. We present here results that enable us to describe the variations in the total gas content of ice that has been formed in present-day conditions in Antarctica and Greenland for a wide range of temperature (−12 to −53 °C) and elevation (400 to 3,200 m). Using these results, the gas content method can now be applied with much greater confidence than before to indicate past elevation changes.

The total amount of gas measured in ice formed by dry sintering of snow can be expressed as:

$$V = V_c \frac{P_c}{T_c} \frac{T}{P} \tag{1}$$

in which V is reduced to standard temperature T(K), standard pressure P, and 1 g of ice; V_c (per gramme of ice) is the pore volume when the pores are finally closed off in the firn at temperature T_c(K) and air pressure P_c. The conditions required for applying equation (1) are discussed in ref. 4. P_c and T_c depend mainly on the atmospheric pressure and temperature prevailing at the snow surface and, in the case of recently formed ice, they can be estimated from meteorological surface observations and temperature measurements in the drilled holes.

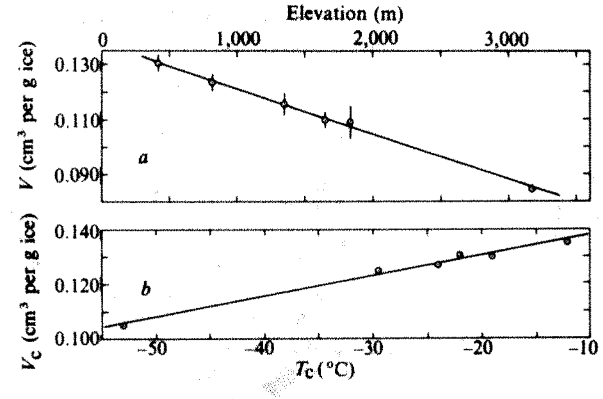

Fig. 1 Total gas content of Antarctic and Greenland ice versus the elevation of formation site *a*, and derived pore volume at close-off versus temperature at the formation site *b*. Standard deviations of the measured mean *V* values are indicated in *a*.

In order to analyse how the total gas content depends on present-day conditions, we have performed 142 determinations of V on ice recently formed in Antarctica and Greenland and recovered by drilling at six different locations (Table 1). The gas was extracted by melting the ice and refreezing the meltwater under vacuum, then dried and collected in a volumetric gas burette using a Toepler pump. Each measurement of V was performed on 20–25 g of ice, representing a thickness of 2.5–3.5 cm in the glacier. The relative precision of the measurements has been analysed from repetitive determinations of V on natural ice sampled from the same 2.5–3.5 cm thick layers. About 50 sets of such repetitive measurements were performed. The difference between these comparable measurements in V never exceeds 2% and is on the average 0.7%.

There are systematic differences, however, between results obtained using different procedures for extracting the gas under vacuum. For two locations, Camp Century and New Byrd, the current procedure yields mean V values (see Table 1) systematically 0.006 cm^3 per g of ice smaller than those previously reported by Raynaud[4]. This does not affect gas content changes in ice deduced from the results of a single procedure, and gas content changes obtained by different procedures may be compared.

Samples have been selected among the pieces of core available to obtain the best value for the amount of gas trapped when firn turns into ice under present-day and dry conditions. In particular, core measurements have been taken from unfractured sections that are apparently undisturbed by percolating meltwater and well below the pore close-off zone (since near this zone the pore seals may be delicate and consequently changes in the original gas content can occur between core recovery and measurement). At each drilling location, ice flow modelling results and isotopic profiles of the ice indicate that the layers investigated here were formed during the Holocene, when climatic conditions were similar to today and at approximately the same site. (At Dome Summit, Camp Century, and Dome C the investigated layers were most probably formed near the drilling site; but in the case of Cape Folger, D 10, and New Byrd the origin of the ice is considered to be different from the drilling location due to glacier flow and, in the case of New Byrd, to changes in ice thickness.)

The number of determinations of V performed for each site was between 5 and 58. Corresponding mean values with standard deviations are shown in Table 1. The variations observed for a given site are generally larger than experimental errors and are, in part, due to short-term natural fluctuations. The mean values of V show a significant and mostly proportional decrease

0028–0836/79/390289—03$01.00

with respect to the elevation (E) of the ice formation site (Fig. 1*a*). The least-squares linear regression is:

$$V(\text{cm}^3 \text{ per g of ice}) = -1.66 \times 10^{-5}\, E(m) + 0.138 \qquad (2)$$

with a correlation coefficient of −0.998 which is significant at a <1% level (Student's *t*-test).

Calculation of V_c using equation (1), the mean V values, and estimated values for P_c and T_c (Table 1), indicates that about half of the observed decrease in V with respect to E is linked to the change of the ratio P_c/T_c with elevation and that the remainder is due to variations in V_c. Any systematic change in the porosity at close-off must depend primarily on firnification parameters, such as the accumulation rate and the temperature which, in particular, influences the grain size. Our results indicate no significant correlation between accumulation rate and V_c. On the other hand, a very consistent dependence of V_c on T_c is obtained (Fig. 1*b*) which can be expressed by a linear regression:

$$V_c\,(\text{cm}^3 \text{ per g of ice}) = 7.4 \times 10^{-4}\, T_c(\text{K}) - 0.057 \qquad (3)$$

the level of significance of the correlation (coefficient = 0.992) being <1% (Student's *t*-test).

A further indication of a correlation between V_c and temperature arises from the short-term variations of V recorded by the two continuous sets of increments analysed from the D 10 and Dome Summit cores (Fig. 2). The amplitudes of these variations cannot be due only to experimental errors and fluctuations in P_c and T_c. They probably reflect natural fluctuations in V_c which contribute in a significant way to the observed V variations. The comparison between changes in V and isotopic composition (δD) in Fig. 2 suggests that ice formed from snow deposited in warmer conditions (high δ values) contains a higher pore volume (high V values) than ice formed from snow deposited in colder conditions (low δ).

The results shown in Fig. 1 lead to the following relation between V, P_c and T_c (obtained from equations (1) and (3)):

$$V\,(\text{cm}^3 \text{ per g of ice}) = \left[7.4 \times 10^{-4}\, P_c - 0.057\, \frac{P_c}{T_c(\text{K})}\right] \frac{T(\text{K})}{P} \qquad (4)$$

Thus the total amount of gas trapped in polar glaciers, when dry firn turns into ice, depends on the atmospheric pressure and temperature prevailing at the formation site. In present-day surface conditions, an elevation increase of 1,000 m corresponds to a decrease in V of about 0.017 cm^3 per g of ice. This gradient is close to those obtained over much smaller elevation ranges by Budd and Morgan[7] for the Law Dome (Antarctica) and from mean total gas content values reported by Miller[8] for stations Milcent and Crête (Greenland). According to equation (4), a general climatic cooling of 5 °C at the ice formation site would imply a decrease in V of approximately 0.001 cm^3 per g of ice. These figures clearly show the potentiality of V as elevation indicator and confirm that the mean difference of

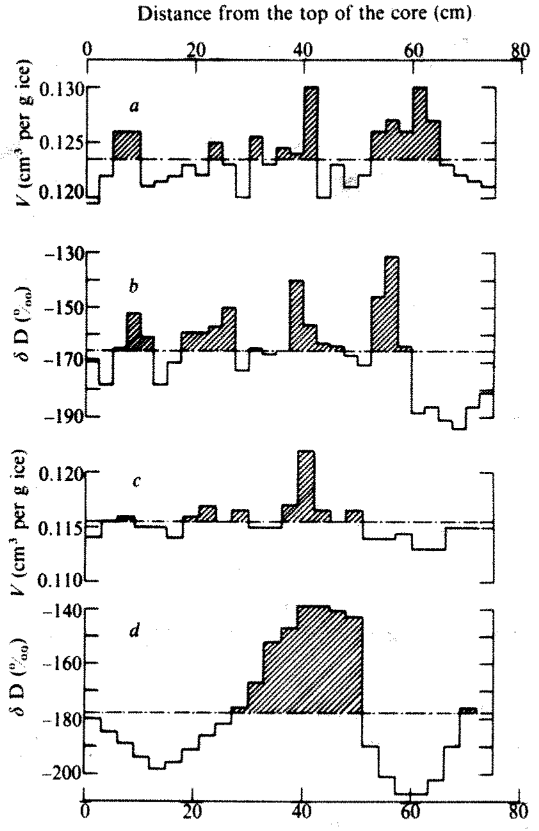

Fig. 2 Total gas and deuterium content variations observed on the two continuous sets of core increments taken at D 10 (depth range: 117.1–117.9 m below the surface), *a* and *b*, and at Dome Summit (232.0–232.7 m below the surface), *c* and *d*. The dashed lines are the average values.

Table 1 Mean total gas content, $\bar{V}$ measured on ice recently formed in Antarctica and Greenland

Drilling site	Depth interval (m below surface)	No. of determinations	$\bar{V} \pm \sigma$ (cm^3 per g of ice)	Elevation* (m)	P_c* (mbar)	T_c* (°C)	V_c (cm^3 per g of ice)
Cape Folger, F station (Law Dome, East Antarctica)	131.0–131.2	5	0.1305 ± 0.0025	420	935	−12	0.135
D10 (Terre Adélie, East Antarctica)	117.1–117.9	57	0.1235 ± 0.0030	820	895	−19	0.130
Dome Summit (Law Dome, East Antarctica)	100–233	58	0.1155 ± 0.0030	1,350	825	−22	0.1305
New Byrd (West Antarctica)	100–900	9	0.110 ± 0.003	1,650	795	−29.5	0.125
Camp Century (Northwest Greenland)	200–800	7	0.109 ± 0.006	1,840	795	−24	0.127
Dome C (East Antarctica)	155.0–155.2	6	0.0845 ± 0.0010	3,170	655	−53	0.105

The depth interval at which the ice has been taken as well as estimated elevation, atmospheric pressure (P_c) and temperature (T_c) of the ice formation location are also given for each site. V_c values are the calculated pore volumes at close-off from equation (1).

* From refs 4 and 5, except for New Byrd. For that site, according to ref. 6, the surface elevation at the origin site for the ice found now between 100 and 900 m depth is, on the average, about 150 m higher than the surface of the drill site, and P_c and T_c have been estimated taking into account a pressure–elevation gradient of 0.1 mbar m^{-1} and a temperature–elevation gradient of 0.01 °C m^{-1} for the Byrd Station area.

about 0.015 cm^3 of gas per g of ice measured between Holocene and Wisconsin ice in the Camp Century core[1] can be primarily attributed to an elevation effect. Taking into account the present-day V-elevation gradient (from equation (2)), the Wisconsin section of the core is found to be formed, on the average, at an elevation about 900 m higher than the Holocene section (which may be compared with the earlier estimate of about 1,200 m (ref. 2) which was based, among other things, on the assumption of constant V_c). The colder climate during the Wisconsin (compared with the Holocene) leads to a calculated elevation effect somewhat less; thus, if the climatic temperature change is 10 °C, the elevation difference would be about 800 m. Considering the present-day rate of decrease in stable isotope composition of ice with elevation of 0.62 δ^{18}O‰ per 100 m for Greenland[9], our new elevation estimate would account for about 5 δ^{18}O‰ or almost half of the mean isotopic difference between the Wisconsin and Holocene ice at Camp Century.

The gas content method, if extended to a wide range of polar ice cores, can provide unique information on ice origin and past thickness changes of polar ice sheets and thus enables more reliable interpretation of past climatic changes deduced from isotopic measurements on ice cores.

Denitrification in the nitrogen budget of a river ecosystem

A. R. Hill

Department of Geography, York University, Toronto, Ontario, Canada M3J 1P3

Recent studies indicate that bacterial denitrification in anaerobic sediments may play a major part in removing nitrogen from water during river transport[1,2]. As this reaction reduces nitrate-N primarily to gaseous nitrogen, it represents a potentially significant pathway for the permanent removal of nitrogen from aquatic environments. However, no detailed assessments have been made of the quantitative importance of denitrification in relation to river nitrogen budgets. I have investigated this problem by studying the role of denitrification in relation to the nitrogen budget of Duffin Creek near Toronto, Ontario, and report here that the removal of nitrate-N by denitrification in the downstream reaches of the river represents 5–6% of the annual export of total nitrogen from this river basin.

Duffin Creek has an average flow of 2.2×10^5 m^3 d^{-1} and drains a predominantly rural watershed of 262 km^2. Nitrogen transport was measured at intervals along the two main branches of the river. River discharge measurements were available from recording gauges at sites 1, 2, 3, 6, 8, 11 and 13 (Fig. 1). At the remaining sites current meter measurements coupled with cross-sectional areas were used to calculate discharges at times of river water sampling. Nitrate-N was measured in water samples colorimetrically using an automated cadium reduction method[3]. Detailed measurements of all nitrogen forms were also available for sample sites used from government water quality monitoring studies[4].

During May to October in 1973 to 1975 and in 1978 river discharge and concentrations of nitrate-N were measured on 18 days of low flow discharges. A comparison of river discharges for each channel reach indicated that inputs and outputs of water differed by less than 15% for almost all the observations. The six river reaches examined showed a consistent pattern of daily losses of nitrate-N. The mean daily loss for the 18 days varied between 1.7 kg (40 mg m^{-2} of stream bed) and 20.3 kg (300 mg m^{-2} of stream bed) nitrate-N (Fig. 1). The concentration of ammonium-N and nitrite-N was negligible during low flow conditions. Calculations of organic-N transport revealed no evidence of significant gains or losses.

Uptake of nitrogen by benthic algae and macrophytes seems to account for ~15% of the nitrates removed from the river water (A.R.H., in preparation). The possibility that nitrate losses in Duffin Creek are caused mainly by denitrification in river sediments was investigated in a laboratory experiment. Sediment samples were covered with a solution containing 5 mg per l NO_3-N as KNO_3. Water samples were removed at various time intervals and analysed for nitrate-N. The results indicated a rapid disappearance of nitrate with almost total loss occurring in some samples within 6 days (Fig. 2). Average rates of nitrate-N loss over a 6-day period ranged between 100 and

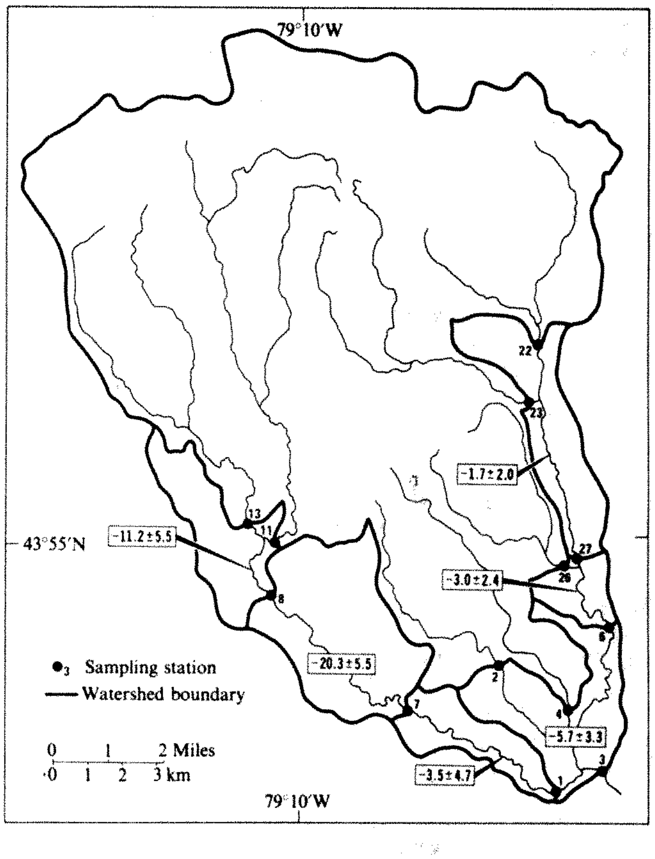

Fig. 1 Mean (±s.d.) daily losses of nitrate-N during low river flows in the late May–October period 1973–75 and 1978.

0028-0836/79/390291—02$01.00

251 mg m^{-2} of sediment surface daily for silt rich deposits and between 20 and 60 mg m^{-2} for samples with a high sand and gravel content. These rates of nitrate disappearance may provide an overestimate of denitrification losses because assimilatory nitrate reduction by bacteria was not evaluated. However, a recent laboratory investigation of sediments from streams in southern Ontario showed that 90–95% of the nitrate removal resulted from denitrification[5].

Nitrogen input–output balances were also measured for 10 days during the winter and spring months for the six downstream reaches of Duffin Creek. The data do not show any consistent pattern of nitrate-N removal, but this does not preclude the occurrence of denitrification. Small nitrate losses resulting from low rates of denitrification in cold temperature conditions would probably not be evident in the field data, owing to the range of error involved in the measurement of discharge and water chemistry.

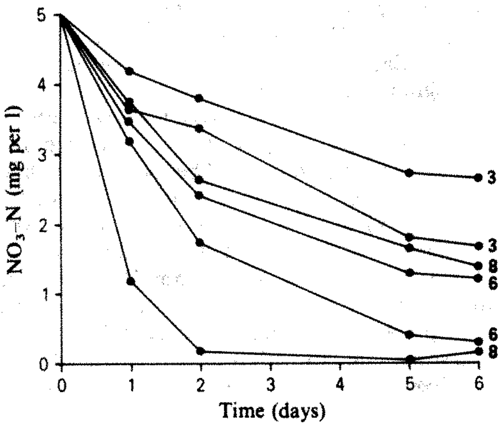

Fig. 2 Changes in nitrate-N concentration in water overlying sediment cores collected from sites 3, 6 and 8. The cores were incubated in the dark at a temperature of 20 °C. Air pumps were used to introduce bubles close to the water–sediment interface to reproduce the turbulence and aeration characteristic of river conditions.

The disappearance of nitrate-N was observed in 12 sediment–water profiles incubated at temperatures of 20 °C, 10 °C, 6 °C and 1 °C. From December to March the water temperature in Duffin Creek fluctuates between 0 and 2 °C. The laboratory data reveal that denitrification occurs in river sediments even at these low temperatures, although nitrate removal is only ~20% of the rate occurring at summer water temperatures which average 20 °C. River water temperatures range between 4 and 10 °C during November, April and early May. Water–sediment profiles incubated at 6 and 10 °C showed rates of nitrate loss which were 35% and 45% respectively of the nitrate removal at 20 °C. These results suggest that denitrification may occur in Duffin Creek during the winter and spring although at a much lower rate than is characteristic of late May to late October.

The field and laboratory data can be combined to calculate the annual removal of nitrogen by denitrification from the two main branches of Duffin Creek extending from sites 11, 13 and 22 to site 3 (Fig. 1). The 18 sets of field data collected between late May and late October indicate an average daily loss of ~45 ± 9 kg (s.d.) of nitrate-N for the combined six downstream river reaches. This daily rate of loss when adjusted to account for uptake by benthic algae and macrophytes would result in the removal of about 6,300 ± 1,250 kg of nitrate-N between 20 May and 31 October. Using the laboratory data on rates of denitrification at low water temperatures, it is estimated that an additional 2,000 kg of nitrate-N is lost between November and late May, producing a total annual removal of ~8,300 kg.

This calculation of annual nitrate-N removal ignores the possible effects of high river flows on denitrification. The occurrence of considerable disturbance and scouring of sediments during periods of storm flow probably creates aerated condtions which inhibit denitrification. The relationship between suspended sediment concentration and discharge at site 3 suggests that disturbance of the river bed sediment begins to occur at discharges greater than 2.83 m^3 s^{-1}. If it is assumed that denitrification is zero on days which have a mean daily discharge exceeding 2.83 m^3 s^{-1}, the annual removal of nitrate-N is reduced to about 7,300 kg.

The average annual export of nitrate plus nitrite-N from the Duffin Creek basin at site 3 for the period from May 1973 to May 1975 was ~73,000 kg (ref. 6). Measurements of Kjeldahl nitrogen concentrations are also available for the same period[4]. Calculations based on these measurements together with the daily river discharge records at site 3 indicate an average annual export of 62,000 kg Kjeldahl-N, giving a total nitrogen loss of 135,000 kg.

These observations allow an assessment of the importance of denitrification in relation to the nitrogen budget of Duffin Creek. The annual removal of 7,300–8,300 kg of nitrate-N in the downstream reaches of the river is ~5–6% of the annual export of total nitrogen from the river basin. This percentage must be regarded as tentative in view of the difficulty in estimating denitrification during the November to May period. Moreover, the budget technique used in this study cannot measure the denitrification of nitrate-N generated within bottom sediments: nitrates produced by nitrification in the oxidised surface layer of river sediment may subsequently undergo denitrification after diffusion to deeper anaerobic zones[7].

The importance of denitrification in relation to the nitrogen budget of Duffin Creek varies on a seasonal basis. Approximately 80% of the annual nitrogen exports from the river basin occur between November and April, when denitrification is negligible. However, denitrification is a major factor in the nitrogen budget of the creek from late May to October. Low river flows occur on approximately 140 days during these months each year. In these conditions there is an average daily removal of 45 kg nitrate-N in the downstream reaches principally due to denitrification. This loss represents 50% of the average daily input of total nitrogen and 75% of the nitrate-N input received by these channel reaches (A.R.H., in preparation).

The preservation or enhancement of denitrification in rivers has been viewed as a possible approach to the management of nitrogen in the environment[1,8]. These data suggest that this strategy would probably not produce a major reduction in the annual export of nitrogen from many drainage basins. However, benefits in the form of reduced nitrate-N concentrations in water and smaller nitrate exports to downstream ecosystems could be derived during low flow discharges in the warm seasons of the year.

I thank Drs J. B. Robinson and N. K. Kaushik for helpful discussions, W. Scott and Dr K. Sanmugadas for laboratory assistance, D. McLeish for field assistance and the cartographic staff in the Department of Geography for the figures. Anomalous propagation of seismic waves through the zone of shearing contact between converging plates of the New Hebrides arc

Remy Louat

Jacques Dubois

ORSTOM 24, Rue Bayard 75008 Paris and Laboratoire de Geophysique, Université Paris sud 91405, Orsay, France

Bryan L. Isacks

Department of Geological Sciences, Cornell University, Ithaca, New York, 14853

Results obtained from a network of five short-period seismograph stations operated for 2 months on the island of Santo in the central region of the New Hebrides provide evidence for the anomalous propagation of seismic waves through the zone of shearing contact between the converging plates of the New Hebrides Island Arc.

Santo Island has an abnormal position in the subduction zone, being located where the trench is usually found. The crustal blocks including Santo and Malekula Islands separate the New Hebrides Trench into a northern and a southern segment (see Fig. 1). The evolution of this anomalous morphology, and the relationship of it to the subduction of a major aseismic ridge, the *D'entrecasteaux* Fracture Zone, remain as interesting problems[1-5]. However, recent studies[6-9] show that the overall configuration of the Benioff zone is not now significantly contorted or disrupted through the central region of the arc. The inclined zone of thrust faulting or shear contact between the subducted oceanic plate and the island arc appears to be continuous along the entire length of the arc and is located at very shallow depths beneath the island of Santo (Fig. 2).

Thus a network on Santo is in a unique position in relation to the plate boundary, a position attainable in most other subduction zones only by the deployment of ocean bottom seismographs. In particular, a station on the west coast of Santo is seaward of the shallow zone of seismicity in such a position that it receives seismic waves which must pass through the zone of shearing contact between the plates. Stations in eastern Santo receive seismic waves which propagate mainly above the zone of contact, so a comparison of records obtained on Santo can show large anomalies in seismic wave propagation that might be associated with the zone of plate contact.

Five stations were operated on Santo as shown in Fig. 2. Earthquakes were located from arrival times of P and S waves. The accuracy of location is about ±5 km. The station on the

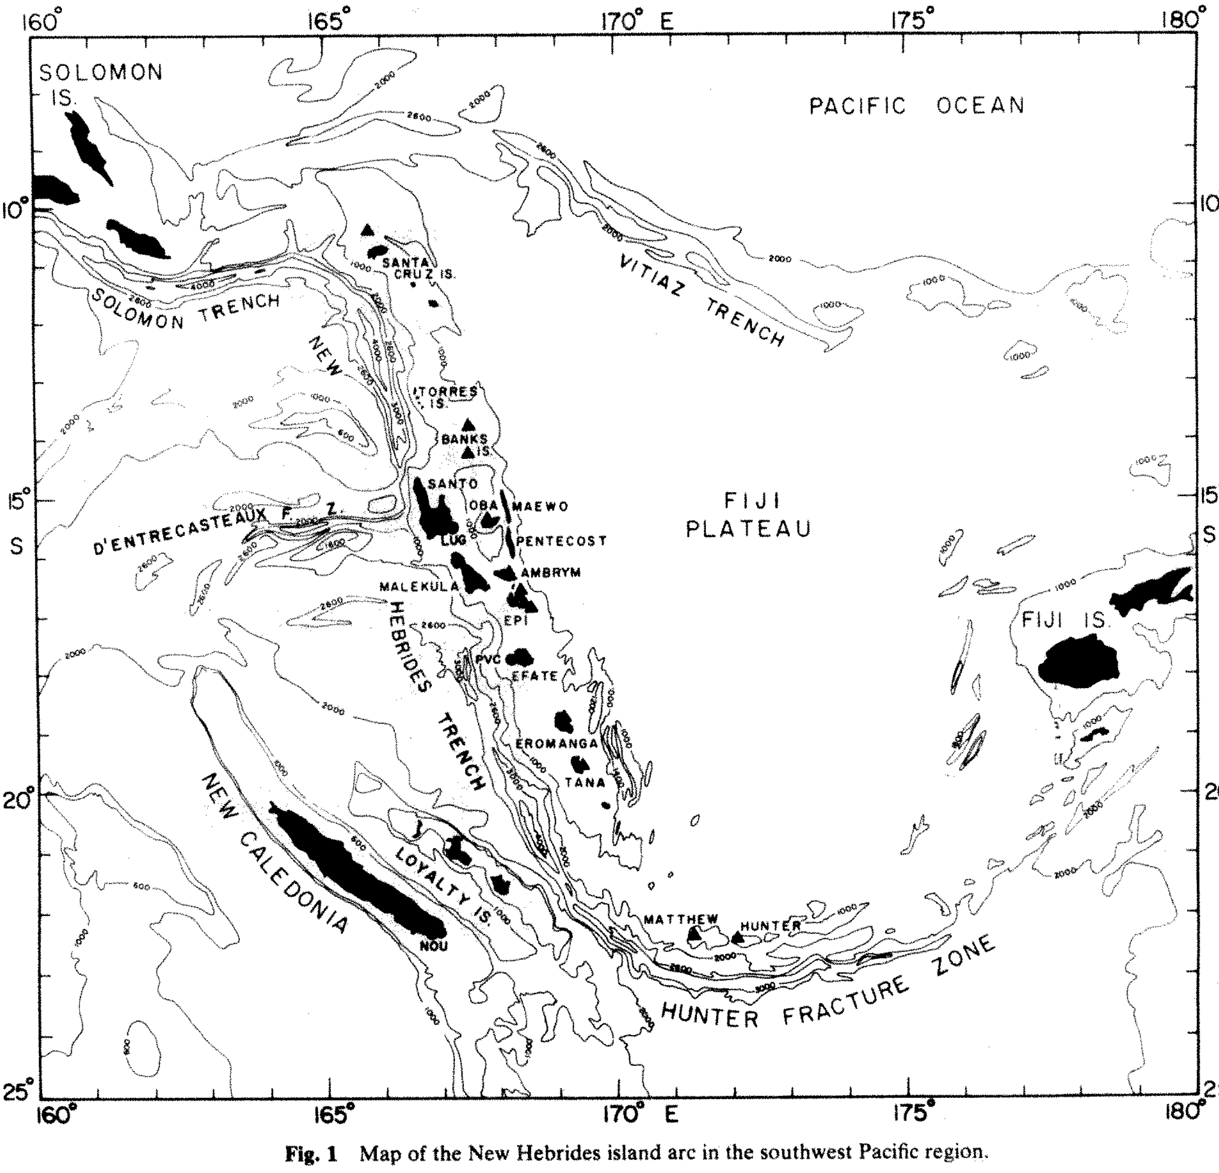

Fig. 1 Map of the New Hebrides island arc in the southwest Pacific region.

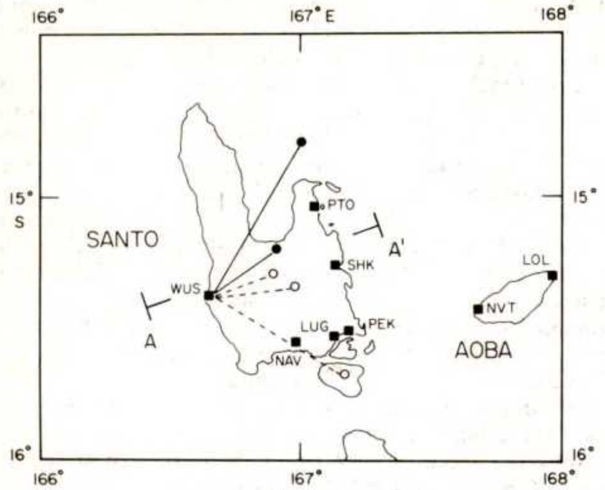

Fig. 2 Map of Santo and Aoba Islands showing temporary seismograph network operated in 1975. The three-letter abbreviations and solid squares indicate the seismograph stations. The solid and open circles show epicentres of the numbered earthquakes shown in Figs 4 and 5. Schematic ray paths to the station WUS are shown from those events. The dashed ray paths indicate low frequency shear waves at WUS.

west coast of Santo, WUS, operated for 10 days. The results for the period when WUS was recording are illustrated in Fig. 3. The dashed line is an approximation of the upper limit of the descending plate (see ref. 9). First motions of P waves from the cluster of events shown at shallow depths in Fig. 3 also indicate that the cluster is within the zone of plate contact. Events such as numbers 26 and 81 (Fig. 4) are reliably located beneath the thrust zone and are within the descending plate.

Although WUS recorded numerous events located beneath the thrust zone at intermediate depths, it clearly recorded only three of the events within the thrust zone (Fig. 3). As shown in Fig. 4, for two of the events (nos 79 and 88) the shear waves recorded by WUS have a frequency content remarkably lower than those from the same earthquakes recorded by stations PEK and SKB located in eastern Santo. The third event (no. 74) produces no clear shear waves at WUS, although the P wave is

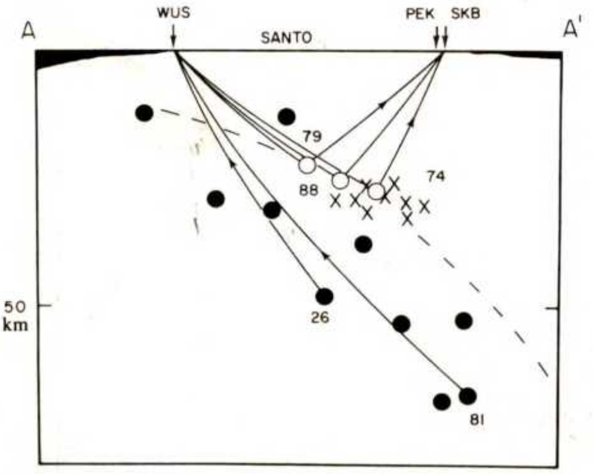

Fig. 3 Vertical section (see Fig. 2) showing events located during the 10-day period during which WUS was in operation. Crosses indicate events not perceptible on the WUS records, and circles indicate events recorded by WUS with (filled circles) or without (unfilled circles) high frequency shear phases. The ray paths are schematic and are not the result of quantitative ray tracing.

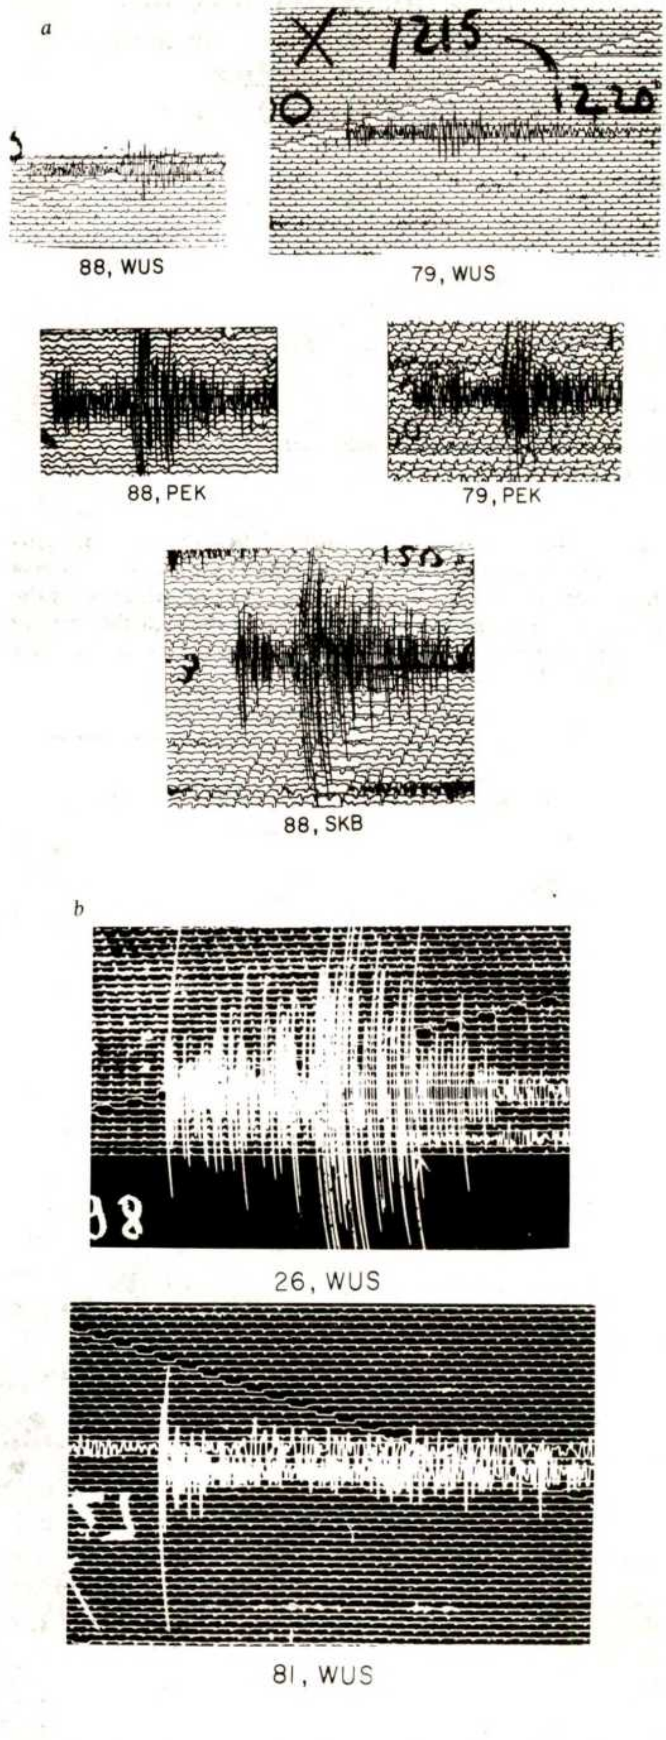

Fig. 4 *a*, Examples of seismograms from stations on Santo. The numbers and stations correspond to those shown in Figs 2 and 3. Second marks are clear on all records; the longer marks in certain records (for example, no. 79, WUS) are minute marks. *b*, Same as *a*, but showing different seismograms.

well recorded there, and high frequency shear waves are well recorded for this event in eastern Santo. In contrast, WUS records high frequency shear waves from events not within the shear zone (for example nos 26 and 81, Fig. 4), as do the other stations on Santo. The low frequency shear waves recorded by WUS for the two events in the thrust zone have predominant frequencies of 2 to 2.5 Hz, whereas the shear waves recorded by WUS for other events and by other Santo stations typically have predominant frequencies of 4 to 10 Hz.

Although the data are few, the combination of paths shown in Fig. 4 indicates that the unusual low frequency shear waves are not likely to be a localised effect near WUS. The anomalies must be a result of either a very special and unusual azimuthal variation in the radiation from the source, or, more likely, an effect of the propagation path. Results obtained so far raise the possibility that the shear waves to WUS suffer anomalously high attenuation within the zone of shearing contact between the converging plates of the subduction zone. The rays from earthquakes within the thrust zone must travel most of the way to WUS through or near the thrust zone. In contrast, rays from other events to WUS or from events within or beneath the thrust zone to other stations on Santo must only cross obliquely or pass above the thrust zone. If the removal of high frequency waves along the paths to WUS is by non-elastic dissipation, it may be possible to relate this to the development of a zone of viscous slip which is thermally activated by shear heating (as discussed by Yuen *et al.*[10]). However, Yuen *et al.* consider that such a zone would probably develop at greater depths and further down along the dip of the plate boundary. Alternatively, the attenuation may reflect scattering associated with heterogeneities developed within a zone of intense shearing. In either case, the zone should have a width sufficiently large to affect the passage of seismic waves.

Clearly further observations must be obtained. However, the data presented here suggest that useful information about the physical properties of a major earthquake-generating plate boundary may be obtained from suitably deployed local seismograph networks.

The five seismographic stations constituted part of a programme run by Cornell University and the Office de la Recherche Scientifique et Technique Outre-Mer (ORSTOM).

A Lower Carboniferous *Lepidodendropsis* flora in Kashmir

A. K. Pal

Geological Survey of India, 27 J.L.N. Road, Calcutta, India

W. G. Chaloner

Botany Department, Birkbeck College, University of London, Malet St, London WC1, UK

The concept of a more or less uniform world-wide flora (the '*Lepidodendropsis* flora') of early Carboniferous age, was first expounded by Jongmans[1]. He cited the fossil plant genera *Lepidodendropsis*, *Triphyllopteris* and *Rhacopteris* as characterising this palaeofloristic unit, of which he claimed representation from a number of Northern and Southern Hemisphere localities. Subsequent work has generally confirmed his conclusion that in the early Carboniferous a floristically rather uniform lycopod-rich association extended into all the major continents, preceding the onset of Carbo–Permian glaciation. In its relative uniformity this flora contrasts sharply with the pronounced regional character of the floras (especially the Gondwana *Glossopteris* flora) that followed the glaciation. Although representation of Jongmans' *Lepidodendropsis* flora was claimed for the major southern land masses (South America, Africa, Australia) only a very limited Carboniferous flora, of a few genera of fern/pteridosperm leaves, has been reported[2,3] from India. This flora, from the Thabo stage of Spiti, in the Western Himalayas, was the only Indian Carboniferous flora known hitherto, and it differed significantly from its counterparts in other parts of Gondwanaland in the absence of *Lepidodendropsis*, and indeed any other lycopods. A newly discovered flora of Lower Carboniferous age from the Gund Formation of Kashmir, some 400 km west-northwest of Spiti is reported here.

The Gund Formation comprises about 500 m of cyclic sediments consisting of conglomerates, sandstones and shales. It overlies unconformably the Syringothyris Limestone, regarded as of Tournaisian age on faunal grounds, and is overlain by the Fenestella Shale Formation of Upper Visean to Bashkirian age. It is thus securely bracketed as lying at least within the Lower Carboniferous[4].

The Gund flora contains several genera which link it with typical *Lepidodendropsis* floras from other parts of the world; it is dominated by a number of lycopods, particularly *Lepidodendropsis* (Fig. 1*b*), *Lepidosigillaria* (Fig. 1*c*), *Archaeosigillaria* and ?*Cyclostigma*, together with *Archaeocalamites* (Fig. 1*a*), *Rhacopteris* (Fig. 1*d*, *e*) and other sphenopterids. In these constituents the Gund flora shows significant agreement with the Early Carboniferous *Lepidodendropsis* flora from Europe, from the Pocono Formation of the US, and floras of comparable age in Peru, Ghana, Morocco, eastern Sahara and Egypt, Syria, China and western Malaysia. The common elements are shown in Table 1.

Jongmans[1] regarded his *Lepidodendropsis* flora as "the flora of the older part of the Lower Carboniferous and as the transition to the *Archaeopteris–Cyclostigma* flora of the true Upper Devonian". Note that in the Lower Carboniferous of Geigen Hof, Bavaria, where Lutz[5] first recognised *Lepidodendropsis hirmeri* (the type species), this genus occurs in association with *Rhacopteris* and various other sphenopterids, together with *Sphenophyllum*. Similar, more or less contemporaneous, floras are found in many parts of Europe with minor variations, such as the *Lepidodendropsis–Archaeocalamites–Rhacopteris* association of North Wales[6] or the *Lepidodendropsis–Archaeocalamites–Triphyllopteris–Rhodeopteridium* association of southern Spain[7]. Floras of the Pocono Formation in Pennsylvania and Virginia are strikingly similar to these, and comprise various species of *Lepidodendropsis*, *Cyclostigma*, *Triphyllopteris* and other sphenopterids[8]. A *Lepidodendropsis–Adiantites–Fryopsis* flora is known as far north as Alaska[9].

Comparable assemblages occur on the now separate parts of the Gondwanaland mass. A *Lepidodendropsis–Cyclostigma–Triphyllopteris–Adiantites–Rhacopteris* assemblage is known from Carhuamayo in Peru[10]. In Africa, *Lepidodendropsis* is reported from Ghana[11], and from Morocco[12] through Libya[13] and the eastern Sahara[14] to Egypt and Sinai[15,16], in association with one or more of the genera *Prelepidodendron*, *Archaeosigillaria*, *Lepidosigillaria*, *Archaeocalamites*, *Sphenopteris* and *Rhacopteris*. The early Carboniferous age attributed to Australian reports of *Archaeocalamites*, *Lepidodendron*, *Rhacopteris*, *Fryopsis* and *Adiantites* has been questioned[17]. In south-east Asia a *Lepidodendropsis–Sublepidodendron–Archaeocalamites–*

** Species in common; * Genus in common.

Triphyllopteris–Cardiopteris association is known from Wutung in Kianshi Province, China[18,19]. Further south a *Lepidodendropsis–Lepidodendron–Adiantites–Rhodeopteridium* assemblage occurs in the Lower Carboniferous of western Malaysia[20].

In the area east of the Urals floras occur that are characterised by several endemic genera of lycopods (*Ursodendron, Tomiodendron, Lophiodendron*) together with *Angaropteridium* and *Chacassopteris*[21]. While the separation of these several Russian genera may well be justified, the general aspect of these Lower Carboniferous Angara floras is broadly comparable to contemporaneous floras from other parts of the world[9].

Almost all known records of *Lepidodendropsis* are Lower Carboniferous in age, apart from two species reported from the Devonian of China[22], and the reports by French workers of this and other lycopod genera from the Devonian of North Africa. The reports from North Africa of several genera (*Lepidodendropsis, Archaeosigillaria, Tomiodendron, Abacodendron*) in rocks of Devonian age, considerably pre-dating their first occurrence elsewhere, has led to the suggestion[23] that Africa was the centre of origin of this whole group of arborescent lycopods (Lepidodendrales *sensu lato*). Until the age of the African material can be linked more securely with reliably-dated marine faunas this interpretation must be regarded as controversial.

The age of the Australian *Rhacopteris–Lepidodendropsis–Cyclostigma* flora, originally regarded[24] as Lower Carboniferous has more recently been reinterpreted as of Upper Carboniferous (Westphalian) age[17]. Such uncertainties in the age of pre-*Glossopteris* floras in Gondwanaland emphasise the significance of a flora such as that of the Gund Formation, in lying within a sequence containing marine faunas above it and below.

The Gund flora reported here confirms the close comparability of the Lower Carboniferous flora of northern India with that of other areas both in Gondwanaland and the (present) Northern Hemisphere. The four well-explored parts of the Gondwana block (India, South America, Africa and Australia) now prove to have had as close a floristic similarity before the Carbo-Permian glaciation, as that shown by the more intensively studied *Glossopteris* flora which succeeded it. A more detailed comparison of the plants of the Gund flora with those from other parts of Gondwanaland will be presented elsewhere.

Recent palaeomagnetic data from the Silurian and Devonian of China[25], has led Keppie[26] to divide Eastern Asia into two parts along a line through the Tien Shan-Mongol mountain belts to Vladivostock in his palaeogeographic reconstruction for the Devonian and Early Carboniferous. He was influenced in this proposal by the otherwise puzzling juxtaposition in the same latitudes of the Early Carboniferous Angara floral province with that of *Lepidodendropsis* in China. His reconstruction now places the boundary between these provinces at a palaeolatitude of approximately 35° N.

The present-day Chinese and Malaysian areas are brought in Keppie's reconstruction[26] into closer proximity to Gondwanaland than generally visualised hitherto, leaving their *Lepidodendropsis* flora disjunct from that of the main body of Eurameria. A somewhat more westerly position for the Sino-Malaysian block, possibly lying north and west of Australia, would offer a continuity with the *Lepidodendropsis* floras of Africa, South America and Europe, with this newly-discovered flora in Kashmir acting as a link between the eastern and western occurrences of *Lepidodendropsis*.

We thank the Royal Society for a Commonwealth Bursary, which made this joint research possible.

A gliding reptile from the Upper Permian of North East England

T. H. Pettigrew

Sunderland Museum, Borough Road, Sunderland, Tyne and Wear, UK

In July 1978 an unusual fossil reptile was discovered by D. Hall and myself 1.5 cm above the base of the Upper Permian Marl Slate at Eppleton Quarry near Hetton-le-Hole, Tyne and Wear (NZ 351484). The sapropelic Marl Slate, the first member of the English Zechstein succession, is a marine deposit well known for its fossil fish (mainly palaeoniscids) and land-derived plants[1]. The only recorded reptilian remains consist of two incomplete skeletons of *Protorosaurus*[2]. The new find is an incomplete skeleton (the skull, forelimbs and most of the tail have been destroyed by quarrying), 17 cm long, of a terrestrial reptile washed into the Zechstein Sea. It is especially interesting for its elongated and jointed dorsal ribs interpreted as an adaptation for the support of two membranes to enable the reptile either to parachute or more probably glide in a manner similar to the modern gliding lizard *Draco* of South East Asia[3].

The reptile is lying on its back and the bones, severely crushed by compaction of the clay matrix, are very fragile. The axial skeleton consists of 36 amphicoelous vertebrae comprising 13 constricted dorsals, 2 sacrals and 21 slightly constricted caudals. On the left side there are 21 elongated ribs, the last six of which articulate with the first six dorsal vertebrae. The remaining 15 ribs converge anteriorly towards the vertebral column until truncated by the edge of the rock slab in which the skeleton is embedded. From this it is evident that at leat 15 anterior dorsal vertebrae are missing, and an original pre-sacral count of at least 28 vertebrae is indicated.

All the ribs have a prominent ventral groove and the rib heads are weakly dichocephalous, articulating dorsoventrally with the centra by means of narrow 'shoulders'. Because they lie closely packed together and are partially superimposed, it is difficult to determine the relative lengths of the elongated ribs, although anteriorly they measure at least 130 mm. Several important features are visible on the left side, where each rib is interrupted by a break interpreted as a joint near the rib head (Fig. 1). These joints divide the ribs into a relatively short proximal end (articulating through the rib head with the vertebral column) connected (through the joint) to an extremely attenuated distal end tapered to a hair-like extremity. On the right side this relationship is almost obscured by the attenuated distal rib ends which are tightly folded back against the vertebral column (Fig. 1). The joints probably enabled the distal ends of the ribs, supporting the 'wings', to articulate in a horizontal plane either

0028-0836/79/390297—02$01.00

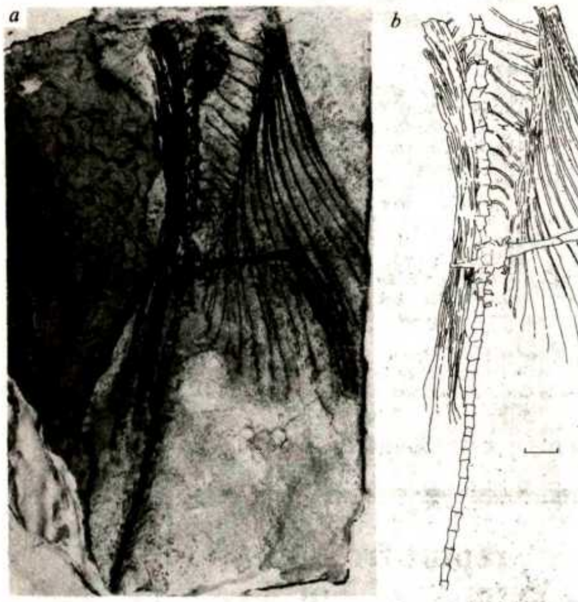

Fig. 1 Photograph (*a*) and sketch (*b*) of the reptilian skeleton from the Marl Slate of Hetton le Hole. Scale bar, 1 cm.

to spread them for gliding or to fold them back against the body for resting or walking. The thin, sinuous character of these ribs suggests they must have been fairly flexible and it is likely that, as in *Draco*, they were supported and pulled into shape by an elaborate arrangement of muscles and ligaments[3]. Behind these ribs are four short ribs also characterised by weakly dichocephalous rib heads.

Although the pelvis is crushed, a posteriorly directed iliac blade is visible. The left hind limb comprises a femur (27 mm long), fibula (18 mm long), tibia (19 mm long) and an elongate, clawed pes of which the tarsus and five digits have been crushed and splintered. The femur, tibia and fibula are relatively slender and thin walled. Of the right hind limb, preserved in counterpart, only fragments of the femur and an almost complete pes are preserved. Four broad-headed metatarsals are each 6 mm long. The fourth digit is 22 mm long with a deep and narrow claw. Several such claws are visible at the extremities of the digits of both right and left pes.

The Upper Permian Kupferschiefer is the European equivalent of the Marl Slate and in Germany has yielded three fragmentary skeletons of gliding reptiles. Only one, the holotype of *Weigeltisaurus jaekeli*, has been fully described[4,5], consisting of a well preserved skull with a partially disarticulated skeleton. The classification of *Weigeltisaurus* is uncertain and it has been variously placed in the subclass Lepidosauria order Rhynchocephalia[4], in the Lepidosauria order Weigeltisauridae[5] and in the subclass Euryapsida order Araeoscelidia[6]. Although similar to the Hetton reptile, it is larger and differs in the proportions of the skeletal elements. The two other (fragmentary) German specimens, pending a full description, have been tentatively referred to the genus *Weigeltisaurus*[7] but correspond in size and form more closely to the Hetton specimen. These three small reptiles are probably co-specific but their relationship to *Weigeltisaurus* is uncertain. There are about 15 species of the modern gliding lizard *Draco*, varying in size and weight from 5–6 g to 30 g in *Draco maximus*, the largest species[3]. By analogy, it is possible that the size range of the Permian gliding reptiles is attributable to different species of the genus *Weigeltisaurus*. Alternatively, they may represent sexual dimorphism within one species. Another gliding reptile, *Daedalosaurus madagascariensis*, has been described from the Upper Permian of Madagascar[8]. This poorly preserved lepidosaurian has 21 pairs of elongated ribs and shows both anatomical differences and similarities to the European reptiles. More research is required to clarify the classification and relationships of all these reptiles.

Similarly adapted reptiles include the Upper Triassic Kuhneosauridae, which possess 10–11 pairs of elongated ribs[3,9] and species of the aforementioned agamid lizard *Draco*, with 5–7 pairs[3]. The elongated ribs and other similarities of functional morphology can be related to the specialised ecology of these reptiles exemplified by *Draco*, an insectivorous form living aboreally in the rain forests of South East Asia[3]. Similar palaeoenvironmental conditions along the Zechstein Sea coasts are indicated by the diverse flora in the Marl Slate[1,10] and Kupferschiefer[11] which has also yielded insects[12,13].

I interpret the recurring adaptations in the Permian, Triassic and present-day gliding reptiles as the products of repetitive convergent evolution enabling exploitation of a highly specialised ecological niche.

I thank Alick Walker, Sue Evans and Beverly Halstead for assistance in the preparation of the script, and P. S. Davis and J. Holden for helpful discussion.

Negatively correlated cross-resistance to a synthetic pyrethroid in organophosphorus-resistant *Tetranychus urticae*

R. B. Chapman & D. R. Penman

Department of Entomology, Lincoln College, Canterbury,
New Zealand

Spider mites are serious pests of food and fibre crops and often cause considerable reductions in yields. Control is usually by regularly spraying chemicals, but frequently this approach has led to the development of resistance to these chemicals and ultimately to reduced levels of control[1–3]. A change to another chemical is then necessary. Most species of tetranychid mites of agricultural significance can develop resistance to many organophosphorus insecticides, some organochlorine and carbamate insecticides and various other compounds. Cross-resistance, where resistance to one compound confers resistance to other compounds of the same group, and multiple resistance, where resistance has developed to compounds from a number of structurally different groups, are also known to occur. Occasionally the development of resistance to one compound will have the reverse effect by making a population more susceptible to a newly introduced compound. This effect, termed negatively correlated cross-resistance, could have significant practical advantage in restoring some degree of susceptibility in a pest population. In this letter we describe an example of this phenomenon in spider mites in which resistance to organophosphates was linked with increased susceptibility to synthetic pyrethroids.

A strain of two-spotted spider mite, *Tetranychus urticae* Koch, resistant to an organophosphorus (OP) insecticide, was

Toxicity tests were performed by attaching 30 adult female mites to glass microscope slides with double-sided adhesive tape and immersing for 5 s in serially diluted solutions (5–7 concentrations) of the candidate insecticide. Solutions were prepared by dissolving technical grade samples (95%–99% pure) of fenvalerate and azinphos-methyl in an acetone: water (1:1) solvent. To determine solvent-induced mortality, mites were also immersed in solvent alone. Control mortality, which did not exceed 10%, was used to correct concentration-mortality data by Abbott's formula[8]. All dipping was performed at 25 ± 1 °C and 70–80% relative humidity for 24 h.

observed to be more susceptible to a synthetic pyrethroid (SP) insecticide than was a strain which had no history of exposure to insecticides. To confirm this observation populations of two-spotted spider mites from apple orchards in the Canterbury Province, New Zealand, were sampled for further laboratory tests. In these orchards the OP insecticide azinphos-methyl had been sprayed 5–10 times each year for many years to control lepidopterous pests. Spider mites in these orchards have become resistant to this insecticide. As a comparison, spider mite populations from home gardens where no sprays have been applied were also sampled for testing. The toxicities of azinphos-methyl and the SP insecticide fenvalerate were then determined by a standard laboratory slide dip technique[4]. Mortality was assessed after 24 h and the concentration–mortality data were subjected to probit analysis[5] to determine median lethal concentration (LC_{50}) values. Results for both insecticides are presented in Table 1 and Fig. 1.

Negatively correlated cross-resistance is clearly demonstrated, increasing azinphos-methyl resistance confering an increase in fenvalerate susceptibility. Populations of two-spotted spider mite with no history of exposure to insecticides were relatively more tolerant of fenvalerate than were field populations subjected to azinphos-methyl selection pressure. This phenomenon is uncommon among spider mites and has only been reported where resistance to the OP insecticide oxydemetonmethyl enhanced susceptibility to the formamidine compound, chlordimeform[6] and the carbamate insecticide formetanate[7]. Our results therefore suggest that by using fenvalerate a superior level of control could be achieved with azinphos-methyl resistant populations than with less resistant populations. The inclusion of fenvalerate in spray treatments in orchards where azinphos-methyl resistant mites abound may control these mites and eliminate the need for a specific acaricide. This would conserve the limited resource of effective chemicals.

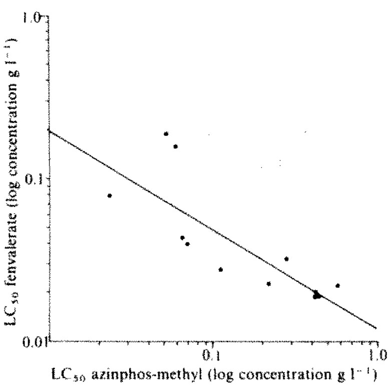

Fig. 1 Relationship between LC_{50} values of azinphos-methyl and fenvalerate for strains of two-spotted spider mite ($y = 0.011x^{-0.623}$; $r = 0.804$; $P > 0.01$).

We thank K. Jesson for techncal assistance and Shell Chemicals NZ Ltd for supplies of fenvalerate.

A virus which lyses the marine nanoflagellate *Micromonas pusilla*

J. A. Mayer* & F. J. R. Taylor†

Departments of Botany and Oceanography, University of British Columbia, Vancouver, British Columbia, Canada V6T 1W5

Observations of virus-like particles (VLPs) are now commonplace in a wide range of cell types. In most cases these observations represent incidental findings reported during a general ultrastructural investigation. Frequently in such instances it is impossible to establish the viral identity of the observed particles because the sample material containing the inclusions is no longer available and/or the data provided are inadequate. In particular, the number of established viral infections of algae[1,2] or protozoa[3] is small, and those amenable to continued study even smaller. We now report the isolation and ultrastructural identification of a lytic virus infecting the naked, marine phytoflagellate *Micromonas pusilla* (Butcher) Manton et Parke and describe its unusual mode of entry into the host.

---

* Present address: Research School of Biological Sciences, The Australian National University, PO Box 475, Canberra City, ACT 2601 Australia.
† To whom reprint requests should be addressed.

Micromonas pusilla is an extremely small (1.5 to 3.0 μm) photosynthetic flagellate which occurs widely in both coastal and oceanic waters and is occasionally present in large numbers (10^3–10^5 cells l^{-1})[4]. It is therefore a frequently overlooked but important member of the marine nanoplankton. *Micromonas pusilla* is usually considered to be an anomalous member of the Prasinophyceae[5,6]. Although plant-like in that it is photosynthetic, it lacks a cell wall.

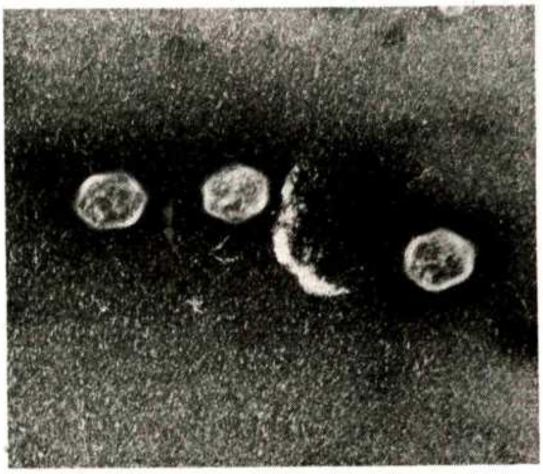

Fig. 1 Transmission electron micrograph of negatively stained MPV particles in clarified lysate from a culture of *M. pusilla*. ×76,500.

During a transmission electron microscope (TEM) study of natural communities of nanoplankton in the Strait of Georgia, British Columbia, in April 1975, polyhedral VLPs were observed within *Micromonas* cells from an enrichment culture of wild, mixed British Columbia nanoplankton. It was noted that *M. pusilla* disappeared rapidly from the enrichment culture and that medium from such a contaminated culture, after filtration through a 0.22-μm Millipore membrane filter, could cause lysis of a previously healthy unialgal culture. This infective filtrate caused the destruction of cultures of four unialgal strains of *M. pusilla* originating from both Atlantic and Pacific Oceans and maintained in the Northeast Pacific Culture Collection in the Department of Oceanography at the University of British Columbia.

Medium from lysed *M. pusilla* cultures was spun at 10,000*g* for 30 min to remove cell debris and negatively stained with 2% uranyl acetate. TEM examination of the clarified lysate revealed particles with hexagonal or pentagonal outlines measuring 130–135 nm in diameter (Fig. 1). No tail-like structures or other external appendages were observed.

The clarified lysate was inoculated into actively growing cultures of *M. pusilla* (whose cells, when examined with TEM,

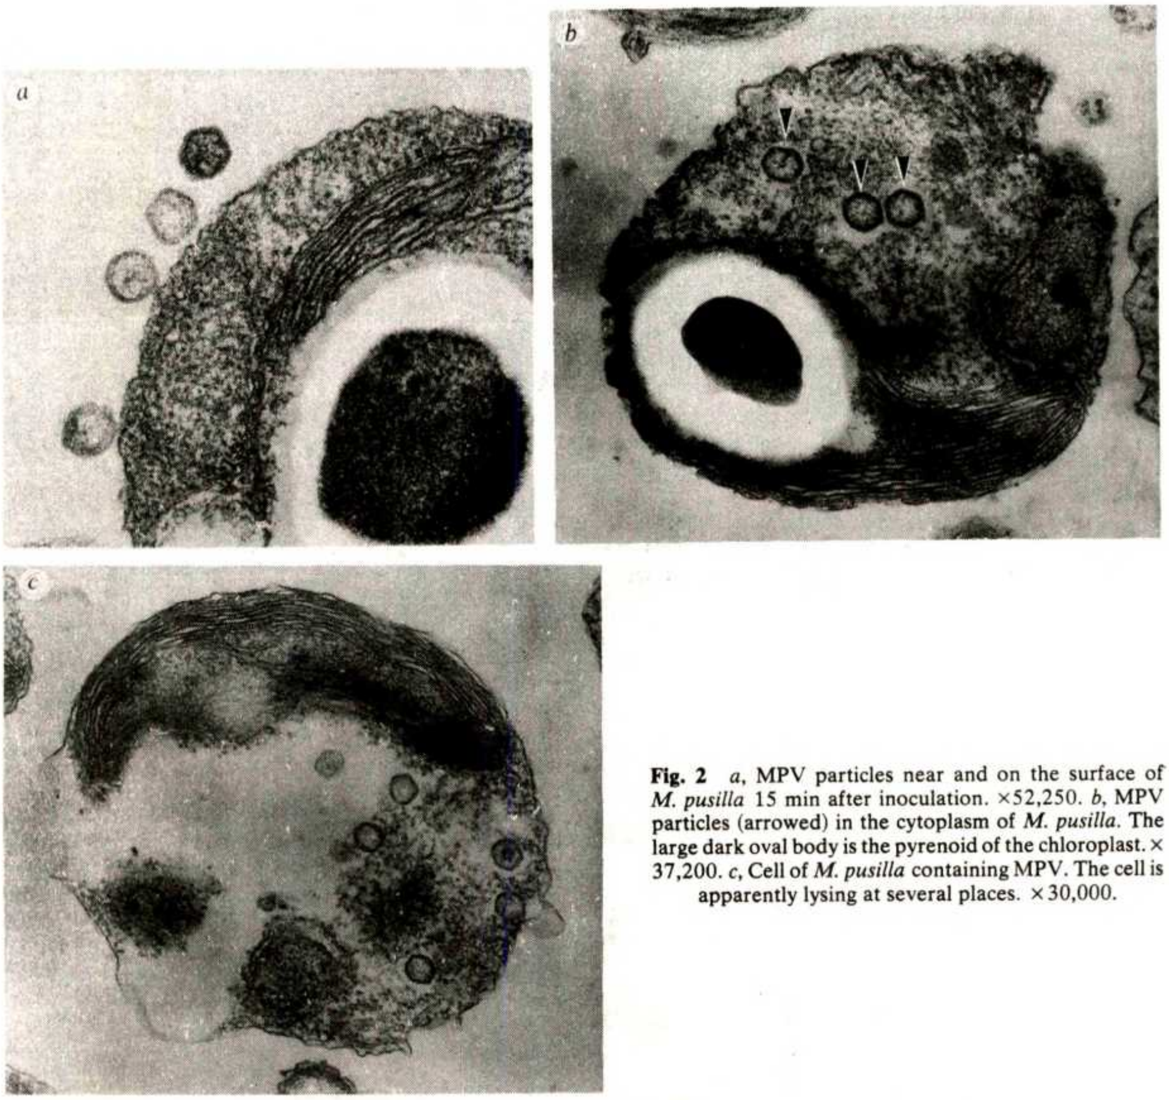

Fig. 2 *a*, MPV particles near and on the surface of *M. pusilla* 15 min after inoculation. ×52,250. *b*, MPV particles (arrowed) in the cytoplasm of *M. pusilla*. The large dark oval body is the pyrenoid of the chloroplast. × 37,200. *c*, Cell of *M. pusilla* containing MPV. The cell is apparently lysing at several places. ×30,000.

did not exhibit particles). Ultrastructural examination of these cultures indicated a predictable series of events. (1) Within 15 min polyhedral particles adhere to host cell surfaces (Fig. 2*a*). This localised attachment is followed by the fusion of adjacent host and particle surfaces, establishing confluence between the particle core and host cytoplasm. Particle entry by host phagocytosis (viropexis) was never observed. (2) Early stages of interaction described above are followed by an 'eclipse period' of approximately 3 h. Cells examined during this interval demonstrate no ultrastructural peculiarities. (3) Progeny particles appear within the cytoplasm (Fig. 2*b*). Their appearance is associated with the production of large amounts of scattered cytoplasmic fibrils (~5–8 nm in diameter) and clusters of small, membrane-bound vesicles never present in 'healthy' cells. Particles were never seen within the nucleus or associated with specific cell organelles. The *in situ*, sectional views of the particles are similar in shape and size to those observed in negatively stained preparations of the isolated particles. (4) Progeny particles are released by localised rupture of the cell membrane, often seen at several locations in the same cell, the cell contents including the particles being released into the medium (Fig. 2*c*).

Regularly shaped, polyhedral, intracellular structures, first observed in a naturally occurring population of *M. pusilla*, have been isolated and described. We conclude that the following evidence is sufficient to establish the viral nature of these entities. First, the particles can be introduced into and cause lysis of four geographical isolates of *M. pusilla*. Second, the particles pass through a 0.22-μm filter. This filtrate causes lysis as described above. Third, the morphology of these particles is similar to that of known viruses, and finally, the location of the particles relative to the time from introduction until cell lysis is consistent with that of a viral infection.

The particles have been tested with 46 planktonic algal isolates representing 35 species from 5 classes. Lysis occurred only in the four isolates of *M. pusilla*. The virus has been designated '*Micromonas pusilla* virus' (MPV).

This is the first case of controlled viral destruction of a marine phytoplankton organism known to us. Freshwater cyanophyte phytoplankters have been reported to be destroyed by 'cyanophages'[7]. The infection of these walled prokaryotic hosts resembles bacteriophage activity and is quite different from that of the small naked eukaryotic cells described here. The mode of entry of MPV seems unlike any virus previously described. MPV also differs from other algal viruses in that penetration through a cell wall is not required. As the virus is known to occur in natural seawater, at least in British Columbia and neighbouring Washington state[8], the ecological effect of MPV virus on the population dynamics of *M. pusilla* should be investigated.

As characterisation of MPV has not been completed, the group of viruses to which it belongs is unknown. On the basis of its large size, general morphology and apparent cytoplasmic site of assembly, MPV resembles a large number of viruses which have been referred to collectively as icosahedral cytoplasmic deoxyriboviruses[9,10] or the Iridoviridae[11]. This group of viruses is characterised in part by the presence of a DNA genome and by the iridescent appearance of crystals formed within their multicellular hosts or pellets of centrifuged virus. The definitive relationship of this newly identified viral pathogen with known virus groups can be determined only after information on its biochemical and biophysical properties becomes available.

Rapid deposition of subcutaneous areolar tissue in response to sexual stimulation in mice

F. H. Bronson

The Institute of Reproductive Biology, Department of Zoology, University of Texas, Austin, Texas 78712

Many of the reproductive processes of house mice are regulated exteroceptively by social cues[1]. Puberty in a female mouse, for example, is a labile event that can be accelerated markedly if the young female is housed with an adult male[2]. The relevant male stimuli in this case are a combination of pheromonal and tactile cues[3–5]. The female's responses to these cues include an immediate, sequential release of gonadotropic and ovarian hormones[6], which in turn evoke a series of predictable changes in most of the female's reproductive tissues and culminate in the pubertal ovulation. I report here an unexpected consequence of exposing a young female mouse to a male, namely an intense response of a non-reproductive tissue. Specifically, young female mice experience a rapid thickening of their subcutaneous areolar tissue when they are exposed to males. The proximal cause of this response seems to be largely, but not exclusively, an enhanced secretion of ovarian oestrogen.

The phenomenon is illustrated in Fig. 1. In these preliminary experiments, CF1 female mice were weaned at 21–24 d and immediately housed in a room free of males. When they weighed 16–17 g, the females were either regrouped in the same room or paired individually with adult males in another room, a standard procedure for studying the socially induced acceleration of puberty in mice[2,6]. All females were killed after 3 d of such housing. Samples of skin (1 cm^2) were removed from the back of each female, fixed in formalin and stained with haematoxylin and eosin. The examples presented in Fig. 1 are typical of the results. The subcutaneous tissue in all 10 females exposed to males was 5–20 times thicker than that of any of the 10 control females. This thickening seemed to occur under the skin on all parts of the body but was studied in detail only on the back.

Many types of connective tissue are known to be sensitive to steroids of ovarian and/or adrenal origin[7,8], although the areolar tissue under the skin seems to have been routinely ignored in such studies[9]. A second experiment therefore examined the possible role of the ovary as a mediator of the socially enhanced deposition of areolar tissue. A group of 16 females (15–16 g) was ovariectomised or subjected to sham operations. Following 3 d of recovery, these females were either paired with males or housed in groups in a room free of males. Dorsal skin samples

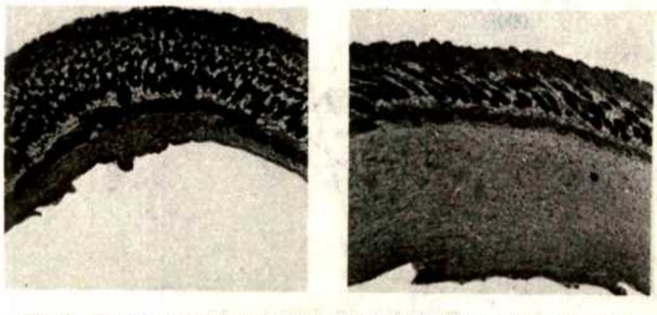

Fig. 1 Sections of skin taken from the backs of young female mice after the animals had been kept in groups in a male-free room (left) or individually paired with a male for 3 d (right). The thicker layer of subcutaneous connective tissue underlying the skin in the section on the right is obvious. The difference in thickness of the cutaneous layers themselves is not related to any experimental variable; such variation between individuals is normal for this stock of mice.

Table 1 Changes in thickness of subcutaneous areolar tissue and mean uterine weight in young female mice following ovariectomy

	Areolar tissue (μm)		Uterine weight (mg)	
	Ovx	Sham	Ovx	Sham
Male-exposed	142±7	1,602±111	10±1	115±8
Grouped	99±2	109±8	11±1	23±3

The female mice were ovariectomised (Ovx) or sham operated and then either exposed to males or held in groups for 4 d ($n = 4$ in each case). The results are the mean±s.e.

were collected 4 d later and sectioned on a cryostat; the thickness of the areolar tissue was estimated in repeated samples with a micrometer eyepiece. The results in Table 1 show an average 15-fold increase in the thickness of this tissue in those sham-operated females exposed to males. This response to a male was largely but not entirely eliminated by ovariectomy. Table 1 also records some basic differences between subcutaneous connective tissue and the uterus with regard to their relative responsiveness to ovariectomy and male stimulation. Exposing a young female mouse to a male results in a sequential release of luteinising hormone from the pituitary and oestradiol from the ovary[6]. The uterus gains weight rapidly in response to the enhanced secretion of oestradiol and, as shown in Table 1, ovariectomy completely abolishes such male-induced growth of the uterus but is not completely effective in blocking the deposition of subcutaneous areolar tissue in response to male stimulation. Furthermore, the uterus is markedly and significantly ($P < 0.01$) smaller 4 d after ovariectomy whereas the increase in the thickness of subcutaneous areolar tissue at this time is not significantly depressed by ovariectomy.

The results of a series of pilot studies, each of which involved the injection of steroid or pituitary hormones, suggested that the female mouse's subcutaneous connective tissue is strongly responsive to oestradiol but not to several other hormones, including progesterone and ACTH. Figure 2 shows a dose–response curve of areolar tissue thickness in young females implanted with various doses of oestradiol. These females were ovariectomised at 15–16 g and allowed 3 d to recover, after which they were implanted with hormone. Oestradiol implants were made by mixing 17β-oestradiol with Silastic adhesive (Type A, No. 891, Dow Corning). The resulting suspension was packed in a 10-mm Silastic capsule (i.d. 0.04 mm; o.d. 0.085 mm, Dow Corning). A suspension of 0.1 mg oestradiol per ml resulted in a significant thickening of the areolar tissue ($P < 0.01$) although the uterus was unresponsive to this dose of oestradiol. Both the uterus and areolar tissue responded strongly to doses above 0.1 mg ml^{-1}. With 10 mg ml^{-1} there was slightly more deposition of areolar tissue than occurred after 4 d of male exposure in an intact female (see Fig. 2 and Table 1).

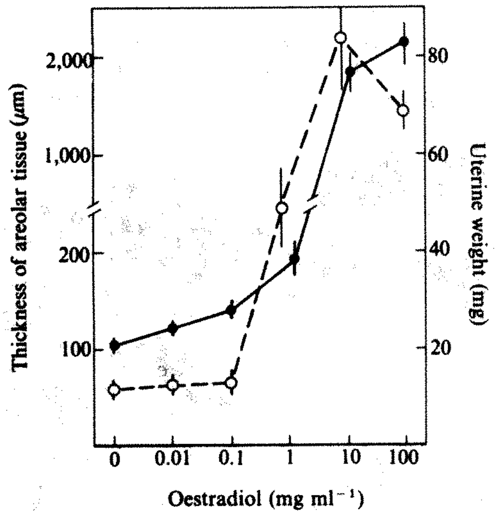

Fig. 2 Mean thickness of subcutaneous areolar tissue (μm±s.e.) (●) and mean uterine weight (mg±s.e.) (○) in young female mice that were ovariectomised and implanted with Silastic capsules contaning oestradiol.

What might be the adaptive function of the deposition of this layer of subcutaneous tissue in response to a male? This layer of connective tissue does not anchor the skin to the underlying musculature in the mouse, as it does in some other mammals[10]. Despite the total absence of fat cells in this tissue when under the skin of the back (Fig. 1), it is impregnated with fat cells in the area of the mammary glands, but the preponderance of such cells does not seem to change at puberty. Thus, one would not expect the pubertal increase in this layer of connective tissue to be important for post-pubertal steroid metabolism or thermal insulation. One possibility is that, as this layer of connective tissue envelops the mammary glands ventrally, its thickening in response to oestrogen could be a provision for the support of these glands when they enlarge during late pregnancy, and could subsequently serve to anchor them firmly to the skin during lactation. Whatever the function for this tissue response, however, the present results do show that in the mouse this tissue is an important target of oestrogen action, and is perhaps even more sensitive to oestrogen than the organ best recognised as a target for this steroid, the uterus.

I thank Dr Gregory J. Raugi for advice, and Shirley Beckwith and Walter Scribner for technical help. This research was supported by USPHS grant HD03803 from the National Institute of Child Health and Human Development.

Resistance of mice suppressed for IgM production to *Babesia microti* infection

Yvonne J. Rosenberg & Charles B. Evans

Laboratory of Microbial Immunity, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20205

The immunological mechanisms responsible for overcoming infections with *Babesia*, an intra-erythrocytic protozoan, are not fully understood. Although high titres of specific anti-babesial antibodies have been observed in several species of animals[1], and protection has been obtained by transfer of large volumes of recovery serum[2], the role of antibody in the immune response to an infection is uncertain. The present study investigates the nature of B-cell participation during *Babesia microti* infections by observing the course of the disease in mice in which IgM production has been suppressed from birth and which contain no B cells. The results show that, in contrast to control mice, which develop and subsequently clear circulating parasitaemias, suppressed mice show an unexpected resistance to infection as reflected by a virtual absence of parasites in the peripheral circulation.

Three-month-old female B6CF$_1$ mice injected from birth with either GαMIgM (group 1) or goat anti-ferritin antibody (group 2), or untreated (group 3), were infected i.p. with 10^6 *B. microti* and per cent parasitaemias for each mouse determined by Giemsa stain. Suppressed mice were still negative for circulating IgM when tested by Ouchterlony analysis 29 days after infection. Removal of suppression at day 30 did not result in the appearance of parasites in peripheral smears 7 or 14 days later. On day 37, blood samples from the five remaining suppressed mice were subinoculated into B6CF$_1$ normal mice. Three of the recipients had low parasitaemias at day 12 after sub-inoculation.

*Homologous immunity was tested on day 53 by infection of all groups with 10^6 *B. microti* and smeared on day 7 (D60) and day 14 (D67) thereafter. Six months after challenge, groups 1 and 2 received 10^6 *P. yoelii* i.p. 90% Of mice died within 10 days. ND, not done; D, died.

†Died day 29.

The following three age-matched groups of (C57BL/6 × BALB/c)F$_1$ (B6CF$_1$) and BALB/c × C57BL/6)F$_1$ (CB6F$_1$) mice, each containing 4–10 animals, were intraperitoneally (i.p.) infected with 10^6 *B. microti* (Kings 67 strain): (1) mice suppressed from birth with a globulin fraction of goat anti-mouse IgM (GαMIgM)[3], and which showed no circulating IgM at the time of infection (suppressed group); (2) mice which received a globulin fraction of goat anti-ferritin antibody in a similar injection regime, to control for any effects of repeated antibody injections (antibody controls), and (3) normal, untreated mice (normal controls). Parasitaemias, determined by Giemsa stain of thin smears from tail blood, were first examined at various times after primary infection with *Babesia*, again in the succeeding interval during which the IgM suppression was discontinued, and finally, following challenge with the same parasite. Thereafter, immunity to a heterologous parasite was tested by infection with 10^6 lethal malaria (17 × *Plasmodium yoelii*). The data from two such experiments, which compare the per cent parasitised erythrocytes observed in the periphery of suppressed versus both control groups, are presented in Tables 1 and 2.

Results from the first experiment, which used 3-month-old B6CF$_1$ female mice throughout, are shown in Table 1. As can be seen, in contrast to the rise and fall in parasitaemias observed in either control group, the suppressed group showed a virtual absence of parasitised red blood cells (RBC) in the circulation (except for one mouse which had 9.6% of cells infected). Although this apparent lack of parasites continued when mice were released from suppression, low numbers must have been present, as three out of five of the remaining suppressed mice were positive on sub-inoculation 37 days after infection. Despite the fact that parasites were rarely seen in the suppressed mice following primary infection, these animals nevertheless seemed to be as well protected as control mice against homologous challenge 7 weeks later. In addition, both the suppressed and control groups exhibited a lack of heterologous immunity after infection with lethal *P. yoelii* several months after primary infection with *B. microti*. These findings are similar to those of Cox using non-lethal *P. yoelii*[4].

It is possible that the coating of parasitised cells in recipient mice by GαMIgM either directly, or indirectly through passively transferred IgM on infected cells, could have resulted in blocking of infection by parasites or rapid clearance of infected cells by macrophages in the suppressed mice. To test for such effects, the parasitised cells used in the second experiment were washed three times in saline before infection and, in addition, a portion of these washed cells was incubated in GαMIgM serum for 30 min at 4 °C before injection into normal mice, to examine whether cells deliberately coated with Ig were rendered non-infectious. In this experiment, 2-month-old B6CF$_1$ mice (suppressed and antibody control groups) and CB6F$_1$ mice (normal group) of both sexes were used, and four normal 4-month-old female B6CF$_1$ mice also served as controls.

The results, presented in Table 2, are similar to those obtained in the first experiment in that (1) suppressed mice showed almost no sign of parasites compared with the controls, (2) removal of suppression had no effect on the levels of parasitaemia, and (3) the degree of protection on challenge was similar in each group. The differences in parasitaemia between the antibody and normal control groups which occurred in the first experiment were not seen in experiment 2. The lower peak of parasitaemias seen during the second experiment, however, probably reflects the fact that these mice were 4 weeks younger than those used in experiment 1, as the 4-month-old normal control mice developed much higher parasitaemias with the same inoculating dose. These results also suggested that at least in the younger mice, a sex-related susceptibility to infection with *B. microti* exists, as male mice always had higher parasitaemias than females. Furthermore, the preincubation of the parasitised cells in GαMIgM did not affect the ability of the parasite to infect and multiply, but rather resulted in consistently higher parasitaemias (Table 2). As in experiment 1, all mice were equally protected following reinfection with *B. microti*, although low parasitaemias in recipients of sub-inoculated blood from all groups indicated that low levels of infection persisted after homologous challenge. As an additional control for the effects of GαMIgM injections, an experiment was done in which normal adult

B6CF$_1$ mice were given the antisera for 8 days before and 22 days after infection with 10^6 *B. microti*. These mice developed parasitaemias similar to those seen in normal control mice.

Previous studies have suggested that an intact complement system is essential for the development of Babesial parasitaemias[5,6], and more recently, Chapman and Ward[7] demonstrated that factors of the alternate pathway as well as the third (C3) and fifth (C5) components from human or rat serum are required for *Babesia rhodaini* penetration of human red cells *in vitro*. As it was possible that the absence of parasitaemia in IgM-suppressed mice reflected a deficiency in the required complement components, serum samples from these animals were tested for C3 activity by immune adherence[8]. This assay uses the fact that human erythrocytes which have a receptor for the third component of complement (C3b) will adhere to sensitised sheep RBC preincubated in serum containing C3 components (as well as C1, C4 and C2). The results (not shown) indicated that the C3 titres in three suppressed mice were in the same range as those in the three control mice and makes it unlikely that a C3 deficiency could explain the above results.

Based on the present data, the simplest explanation for the apparent lack of susceptibility to infection of suppressed mice is that, to invade mature RBC, *Babesia* parasites require IgM antibody; the absence of the capacity to make IgM antibody thus confers resistance. Although the specificity of such an antibody is not known, an interesting possibility is that an autoantibody with specificity for membrane determinants on parasitised or normal erythrocytes is required for invasion. Antibodies reactive with antigens on enzyme-treated isologous RBC have been demonstrated during protozoal infections[9,10] and are also elicited following infection of normal mice with *B. microti* (not shown). Perhaps, therefore, red cell antigen–antibody complexes in association with complement facilitate penetration of the parasite into erythrocytes by alteration of the red cell membrane.

However, several other interpretations of the data are possible. For example, because only peripheral smears were examined, parasites sequestered in specific organs would not have been scored. In addition, the observed resistance might be explained by increases in the activity of natural killer (NK) cells[11,12] or macrophages in the suppressed mice. A protective role for such cells, however, is not compatible with the studies of Weinbaum *et al.*[13] which demonstrate the ability of another non-lethal parasite, 17X *P. yoelii*, to infect and eventually kill similarly suppressed mice. It is not known whether the mechanisms preventing a primary parasitaemia are the same as those which result in protection on challenge. Thus, although IgM suppression could explain the lack of parasitaemias following the initial infection, it is possible that T cells primed by the few parasites present during that time are effective in protecting mice after suppression is discontinued[14]. For this reason, the present observations probably reflect the existence of several different mechanisms responsible for the protection observed in the IgM-suppressed mice, some of which may be similar to those resulting in the phenomenon of age resistance in young cattle[15].

Male and female 2-month-old B6CF$_1$ mice (IgM-suppressed and antibody control groups) and CB6F$_1$ mice (normal controls) were infected with 10^6 *B. microti* i.p. and parasitaemias determined by Giemsa stain. Data are expressed as mean per cent parasitaemia in each group. The range for each group is given in parentheses. All parasitised RBC were washed three times in saline before injection.

* All groups were challenged on day 103 with 10^6 *B. microti*.

† Washed parasitised RBC were preincubated in GαMIgM for 30 min at 4 °C before injection.

‡ Four-month-old normal B6CF$_1$ controls.

We thank Dr Michael Frank and Ms Thelma Gaither for assistance with the complement assays, and Drs Richard Asofsky, Louis Miller, David Wyler and Gerald Cole for reading the manuscript.

Cross-linking of lymphocytic surface immunoglobulin inhibits its production via a cyclic nucleotide mechanism

M. Glennie, F. K. Stevenson, G. T. Stevenson & M. Virji

Tenovus Research Laboratory, Southampton General Hospital,
Southampton, UK

When antibody to immunoglobulin (anti-Ig) reacts with Ig molecules on B-lymphocyte surfaces the Ig, tethered by the antibody, moves over the surface to form patches and finally a cap at one pole of the cell. Simultaneously, the Ig–antibody complexes are removed by pinocytosis at the patches and cap, until the surface is cleared of the target molecules[1,2]. In immunofluorescent studies, Sidman and Unanue[3] followed the reappearance of the surface Ig during subsequent culture of the cells. They observed that splenic lymphocytes from adult mice re-express surface Ig promptly, whereas those from neonatal animals re-express poorly or not at all. They suggested that this phenomenon might be related to the greater susceptibility of lymphocytes from immature animals to tolerisation by antigen. Such an interpretation was supported by a simultaneous study[4] showing that explanted mouse fetal lymphocytes were less able to re-express surface Ig after treatment by anti-Ig than were adult lymphocytes. However, Ault and Unanue[5] later reported in man a similar dichotomy between blood and nodal lymphocytes, the former re-expressing surface Ig more poorly. We report here studies on guinea pig leukaemic lymphocytes, which have also shown delayed re-expression of surface Ig after clearing by antibody. We present evidence that the delayed re-expression reflects a reduction in the normal delivery rate associated with turnover at the surface. The reduction follows a train of events initiated by cross-linking of the surface Ig and including an increase in intracellular cyclic AMP. Furthermore, the shutdown in delivery is apparently specific, inasmuch as delivery of two other surface molecules we have been able to quantify proceeds unimpeded. These observations suggest a basic mechanism expressed to varying extents by normal lymphoid populations to account for their differing rates of surface Ig regeneration[3–5].

The L_2C leukaemia arose spontaneously in a female strain 2 guinea pig and has since been maintained by passaging *in vivo* through syngeneic or near-syngeneic animals[6]. Cells for the present work were collected from the blood of animals in the terminal stages of the disease[7]. The cells show a surface chemistry typical of B lymphocytes[8]. The surface Ig is of class IgMλ with a density of approximately 50,000 molecules per cell and a half life on the surface of about 5 h (ref. 9).

The general experimental plan was to perturb the surface Ig of the L_2C cell in culture at 37 °C, by antibody or other means, to chill the cells, remove the perturbing agent and wash, and then to culture the cells again, sampling at intervals to determine the density of the Ig or other surface molecules. The anti-Ig used was raised in sheep against the C_λ determinants of guinea pig Ig, and was purified by affinity chromatography[10]. Antibodies to the histocompatibility antigens Ia(2,4) and GPLA(B1) were raised in guinea pigs: anti-Ia by injecting strain 13 animals with normal strain 2 splenic and nodal lymphocytes[11], and anti-GPLA by injecting Dunkin–Hartley animals (lacking GPLA(B1) on testing with an antiserum and matching strain 13 in Ia to the extent that testing was possible) with normal strain 13 lymphocytes. Estimations of the densities of L_2C surface molecules were carried out by allowing the cells to react at 4 °C with isotopically labelled antibody. The surface Ig was labelled directly by ^{125}I-Fab′γ prepared from purified anti-C_λ, the Ia and GPLA antigens indirectly by incubating first with IgG from the corresponding guinea pig antiserum and then, after an intermediate washing, with ^{125}I-labelled purified sheep anti-(guinea pig Fcγ). Antibody concentrations were on the plateaus of previously defined labelling curves. Labelling of controls by non-antibody Fab′γ or IgG was always negligible.

Figure 1*a* shows that the L_2C surface Ig is turning over with a half life of 5 h: this is demonstrated both by the rate of re-appearance of its Fab regions after their removal by papain (leaving the Fc regions attached to the membrane[12]), and by the

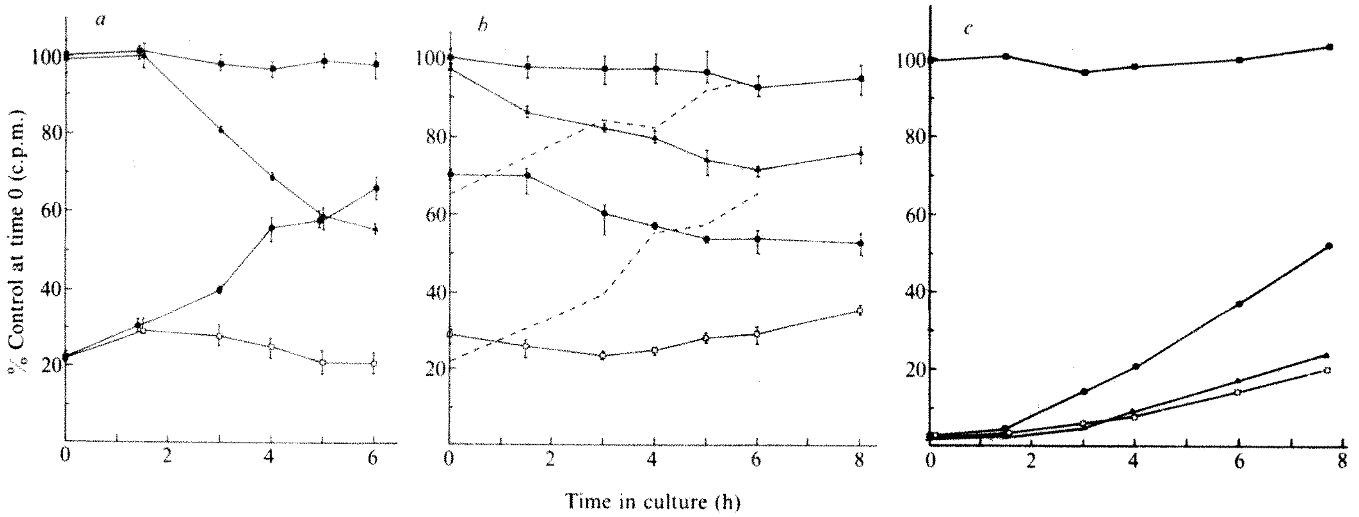

Fig. 1 Densities of surface Ig. After the treatments described below the cells were cultured with swirling at 37 °C in supplemented Eagle's medium (5 × 10^6 cells ml^{-1}), and were sampled at intervals to quantify the surface Ig by labelling with radioactive anti-Ig. The ranges shown are of triplicates. *a*, Normal turnover. ■, Control cells, treated as for the papain digestion but with the enzyme omitted; ●, treated with papain 0.1 mg ml^{-1} and dithiothreitol 0.1 mM for 30 min at 37 °C; ▲, treated as the controls, then cultured in the presence of 0.1 mM cycloheximide; □, treated with papain and dithiothreitol, then cultured in the presence of 0.1 mM cycloheximide. *b*, Reduced delivery following treatment with anti-Ig. Cells were exposed to sheep IgG at 50 μg ml^{-1} for 30 min at 37 °C before washing and culturing. The sheep IgG contained anti-Ig antibody at the following concentrations: ■, zero; ▲, 1 μg ml^{-1}; ●, 8 μg ml^{-1}; □, 50 μg ml^{-1}. - - - -, Parallel batches of cells treated with papain at 0.01 mg ml^{-1} (upper line) or 0.1 mg ml^{-1} (lower line), without exposure to antibody. *c*, Confirming reduced delivery due to anti-Ig. The sequential treatments were each of the same duration as in *a* and *b*, and were carried out with chilling and washing after each step. ■, Treated with normal IgG 200 μg ml^{-1}, followed by papain-free buffer; ●, treated with normal IgG 200 μg ml^{-1}, followed by papain 0.1 mg ml^{-1}; □, treated with anti-Ig 200 μg ml^{-1}, followed by papain-free buffer; ▲, treated with antibody 200 μg ml^{-1}, followed by papain 0.1 mg ml^{-1}.

0028-0836/79/390305—03$01.00

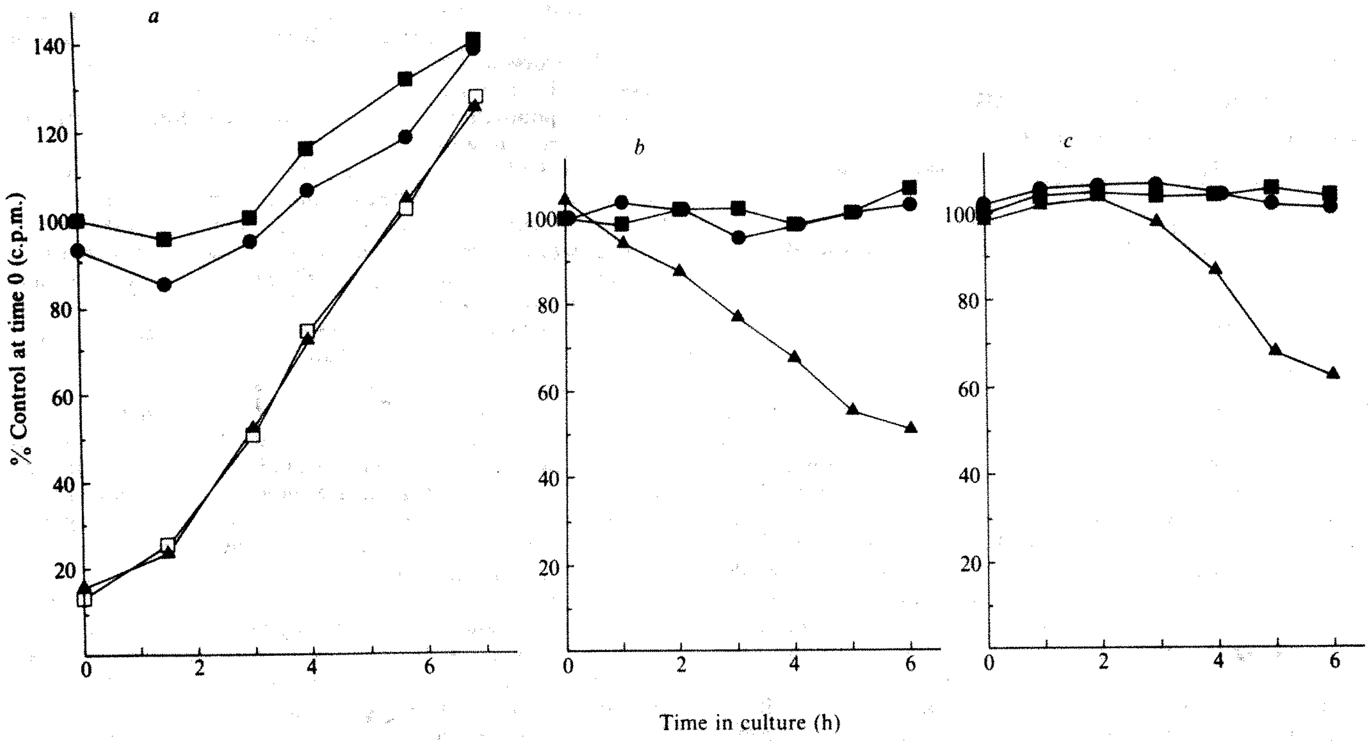

Fig. 2 Densities of surface GPLA and Ia. Ranges are omitted for clarity, but were similar to those shown in Fig. 1. *a*, Delivery of GPLA to the surface following treatments with anti-Ig and/or papain. ■, Treated with sheep normal IgG 200 μg ml^{-1}, then with papain-free buffer; ▲, treated with sheep normal IgG 200 μg ml^{-1}, then with papain 1.9 mg ml^{-1} for 30 min at 37 °C; ●, treated with anti-Ig 200 μg ml^{-1}, then with papain-free buffer; □, treated with anti-Ig, then with papain. *b*, *c*, Densities of surface GPLA and Ia following treatment with anti-Ig or cycloheximide. ■, Treated with sheep normal IgG 200 μg ml^{-1}; ●, treated with anti-Ig at 200 μg ml^{-1}; ▲, treated with sheep normal IgG, then cultured in the presence of 0.1 mM cycloheximide.

rate of disappearance of surface Ig after halting protein synthesis with cycloheximide. However, Fig. 1*b* indicates that after extensive clearing of the surface Ig by antibody at 37 °C there is no significant regeneration in subsequent culture until after about 4 h (lowermost solid line). Figure 1*b* demonstrates, moreover, that amounts of antibody insufficient to clear the surface completely by capping and pinocytosis (intermediate two solid lines) nonetheless induce a delay in delivery of new surface Ig. For about 6 h after the reaction with antibody the surface Ig continues to fall, implying that reduced delivery is not keeping pace with shedding. These rates of regeneration are in striking contrast to those shown in the same figure to occur after partial or complete clearing of the surface by papain.

Figure 1*c* shows that the action of antibody and papain sequentially yields the same slow regeneration as occurs after antibody alone. This rules out the possibility that the regeneration rate after antibody is normal but after papain spuriously high due to some stimulatory action of the enzyme. It also

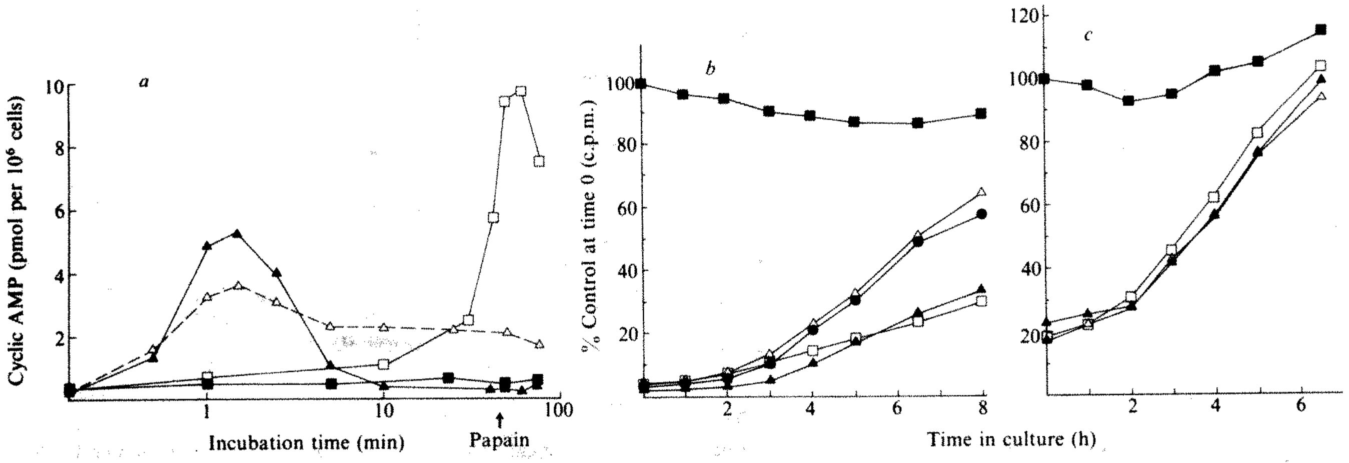

Fig. 3 Delivery of surface molecules correlated with cyclic AMP levels[14]. In *b* and *c* the ranges of triplicates were similar to those shown in Fig. 1. *a*, Levels of intracellular cyclic AMP following exposure for 45 min at 37 °C to: ■, sheep normal IgG, 200 μg ml^{-1}; ▲, anti-Ig, 200 μg ml^{-1}; △ isobutylmethylxanthine (Aldrich), 2 mM; □, cholera toxin (Sigma), 100 ng ml^{-1}. In the last three cases the cells were exposed to papain 0.1 mg ml^{-1} for 30 min at 37 °C immediately after exposure to the primary agent, so as to mimic conditions for the experiment depicted in *b*. The treatment with papain in fact made no difference to the levels of cyclic AMP attained, and viability (exclusion of Trypan blue) remained at >95% in all groups. *b*, Delivery of surface Ig after treatment for 45 min at 37° with: ▲, anti-Ig, 200 μg ml^{-1}; △, isobutylmethylxanthine, 2 mM; □, cholera toxin, 100 ng ml^{-1}. After these primary treatments the cells were treated with papain 0.1 mg ml^{-1} for 30 min at 37 °C to remove residual surface Ig, and finally washed and cultured to observe regeneration of the surface Ig. Two control groups were exposed to sheep normal IgG, 200 μg ml^{-1}, as the primary treatment: ●, followed by treatment with papain; ■, not followed by papain. *c*, Delivery of surface GPLA following treatment as in *b*, but with papain at 1.9 mg ml^{-1} to remove residual GPLA.

provides evidence against the possibility that delayed regeneration following antibody treatment is due to chronic clearance by persisting sheep antibody on the surface, because this antibody would itself have been susceptible to proteolysis by papain.

In experiments in which the cells were allowed to react with monovalent Fab′γ fragments of antibody, no effects were observed on the density of the surface Ig, whereas F(ab′γ)$_2$ fragments had the same effect as whole antibody. Thus, it seems that a necessary signal for delayed delivery is cross-linking of the surface Ig, with no apparent role for the antibody Fc region.

The experiments shown in Fig. 2 indicate that anti-Ig reacting with L$_2$C cells had no effect on the delivery of two non-Ig molecules, GPLA and Ia, to the cell surface. Figure 2*a* shows that the rate of regeneration of GPLA following its removal by papain is independent of the cell being exposed to anti-Ig. (The rising control values were often seen with this antigen, and might be related to the cell cycle[13].) A similar experiment could not be carried out for Ia, which could not be removed by any of a series of proteolytic enzymes tested. However, Fig. 2*b* and *c* show, respectively, that neither GPLA nor Ia underwent any diminution in density after the cells had been treated with anti-Ig, contrary to the result expected if delivery of these molecules were impeded. To confirm that both molecules are, in fact, turning over at the cell surface, the same graphs show their rates of fall-off when protein synthesis is halted by cycloheximide: the rates are apparently similar, but with a delay of about 2 h before the Ia starts to fall off, presumably reflecting the size of an intracellular pool.

There is some evidence of the pathway leading to suppression of Ig delivery. Previous work has shown that anti-Ig acting on the L$_2$C surface triggers a surge in cyclic AMP within the cell[14]. Protein kinases will thereby be activated, to phosphorylate other enzymes and possibly finally to yield reduced Ig delivery, among other effects. Such an interpretation is supported by the experiment shown in Fig. 3. Cholera toxin, binding to different receptors (ganglioside g_{M1}) on the surface[15], caused after a lag period a marked increase in cyclic AMP and then a reduced delivery of Ig but not of GPLA. The effect was strikingly similar to that given by anti-Ig. Another means of raising the cyclic AMP level, slowing its breakdown by the phosphodiesterase inhibitor isobutylmethylxanthine, had no detectable effect on delivery to the surface. Note, however, that the rise in cyclic AMP caused by this agent can be expected to occur throughout the cell rather than to be concentrated under the plasma membrane, a difference likely to give different sequelae[16].

Two lines of evidence suggest that antibody need only cross-link surface Ig to generate the signal which culminates in reduced Ig delivery. First, clearing by capping and pinocytosis is not necessary (Fig. 1*b*). Second, the surge in cyclic AMP is evident within 30 s (ref. 14), too short a time for any obvious interiorisation of antibody–Ig complexes[2]. Nevertheless, we cannot entirely rule out a need for at least minimal pinocytosis of the complexes.

We intend to apply the techniques used in this work to investigate other neoplastic lymphocytes, in particular, those of human chronic lymphocytic leukaemia. Clearly, caution must be exercised in extrapolating the behaviour of neoplastic cells to that of their normal counterparts. However, in the present case there is already evidence that the basic phenomenon is expressed to different degrees in normal cells[3–5,17]. Under such circumstances neoplastic cells, by virtue of their availability and homogeneity, offer considerable scope for elucidating mechanisms and perhaps for providing models of the normal stages of differentiation.

The perturbation of surface Ig in leukaemic lymphocytes by anti-Ig also has therapeutic implications. On these surface molecules there are idiotypic determinants, essentially unique to the clone of cells bearing them, and anti-Ig directed against these particular determinants may prove therapeutically useful[18].

A reference GPLA antiserum was supplied by Dr Ethan Shevach. This work has been supported by Tenovus of Cardiff, the Cancer Research Campaign and the Wessex Regional Health Authority.

Human T lymphocyte clones reactive in primed lymphocyte typing and cytotoxicity

Fritz H. Bach, Hiroo Inouye, Jacquelyn A. Hank & Barbara J. Alter

Immunobiology Research Center, and Department of Medical Genetics and Surgery, University of Wisconsin, Madison, Wisconsin 53706

The human HLA-D region, the presumed evolutionary homologue of the H-2 I region in mouse and similar genetic regions in other species[1], codes for multiple antigenic determinants, a finding consistent with the existence of multiple loci[2,3]. One method developed to define D region encoded determinants is primed LD typing (PLT) wherein cells of one individual are primed *in vitro* in a mixed leukocyte culture (MLC) to allogeneic HLA-D encoded determinants associated with one haplotype[4,5]. The PLT cells give a rapid proliferative response when restimulated in secondary culture with either the priming cells or third party cells that carry the priming antigen(s). However, as in many cases a PLT cell is probably primed to several determinants, different restimulating cells from unrelated individuals will engender a range of responses varying from very high to very low, presumably depending on the number of determinants shared (or cross-reactive) between the priming and restimulating cells. Such results are difficult to interpret in terms of defining antigenic determinants on the cells of various individuals. Fathman and Hengartner[6] have circumvented this problem in mouse by cloning murine T lymphocytes from multiply restimulated PLT cells; the progeny of any one clone give highly specific proliferative responses. We report here the use of the supernatant of phytohaemagglutinin (PHA)-stimulated mixtures of human allogeneic cells[7,8] (designated T-cell growth factor or TCGF) to grow 'clones' of human T lymphocytes following alloactivation in MLC. Clones that give PLT-type responses do so in a highly antigen-specific manner. Following cloning, cells in many cases have undergone 25 or more divisions, thus yielding in excess of 1×10^8 progeny.

All cells to be cloned were alloactivated in primary MLC and on day 4 the blast cell fraction was obtained by unit gravity sedimentation. These blast cells were either cloned, as given below, or recultured and restimulated with the sensitising alloantigens one or more times and then used 2 days after

Table 1 Proliferative response of non-cloned, PLT cells against agarose 'cloned' alloactivated cells

	Responders			
Stimulators	AB$_x$ PLT	Clone A31	Clone A17	Clone A11
HTC:				
DW1	475	NT	575	NT
DW2	708	215	711	506
DW3	478	480	696	604
DW4	281	NT	822	NT
DW5	824	NT	576	NT
DW6	1,031	368	3,031	NT
DW7	2,436	15,684	12,949	980
DW10	588	NT	674	NT
A	148	215	491	355
B	1,424	5,794	2,527	458

Ficoll-Hypaque purified peripheral blood lymphocytes from individual A (10^7) were mixed with an equal number of (4,000 rad) irradiated cells of individual B (AB$_x$) in Falcon 3013 flasks in 15% heat-inactivated human serum in RPMI-1640 with 25 mM HEPES (15% HS-RPMI). Following 1g sedimentation[12] on day 4 the 'blast' cell containing fractions were pooled and $2.5–5\times10^5$ cells in 1 ml 15% HS-RPMI mixed with 1 ml of TCGF containing agarose (Sea Plaque Agarose) to yield a predetermined, optimal concentration of TCGF and a 0.36% agarose concentration. This mixture was placed on a pre-gelled (2.5 ml) layer of 0.5% agarose in TCGF containing media in a 60-mm Petri dish, allowed to gel, and incubated in humidified 5% CO_2 in air at 37 °C until colonies of cells containing 20–100 cells appear. TCGF was always used at predetermined, optimal concentrations with 15% HS-RPMI (TCGF media) and was either prepared as described by Morgan *et al.*[7] or purchased as pooled units (Associated Biomedic Systems). Colonies were transferred after 7–14 days to round-bottom microtitre wells (Linbro 76–011–05) containing 0.15 ml of TCGF media and irradiated (4,000 rad) A or B lymphocytes as feeder cells ($5–10\times10^4$ per well). On days 5–6 of culture 50 µl of TCGF media is added to each well and after an additional 2 to 5 days of culture the amount of ^{3}H-thymidine incorporation was determined in 20-µl samples of each well. The contents of wells with dividing cells were transferred to 16×100 mm culture tubes or 16×17 mm wells (Linbro 76–033–05) containing TCGF media and $5–10\times10^5$ irradiated A or B feeder cells. Thereafter the pre-clones ('clones') were maintained at less than 10^6 cells per ml, replenished with fresh TCGF media every 2–4 days, and resupplied with feeder cells approximately every 10 days. Clones to be tested for PLT response (after washing to remove TCGF) as well as 10 day AB$_x$ PLT cells[4] were placed at a concentration of 2.5×10^4 cells per well in microtitre V-bottom plates (Linbro 76–021–05) containing 5×10^4 irradiated stimulating cells in 15% HS-RPMI and after 40 h the cultures were labelled with ^{3}H-thymidine for 8 h (A response is easily detectable at 24 h and peaks at 48 h). Values given are mean counts per minute of triplicate samples. NT, not tested.

restimulation for cloning. Cloning was attempted by two different methods. First, cells obtained from a primary MLC were placed, in the presence of TCGF, in soft agarose and 7 to 14 days later 'colonies' were removed and subsequently grown in microtitre wells in the presence of irradiated (feeder) lymphoid cells. Second, lymphocytes or cells from blast fractions from a primary MLC were placed at limiting dilutions in the wells of Terasaki microtitre plates in TCGF-containing medium also in the presence of feeder cells. One cannot be sure that the progeny obtained by either of these two methods are true 'clones' until recloning is done; although we have not, as yet, attempted re-cloning, for simplicity of expression we shall refer to the populations generated as clones.

Clones, obtained from MLC blast cells plated in agarose, were tested for reactivity to homozygous typing cells for the presently recognised HLA-DW clusters (Table 1). Of the clones that gave a proliferative response, all did so to the DW7 homozygous typing cell, as did the non-cloned AB$_x$ PLT cells which were collected and tested following the normal sensitisation time of 10 days[4,5]. In addition, some clones showed a weaker, but highly significant, response to DW6. Assuming that weak stimulation by the DW6 cells represents antigen sharing or cross-reactivity between DW7 and DW6, one would expect to find some clones that detect this 'shared' determinant; other clones should be specific for DW7. The results shown demonstrate that this is the case. In addition, these data provide evidence suggesting that HLA-D region-encoded determinants are important in the restimulation of the cloned PLT cells.

One of the 'clones' in Table 1 did not show any proliferative response to any restimulating cell tested. Cells of this clone were cytotoxically active against the original sensitising cell but not to targets autologous with the responding cells (Table 2). Agarose-cloned cells grown in TCGF are primarily T cells, 92% of which form sheep red blood cell (SRBC) rosettes while 64% of the non-cloned, AB$_x$ PLT cells (Table 1) rosette with SRBC.

Table 3 shows results obtained with cells of a number of different 'clones' obtained from a different primary MLC in terms of their PLT response either to restimulating cells from the sensitising cell donor, B, or to restimulating cells from individuals C and D, unrelated to B and the donor of the responding cells. Results obtained with the original PLT cell, AB$_x$, indicate that cells of C restimulate to a significant degree, although much less than do those of B; cells of D do not restimulate. Once again, assuming antigen sharing or cross-reactivity between B and C, one would expect to find clones, such as those represented by 40-8E and 40-4E, which give a highly significant response to restimulating cells of either B or C with still no response to cells of D. Other 'clones', such as 40-10E and 40-7E, retain specificity only for B.

Table 2 Cytotoxicity of cells from agarose clone A11 derived from alloactivated MLC blast population

	% Cytotoxicity (±s.d.) on target	
E:T	A	B
20:1	−8.4±9.3	43.1±11.0
5:1	NT	6.0±7.4
1.25:1	NT	−3.6±8.3

'Clone' A11 cells (see footnote to Table 1) were mixed at the given ratio with 1×10^4 ^{51}Cr-labelled target lymphocytes of the original responder (A) or of the original stimulator (B). After 8 h the amount of ^{51}Cr released was determined and per cent cytotoxicity calculated based on spontaneous and maximum release from the target cells in medium.

Response patterns of cells of these clones allow definition of HLA-encoded antigens with a degree of specificity previously unobtainable with the average PLT or homozygous typing cell reagent. Low levels of cross-stimulation by third party test cells of non-cloned, normal PLT reagents, a finding that has been very difficult to interpret in the past, in at least some cases apparently reflects antigen sharing or cross-reactivity. This conclusion is based on finding some clones of each PLT that are restimulated by only cells of one individual (with respect to those tested) and other clones from the same PLT that are restimulated by cells of that individual and by cells of another

Table 3 Proliferative response of non-cloned PLT versus limiting dilution 'cloned' alloactivated cells

	Restimulating cells			
Responding cells	A$_x$	B$_x$	C$_x$	D$_x$
Original PLT	173	5,152	831	207
'clones'				
40-10E	543	6,000	536	375
40-7E	641	44,681	906	489
40-8E	576	3,842	2,313	710
40-4E	814	4,634	2,475	683
40-9D	881	999	993	742

'Clones' were obtained from limiting dilution of day 4 MLC blast cells and were grown in Terasaki microtitre wells in the presence of feeder layers and TCGF. The cells were derived from wells which received on average 40 cells per well at the time of dilution into Terasaki plates. 40-9D is an example of a clone giving no proliferative response.

individual. As both HLA-D and DR antigens can restimulate PLT cells[9,10] it is most likely that cloning will allow fine structure dissection and analysis of the complex of HLA-D region-encoded antigens. PLT responses can be obtained with as few as 5×10^3 responding cells (ref. 11 and unpublished data); thus, cloning makes reagents available that could be used to type more than 1×10^4 individuals per clone. Although our emphasis has been on the testing of PLT reactive clones, the fact that cytotoxic T lymphocyte clones can also be obtained in these conditions, now makes possible certain experiments in man for the study of T lymphocyte function using homogeneous cell populations.

We thank Dr Gary Fathman for discussions, Lynn Guy for technical assistance, Cindy Smith and Michelle Howard for help in manuscript preparation and Dr Peter Wernet and the histocompatibility laboratories of the Universities of Wisconsin and Minnesota for the homozygous typing cells. Epidermal growth factor receptors increase during the differentiation of embryonal carcinoma cells

A. R. Rees,* E. D. Adamson† & C. F. Graham†

*Laboratory of Molecular Biophysics and †Department of Zoology, University of Oxford, South Parks Road, Oxford, UK

Mouse teratocarcinoma stem cells (embryonal carcinoma, or EC cells) bind very small amounts of mouse epidermal growth factor (EGF) and the latter hormone seems to have no stimulatory effect on the growth of two cloned lines of EC cells. However, when EC cells are induced to differentiate into large flat endodern-like cells (END cells), EGF receptors increase in number reaching a plateau in 6 to 8 days. At 8 to 10 days after induction, END cells multiply very slowly, but when EGF is added (3×10^{-10} M) to the medium, cell division is stimulated and a further change in morphology occurs. This letter describes the binding characteristics and numbers of the EGF receptors on EC and END cells and shows that exogenous retinoic acid increases the numbers of EGF receptors on END cells. We were unable to find endogenous competing factors produced by EC cells. Such factors could account for the lack of detectable binding of EGF on these cells. As EC cells differentiate to END cells, so the ability of the cells to form tumours is reduced[1,2]. Since this change is accompanied by an increase in the number of EGF receptors there may be a relationship between these two events.

The experiments were performed on the cloned cell lines PC13 clone 5 (ref. 3) and OC15S1 (ref. 4) which were both derived from the transplantable 129/JSv strain teratocarcinoma OTT6050 (ref. 5). Both clones are pluripotential; OC15S1 differentiates in culture to form muscle and nerve which express biochemical markers characteristic of these cell types[6,7], while

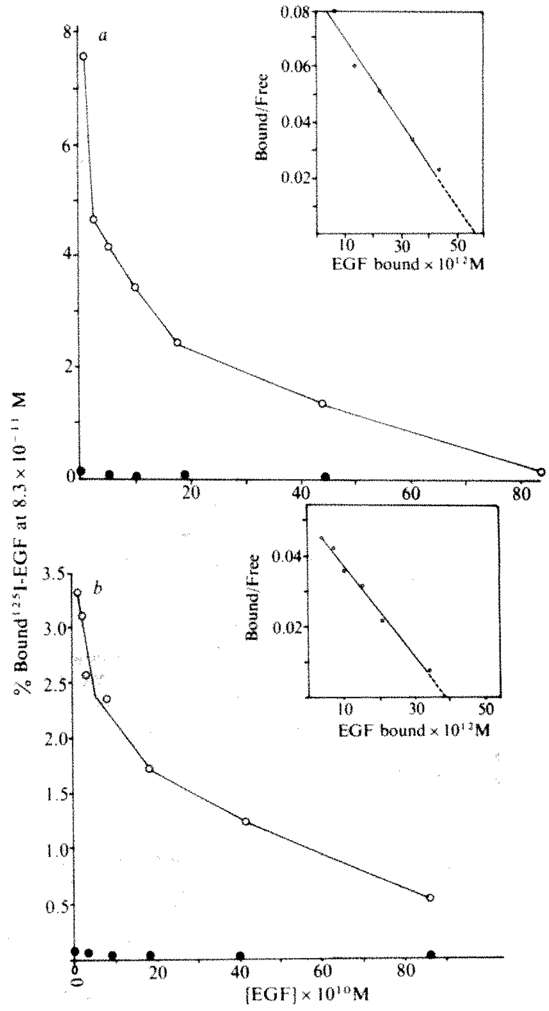

Fig. 1 Binding of ^{125}I-EGF to monolayers derived from *a*, PC13 clone 5 and *b*, OC15S1. EC cells were plated at 1×10^5 cells per 50-mm gelatinised dish in modified α-medium containing 10% fetal calf serum and 3×10^{-6} M retinoic acid[10]. Over 7 days with one change of medium, 1×10^6 END cells formed. Duplicate dishes at each point were used in binding assays. OC15 END cells were formed both as above and by the low-density plating method which does not require retinoic acid[9,10]. ^{125}I-EGF was prepared according to the following protocol: 4 μg EGF in 4 μl 0.3 M sodium phosphate buffer at *p*H 7.5 was added to 10 μl Na^{125}I (Radiochemical Centre, 100 mCi ml^{-1}). Chloramine-T 5 μl (2.5 mg ml^{-1} in water) was then added and the mixture agitated for 35–40 s after which 5 μl sodium metabisulphite (5 mg ml^{-1} in 0.3 M sodium phosphate buffer) and 100 μl bovine serum albumin (25 mg ml^{-1} in phosphate buffer) were added in quick succession. The ^{125}I-EGF was purified on a column (60 cm by 1.2 cm diameter) of Sephadex G-50 in phosphate-buffered saline containing bovine serum albumin at 1 mg ml^{-1}. Three peaks were obtained: the first contained damaged and over-iodinated material and the last free iodine. The middle peak (^{125}I-EGF) was split into 50-μl aliquots and frozen at −20 °C. The binding assay buffer contained Earle's balanced salt solution, HEPES (5 mM), and bovine serum albumin (1 mg ml^{-1}). Cell monolayers were washed twice with 2 ml buffer and then reacted with ^{125}I-EGF, finally 8.3×10^{-11} M, (970 Ci mmol^{-1} 250,000 c.p.m.) and with varying amounts of unlabelled EGF (from zero to 4×10^{-8} M) in a final volume of 2 ml buffer. The dishes were incubated at room temperature (~22 °C) for 90 min with intermittent shaking. The mixture was aspirated and the dishes were washed three times with ice-cold binding buffer. Cells were removed with 0.5 M NaOH and counted in a Hewlett–Packard γ-counter. The data points shown are the means of at least three separate determinations and values are normalised to 10^6 cells. Nonspecific binding was determined by measuring the bound counts in the presence of a large excess (520-fold over ^{125}I-EGF) of unlabelled EGF and was generally less than 5% of the specifically bound counts. ●, EC cells; ○, END cells. Inserts, Scatchard plots used to calculate binding constants.

0028–0836/79/390309—03$01.00

Table 1 Comparison of binding of ^{125}I-labelled EGF to various cell lines

Cell type	Additions	% EGF bound at 10^{-10} M per 10^6 cells	% EGF bound relative to PC13 END
PC13 EC	None	<0.1	<1.4
PC13 END	RA (1 d)	1.3	17.6
	RA (2 d)	3.2	43.2
	RA (5 d)	4.9	66.2
	RA (6 d)	7.2	97.3
	RA (8 d)	7.4	100.0
OC15 EC	None	<0.05	0.7
OC15 EC	RA (1 d)	0.15	2.0
OC15 END	None (7 d)	1.08	14.5
OC15 END	RA* (7 d)	3.31	44.7
PSA5E	None	1.3	17.6
PSA5E	RA (2 d)	1.25	16.9
PYS-2	None	<0.1	<1.4
PYS-2	RA (2, 4, 6 d)	<0.1	<1.4

The conditions for binding were as detailed in Fig. 1 legend. When retinoic acid was used it was added at 3×10^{-3} M in dimethyl sulphoxide (DMSO) to a final concentration of 3×10^{-6} M. As far as possible, cell densities were maintained at 10^6 cells per 50-mm dish. Separate experiments showed that the amount of ^{125}I-EGF bound increased linearly with cell density and that there was no decrease in binding as confluency was approached. The possibility that retinoic acid competed with ^{125}I-EGF for receptor sites was eliminated in separate control experiments. Addition of DMSO alone to EC cells affected neither the morphology of the cells nor the amount of ^{125}I-EGF bound.

* Retinoic acid was removed for 24 h before the assay.

PC13 forms these and other cell types when injected into adult hosts[8]. Both clones form large flat cells when grown in retinoic acid (3×10^{-6} M); and similar END cells are formed when OC15S1 cells are plated at low density and grown in a minimal medium[9,10]. Retinoic acid has been shown previously to induce EC cells to develop into endoderm-like cells which secrete plasminogen activator[11,12], type I-like collagen[10] and basement membrane protein[13].

EGF is a potent polypeptide mitogen extracted from mouse submaxillary glands (EGF, Collaborative Research). It interacts with specific cell-surface receptors on mouse and human fibroblasts, glial cells and corneal epithelial cells[14,15]. When mature END cells were incubated with ^{125}I-labelled EGF at 8.3×10^{-11} M in the presence of increasing concentrations of unlabelled EGF, specifically bound EGF was detected (Fig. 1). The data shown in Fig. 1 were used to estimate the binding association constants (K_a) and the numbers of EGF receptors per cell by Scatchard plots[16]. The value of 1.4×10^9 M^{-1} and 1.2×10^9 M^{-1} for PC13 END and OC15 END respectively are close to the K_a of 2.3×10^9 M^{-1} for human foreskin fibroblasts obtained by Carpenter and Cohen[1]. The latter cells have 10^5 EGF receptors per cell whereas END cells have slightly fewer: 7×10^4 for PC13 END and 3.1×10^4 for OC15 END. The number of EGF receptors in a mouse fibroblast line (STO[17]) was found to be similar to that in human fibroblasts; STO was therefore used as a positive control in these experiments.

The formation of PC13 END from EC cells takes place gradually on exposure to $3-6\times10^{-6}$ M retinoic acid, and the original small round EC cells form extremely large and flat cells (Fig. 2*a*, *b*, *c*). During the development of END cells there is some cell death[1] and this raises the possibility that during the formation of END cells, a minor subpopulation of EC cells with EGF receptors survives and overgrows during the END cell transition. However, this phenomenon is unlikely to explain our results with PC13 END cells because 24 h after the addition of retinoic acid, cell numbers had less than doubled while the amount of EGF bound had increased 12-fold. Table 1 shows that there is a gradual increase in the amount of EGF bound per cell during the transition; this is probably due to the gradual formation and maturation of END cells. PC13 EC and OC15S1 EC cells bound very little ^{125}I-EGF. It is clear from Table 1 that OC15 END cells which were formed in the presence of retinoic acid were able to bind higher levels of ^{125}I-EGF than similar END cells formed in the absence of exogenous retinoic acid. We also tested two teratocarcinoma-derived differentiated cell lines which were known to have endoderm-like properties. PSA5E cells[18] bound ^{125}I-EGF and binding was unchanged by the addition of retinoic acid; PYS-2 cells[19] did not bind significant amounts either in the presence or absence of retinoic acid. These cell lines are thought to possess endoderm properties similar to those of visceral yolk sac endoderm and parietal endoderm, respectively. This finding raised the possibility of differential distributions of EGF receptors in embryos and preliminary studies confirm this (manuscript in preparation).

Retinoic acid is required for the transition of PC13 EC into END cells, and promotes the formation of larger numbers of EGF receptors on OC15 END (Table 1). In contrast, a third effect occurs on removal of retinoic acid from PC13 (and OC15) END cells for various times before applying the ^{125}I-EGF binding assay. The number of EGF receptors on PC13 END cells was found to have increased to 28% above normal after 2 days culture in the absence of retinoic acid. Opposing effects of retinoic acid have also been documented in respect of its ability both to enhance tumour growth and to oppose promoters of tumour growth (see ref. 20 for review).

Figure 3 shows the effect of EGF on the growth of PC13 END cultured in 50-mm dishes seeded at 1×10^5 cells per dish. In one series EGF was absent and the cell number either decreased or remained the same; this depended on the age of the cells and the density of seeding but the continued presence of retinoic acid had no effect. In the other series, the addition of EGF at 2 ng ml^{-1} caused cell numbers to increase three- to fourfold in 6 days. The continued presence of retinoic acid appeared to be necessary to maintain this rate of cell division. OC15SI END cells responded similarly to EGF (not shown). After about 2

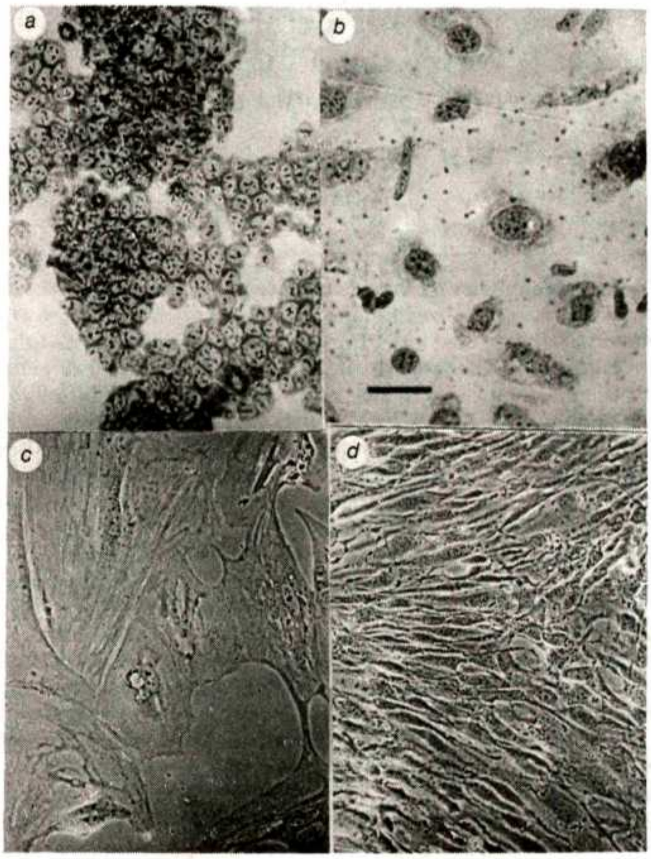

Fig. 2 Photomicrographs of; *a* EC cells; *b*, END cells stained with Giemsa; *c*, END cells; *d*, END cells after 4 days growth in EGF (3.7×10^{-10} M), phase contrast. All at the same magnification, scale bar, 50 μm.

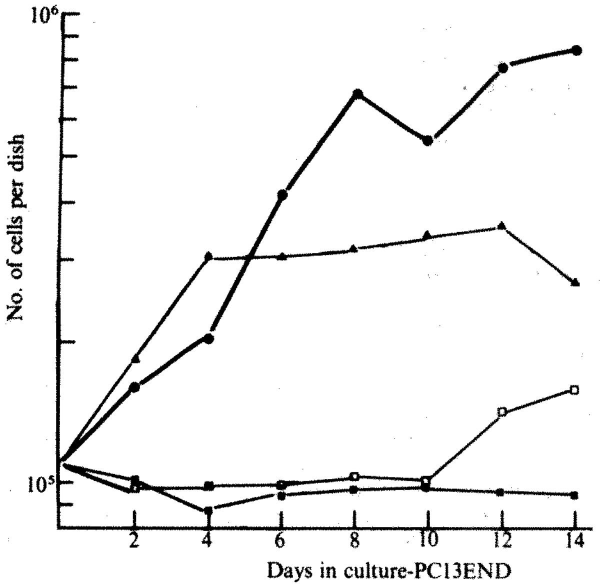

Fig. 3 Growth curves of PC13 END cells. END cells were formed as described in Fig. 1 legend and then reseeded at about 1×10^5 cells per 50-mm dish and cultured for two more days in medium containing 3×10^{-6} M retinoic acid. Medium was replaced with one containing 3.7×10^{-10} M EGF (▲); 3.7×10^{-10} M EGF and 3×10^{-6} M retinoic acid (●); with retinoic acid (■); or with neither (□). Cells in duplicate dishes were counted every other day and the medium was changed every 3 days. Similar results were obtained in each of three experiments with PC13 END and twice for OC15 END cells.

days in contact with EGF, PC13 END cells changed to a fibroblastic appearance (Fig. 2*d*) and later when more dense, they formed multilayers.

In a similar experiment the effect of EGF on the growth of OC15S1 and PC13 EC cells was tested (not shown). No effect was detected on the already fast multiplication rate of these cells (approximate doubling time 17 h). This finding was in accord with the very low binding of ^{125}I-EGF to EC cells shown in Table 1. It was possible that EGF receptors were present on EC cells but were masked by endogenous growth factors. Such factors have been described[21]: they were secreted by Moloney sarcoma virus (MSV)-transformed mouse cells; they had a mitogenic action on rat fibroblasts; and they competed with ^{125}I-EGF in the EGF receptor-binding assay. We have been unable to find any endogenous growth factors secreted into the medium or in the cytosol of PC13EC cells, but END cells shed a material which may contain EGF receptors since it inhibited the binding of ^{125}I-EGF to PC13 END cells by nearly 90%. During the incubation, END cells remained healthy and cell breakdown could not account for any release of proteases which might have affected the binding assay. It is also known that human lymphocytes shed insulin receptors when cultured in serum-free medium[22].

The main finding of these experiments is that both PC13 and OC15S1 EC cells, when allowed to transit into END cells, develop EGF receptors while also changing in morphology and in macromolecular secretory products[1]. We believe that the transition is a differentiative process and that an endoderm-like cell is the product[10-13]. END cells have a very low incidence of tumour formation: in contrast, EC cells are highly tumorigenic in adult hosts and therefore lack the growth controls which operate on normal cells. Hence the very low numbers of EGF receptors on EC cells and the very large numbers on END cells may indicate that EGF receptors are part of the growth control of these cells. Cells which are transformed by MSV[23] or by phorbol esters[24], have a decreased number of available EGF receptors (or reduced-affinity receptors[25]) and transformation can be blocked by retinoids[26]. It is possible that the blocking effect of retinoids is mediated through the renewed operation of EGF and the EGF-receptor system, since we show here that retinoic acid stimulates the production of EGF receptors. The experiments reported above demonstrate an increase in the numbers of EGF receptors with differentiation and the results are consistent with the hypothesis that teratocarcinoma tumour stem cells (and early embryonic ectoderm therefore) only become subject to growth control by EGF after their differentiation into cells of a more specialised and restricted type. It should be possible to test this hypothesis further.

This investigation was supported by grants from the MRC. We thank S. Gaunt for providing the PC13 clone 5 line.

Sequential X chromosome inactivation coupled with cellular differentiation in early mouse embryos

Marilyn Monk & Mary I. Harper

MRC Mammalian Development Unit, Wolfson House,
4 Stephenson Way, London NW1, UK

Only one of the two X chromosomes is active in each somatic cell of adult female eutherian mammals, making the females (XX) equivalent to the males (XY) with respect to X chromosome dosage[1-4]. Biochemical analyses showing that both X chromosomes are active in female mouse embryos in mid-cleavage stage[4-8] indicate that X chromosome differentiation involves inactivation. This event occurs in most or all cells of the embryo at the blastocyst stage[4,7-9], when there are two cell types, the outer sphere of trophectoderm cells and the inner cell mass (ICM). Because there is genetic evidence that both X chromosomes are potentially active in ICM cells[10], it has been suggested that X chromosome inactivation has occurred in only the trophectoderm cells[9]. Further, one of us (M.M.)[4] has proposed that X chromosome differentiation is linked to cellular differentiation, occurring at different times in different cell populations as they 'depart' or terminally differentiate from a pluripotent fetal 'stem line' (Fig. 1). Analysis of a large number of inner cell masses isolated immunosurgically from female blastocysts has yielded data consistent with the presence of two active X chromosomes[11], but ICMs are so small that the biochemical assay used was at the limit of its accuracy. (Neverthe-

0028-0836/79/390311—03$01.00

less, a computer analysis of the data[8] indicated two ICM populations differing twofold with respect to X chromosome activity.) More tissue is available for analysis in post-implantation embryos, in which, on the above hypothesis, we would expect two active X chromosomes in the pluripotent epiblast region before gastrulation, but only one in the corresponding extra-embryonic ectoderm (a trophectoderm-derived tissue[12]) and primary endoderm (ICM-derived[12], see Fig. 1). We report here that this is the case; we also show that inactivation is complete in the epiblast (fetal precursor) cells between 6.0 and 6.5 d of gestation at the onset of gastrulation.

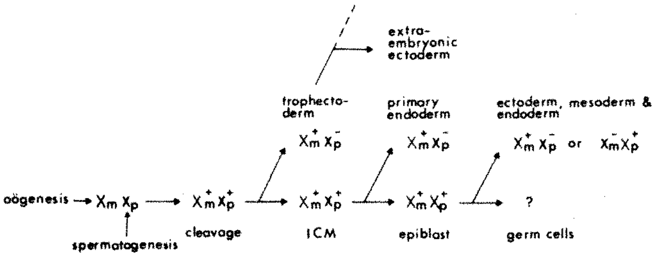

Fig. 1 Hypothesis linking X chromosome differentiation to cellular differentiation[4]. X chromosome differentiation is shown as occurring in different cell lineages as they differentiate (m, maternal; p, paternal; +, active; −, inactive). Tissues differentiating early, that is, trophectoderm and primary endoderm, show preferential inactivation of the paternally inherited X chromosome[16–18], suggesting some memory mechanism[2] detecting the parental origin of the two X chromosomes. This memory mechanism is presumably lost by the time of gastrulation when inactivation is random.

We used a biochemical assay to measure simultaneously the activities of two enzymes in dissected tissues of individual post-implantation embryos. These enzymes are the X-coded hypoxanthine phosphoribosyl transferase (HPRT, EC 2.4.2.8) and the autosomally coded[13] adenine phosphoribosyl transferase (APRT, EC 2.4.2.7). The assay has been previously described[6] (see Fig. 2 legend) and its validity recently unequivocally confirmed by thin layer chromatography (M.I.H. and M.M., unpublished). The results are expressed as a ratio of HPRT to APRT activities for a particular dissected tissue from an individual conceptus, thus eliminating sampling errors which would be introduced by variation in the amount of pure dissected tissues recovered. We expect the ratio of X-coded HPRT to autosomally coded APRT activity to be twice as high in an XX tissue as in an XY tissue if both X chromosomes are active in that particular region of the female conceptus.

Swiss female mice (MF1, Olac UK) were mated between 1100 and 1700 h to MF1 males in a reversed day/night room. The embryos were isolated from the uteri of these females 6 days later (6-d conceptuses), the trophectoderm and ectoplacental cone discarded and the egg cylinders dissected into three tissue populations: epiblast, extra-embryonic ectoderm and primary endoderm (see Fig. 2*a*). Extracts of these tissues were assayed for HPRT and APRT activity, and the ratios of activities of these enzymes per tissue per embryo are given in Fig. 2. It can be seen that whereas the values for the extra-embryonic ectoderm and primary endoderm regions (Fig. 2*c*, *d*) show unimodal distributions with a less than twofold spread, the values for the epiblast region (Fig. 2*b*) are bimodal. A computer analysis indicated two populations of epiblasts in the proportion 0.6 : 0.4 (lower : higher) and gave estimates compatible with a twofold difference between the means. By analogy with previous work[4,6,11], we assume that the bimodality is due to a bimodal distribution of X-coded HPRT activities. The results shown in Fig. 2 suggest that X chromosome inactivation has already occurred in extra-embryonic ectoderm and primary endoderm, whereas there seem to be two populations with respect to X chromosome activity in epiblast regions.

Several of these epiblasts were sexed by karyotyping their respective extra-embryonic regions. The results are shown in Fig. 3. The mean of HPRT/APRT ratios for the female epiblasts is significantly higher than that for male epiblasts (Student's *t*-test gives $t_{24} = 3.14$, $P < 0.01$). The fact that more epiblasts in Fig. 2 are located in the lower peak (see above) is consistent with the overlap between male and female values indicated in Fig. 3, and suggests that X chromosome inactivation has already occurred in about one-fifth of the XX epiblasts. One possible explanation for the bimodality in the epiblasts is that X chromosome inactivation has occurred at the same time as in primary endoderm, but that HPRT activity observed in 6-d epiblasts is due to enzyme which was present in the cells before this event. We consider this explanation unlikely because the 6-d epiblast is the most rapidly proliferating region of the embryo[14]. We do not know the spread in timing of the inactivation event in individual epiblast cells, but we can conclude that it occurs at around 6 days' gestation.

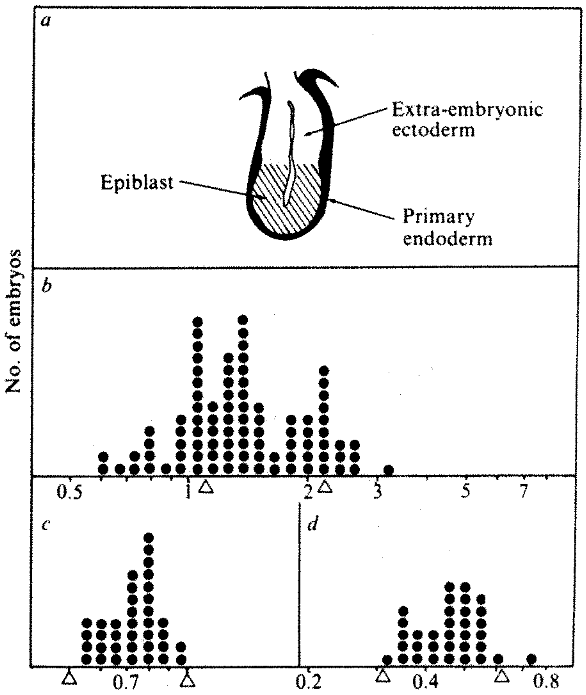

Fig. 2 Ratios of HPRT to APRT activities in dissected tissues of 6-d egg cylinders. *a*, Diagrammatic representation of 6-d egg cylinder; *b*, HPRT : APRT in individual epiblasts; *c*, HPRT : APRT in individual extra-embryonic ectoderm regions; *d*, HPRT : APRT in individual primary endoderm regions. The egg cylinders were isolated from decidua, washed in PB1 medium[24] containing 0.4% polyvinylpyrrolidone instead of albumin, and transferred to PB1 containing 0.5% trypsin and 2.5% pancreatin for 10 min at 4 °C. Enzyme treatment was terminated by the addition of fetal calf serum (to 2%). The egg cylinders were washed in PB1, the three components of each separated using finely drawn Pasteur pipettes and glass needles and transferred separately in 5 μl of medium to 10-μl microcaps. The microcaps were sealed and freeze-thawed three times in liquid nitrogen to lyse the cells. After centrifugation, the supernatants were transferred to 50 μl of reaction mix containing sodium phosphate buffer (35 mM, *p*H 7.4), magnesium chloride (5 mM), phosphoribosyl pyrophosphate (2 mM), ^{3}H-guanine sulphate (10 μM, specific activity 610 Ci mol^{-1}) and ^{14}C-adenine (10 μM, specific activity 286 Ci mol^{-1}). Reactions were carried out at 37 °C for 2 h. Further details are given in ref. 6. Arrowheads indicate a twofold span on the horizontal axis (logarithmic) for each distribution.

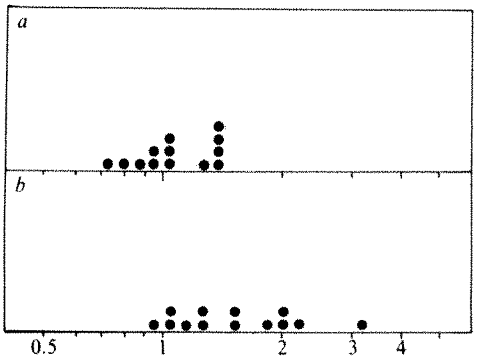

Fig. 3 Ratio of HPRT to APRT activities on 6-d male (*a*) and female (*b*) epiblasts. Embryo isolation and dissection, and enzyme assays were carried out as described in Fig. 2 legend. Individual extra-embryonic ectoderms were karyotyped as follows: tissues were incubated individually in droplets of Dulbecco's modified Eagle's medium (DMEM) containing 5% fetal calf serum and incubated overnight at 37 °C in a 5% CO_2-in-air atmosphere. They were transferred to the same medium containing 0.1 μg ml^{-1} colcemid and incubated for 4 h, followed by transfer to 1% sodium citrate for 45 min at room temperature, then to fresh fixative (3 : 1 ethanol/glacial acetic acid) at 4 °C for a minimum of 30 min. Spreads were made by transferring the tissue in a microdrop of fixative to a clean slide, promptly adding two droplets of 60% acetic acid and spreading on a hot plate at 60 °C. The preparations were stained in Giemsa diluted 1 : 10 in a phosphate buffer, *p*H 6.9, for 10 min. Sex determination was based on the presence of two versus three small chromosomes.

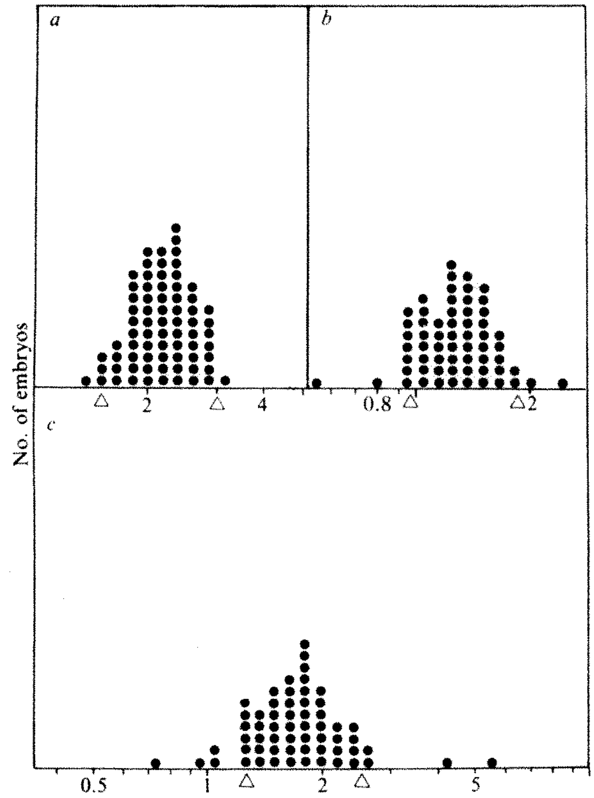

Fig. 4 Ratios of HPRT to APRT activities in dissected tissues of 6½-d egg cylinders. *a*, HPRT : APRT in individual epiblasts; *b*, HPRT : APRT in individual extra-embryonic ectoderm regions; *c*, HPRT : APRT in epiblast/HPRT : APRT in extra-embryonic ectoderm, per individual egg cylinder. Embryo isolation and dissection, and enzyme assays were carried out as described in Fig. 2 legend.

Twelve hours later in development there is no difference between the distributions of HPRT/APRT ratios in epiblasts and the other tissues (Fig. 4). Here, dissected epiblast and extra-embryonic ectoderm regions of 6½-d conceptuses (6½ d following mating in a normal day/night mouse room) show similar unimodal distributions which are incompatible with two populations with twofold differences in X-coded HPRT activity. The ratios of the HPRT/APRT values in epiblast to those of the corresponding extra-embryonic ectoderm are also convincingly unimodal (Fig. 4*c*). We conclude that X chromosome inactivation has occurred in epiblast regions by 6½ days' gestation. Kozak and Quinn[15] analysed individual post-implantation embryos for the X-coded phosphoglycerate kinase (PGK, EC 5.3.1.1). They failed to detect a bimodal distribution of (presumably) whole egg cylinders (epiblast + extra-embryonic ectoderm + endoderm), but the embryos they analysed seem to have been more closely equivalent to our 6½-d embryos.

Our findings provide strong evidence for the hypothesis outlined in Fig. 1 that X chromosome differentiation in early development is linked to cellular differentiation. The activity status of the X chromosomes in the germ cell line is not clear. It is of interest that tissues arising from trophectoderm and primary endoderm isolated from later post-implantation stages show preferential inactivity of the paternally inherited X chromosome[16–18]. Cells differentiating early in development seem to have some memory mechanism which recognises the origins of the two X chromosomes.

The coupling of X chromosome differentiation with cellular differentiation may mean that the mechanisms involved in 'switching-off' the whole X chromosome are similar to those which select activity or inactivity in different autosomal regions characteristic of specialised cell function. Ohno[19] has suggested that similar basic mechanisms might be expected for X-inactivation and cellular differentiation. However, attempts to examine X-inactivation by reversing the process have yielded little information; apart from localised derepression[20], strong selective pressures have failed to reverse the inactive state of the silent X chromosome[21,22]. Martin *et al.*[23] have shown that X chromosome inactivation occurs with *in vitro* differentiation of an XX teratocarcinoma cell line. One of the implications of their findings, and ours, is that two active X chromosomes may be incompatible with the differentiated state.

We thank Hugh Paterson for help with the embryo dissections shown in Fig. 4, Anne McLaren for verifying the karyotypes of the samples in Fig. 3 and for her critical reading of the manuscript, and R. Cuthbertson for computer analysis of the data.

Zoological origin of gonadotropin subunits and association kinetics

Jacques Marchelidon*, Roland Salesse†, Jean Garnier†, Elisabeth Burzawa-Gerard* & Yves-Alain Fontaine*

† Laboratoire de Biochimie physique, INRA, Service de Biologie physico-chimique, Bât. 433, Université de Paris-Sud, 91405 Orsay, France.

Mammalian luteinising hormone (LH) is an association of two dissimilar subunits, α and β. *In vitro* studies, mainly using difference spectrophotometry, had shown that this phenomenon was slow, especially at low temperatures. If the situation was the same in poikilotherms, it would probably make gonadotropin (GTH) synthesis difficult for these animals in a cold environment. We have found that the formation of a teleost gonadotropin is in fact strikingly more rapid and less thermodependent than formation of mammalian LH. Also, studies with a fish–mammal hybrid molecule have allowed us to estimate the respective influence of the α and β subunits in determining these differences.

Association of mammalian LH subunits is a very slow process. Various methods of study have given convergent results indicating that maximal association is not attained before several hours at 37 °C, or several days at 20 °C[1-3]. Indeed the phenomenon is highly thermodependent[3,4]; at 0 °C no significant association was observed after 6 hours[3].

It became possible to investigate this problem in a poikilotherm when α and β subunits of GTH from a teleost fish, the carp (*Cyprinus carpio L.*) were isolated, and shown to reassociate[5]. Carp GTH(c-GTH) and its subunits were prepared according to Burzawa-Gerard[5] and dissolved in 0.02 M phosphate buffer *p*H 7.4 containing 0.1 M KCl. Carp GTH α and β were mixed in equimolar amounts assuming respective molecular weights of 14,000 and 17,000[6]. Subunit association was followed by difference spectrophotometry in conditions as used previously for the study of ovine LH (o-LH) formation[2,7] at three concentrations of each subunit (1.9, 3.6 and 6.8 μM, recalculated from absorbance at 280 nm). At 20 °C and for a concentration of 6.8 μM, the percentage association was 75% after only 45 min of incubation and was still clearly increasing at this time[8]. This indicated that virtually all the subunits were able to associate, and this was confirmed by bioassay; indeed a 60–100% recovery of biological activity (measured by the frog spermiation test) was obtained, depending on the conditions of incubation[9].

Figure 1 shows the results obtained at 4 °C. When the inverse of the concentration in free subunits was plotted as a function of time, parallel straight lines were obtained with the three different initial concentrations of subunits, indicating an apparent second order reaction with a rate constant (k) equal to $78 \pm 9\ \mathrm{M}^{-1}\ \mathrm{s}^{-1}$. Confirming this, a first order plot was nonlinear with estimated rate constants depending on subunit concentration. At 20 °C, the results (not shown) were qualitatively similar to those at 4 °C but k was $149 \pm 24\ \mathrm{M}^{-1}\ \mathrm{s}^{-1}$. Between 4 and 20 °C the Q_{10} of the reaction was 1.5 (limits for $P = 0.05$: 1.44–1.57). These values are strikingly different from those measured for o-LH (k 20 °C $= 0.86\ \mathrm{M}^{-1}\ \mathrm{s}^{-1}$; $Q_{10} = 4.8$ between 10 and 37 °C)[4]. Indeed, even at the low temperatures at which fish tend to live, the formation of GTH from its subunits may occur at a reasonable rate. Note that the changes in the circular dichroism spectrum seen during hormone formation from subunits are very similar for c-GTH and for o-LH[7]. As for mammalian hormones, thermal perturbation spectroscopy of c-GTH showed that three tyrosine residues (3.2 ± 0.2) were shielded from the solvent when the subunits were associated. These data show that similar structural changes occur during the formation of c-GTH or mammalian LH from their subunits, although these associations proceed at markedly different rates.

Table 1 Thermodynamic parameters for the formation of c-GTH, hybrid b-LH α–c-GTH β, and o-LH from subunit components at 20 °C

	Enthalpy (ΔH^*, kcal M^{-1})	Entropy (ΔS^*, cal $\mathrm{K}^{-1}\ \mathrm{M}^{-1}$)	Free enthalpy (ΔG^*, kcal M^{-1})
c-GTH	+5.38	−30.1	+14.2
Hybrid	+6.62	−31.3	+15.80
o-LH†	+23.5	+21.5	+17.2

The thermodynamic parameters were calculated by plotting ln k against $1/T$ (T, temperature in K). Measuring the slope of the curve ($-(E/R)$, where E is the energy of activation) we obtained $\Delta H^* = E - RT$, then $\Delta G^* = RT(\ln KT/h - \ln k)$ and $\Delta S^* = \Delta H^* - \Delta G^*/T$ (K, Boltzmann constant; h, Planck constant).

† Data calculated from ref. 4.

An attempt was made to determine the respective roles of α and β subunits in the important differences observed between the formation kinetics of c-GTH and o-LH. To this end, we took advantage of the fact that bovine (b)-LH α and c-GTH β are able to associate and to form a hybrid molecule possessing a very high biological activity on frog spermiation[10]. Bovine LH α and c-GTH β were mixed in equimolar amounts and the association process was followed by difference spectrophotometry at two concentrations (3.3 and 6.3 μM) and two temperatures (4 and 20 °C (Fig. 2)).

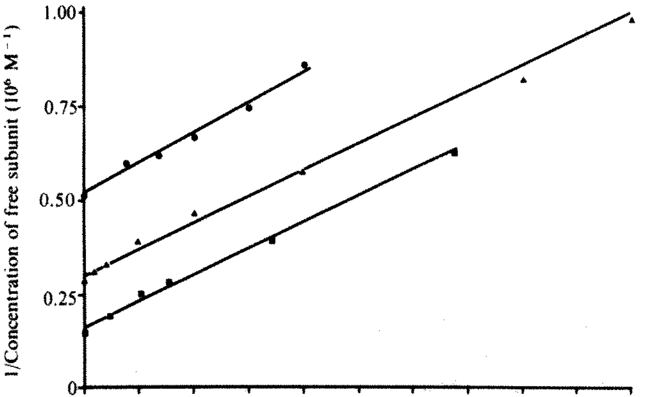

Fig. 1 Second order rate plot of the association of c-GTH subunits at 4 °C. Equal volumes (680 μl) of α or β subunits solutions were placed into the compartments of a double-sector cell. Two such cells were prepared. After equilibration of the temperature (zero time) mixing was accomplished in one of them (sample cell), the other, unmixed, cell being used as reference. The difference in absorbance at 287 nm was scanned at various times on a Cary 118 spectrophotometer. Separately, the maximum absorbance difference (ΔA_{max}) corresponding to a 100% unfolding of c-GTH was measured between two solutions of native hormone at the same concentration (8.6 μM), one of which was acidified at *p*H 2.0 with 5 M HCl (complete unfolding of c-GTH); the ratio of ΔA_{max} to the A_{280} of the native hormone solution was 0.11. The percentage of association at each time was then calculated as the ratio: ΔA_{287} between mixed and unmixed cells/$0.11 \times A_{280}$ of the native hormone solution at the concentration under study. The concentration of free, native subunits was determined from this percentage by assuming that all the subunits present at zero time were able to associate (see text). The inverse of the free subunit concentration was plotted as a function of time. Experiments were carried out at three subunit concentrations: 1.9 μM (●), 3.6 μM (▲) and 6.9 μM (■). The correlation coefficient was >0.99 in each case.

0028-0836/79/390314—02$01.00

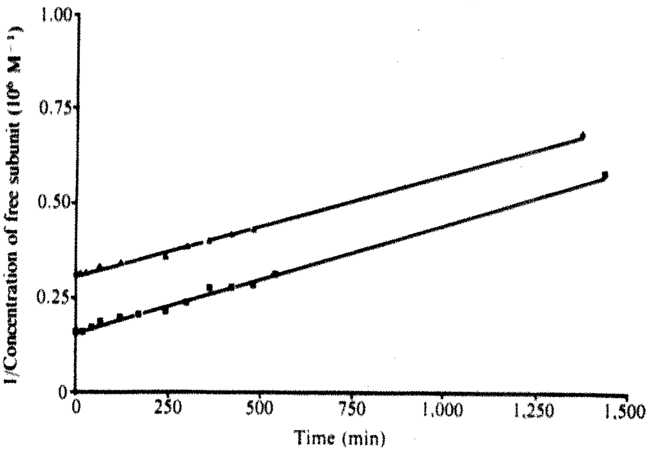

Fig. 2 Second order rate plot of the formation of hybrid b-LH α–c-GTH β from subunits at 4 °C. Association was followed as described in Fig. 1. The maximum absorbance difference corresponding to a 100% unfolding was measured between two solutions of purified hybrid at 6.2 μM, one of which being acidified at *p*H 2.0 with HCl 5 N; the ratio of ΔA_{max} to A_{280} of the hybrid solution was 0.094. Purified hybrid was obtained as follows; a mixture of b-LH α and c-GTH β (124 μM each) was incubated for 16 h at 20 °C, gel-filtered on Sephadex G-100 in NH_4HCO_3 0.1 M; the fractions with an exclusion coefficient from 0.1 to 0.32, corresponding to a protein peak with a molecular weight close to 30,000, were pooled and lyophilised. Calculations were carried out as indicated in Fig. 1 legend. The inverse of the free subunit concentration was plotted as a function of time. Association kinetics were studied at two subunit concentrations: 3.3 μM (▲) and 6.3 μM (■). The correlation coefficient was >0.99 in each case.

At 20 °C and for a concentration of 6.3 μM, the percentage of association was about 80% after 900 min and it was still clearly increasing at this time. Bioassays confirmed that virtually all the b-LH α and c-GTH β molecules were able to associate: a mixture of these two subunits (62 μM each) was incubated for 6 h at 25 °C; then the dose inducing 50% positive responses (D50) in the frog spermiation test was 0.15 μg (0.09–0.25) not different from the D50 for purified hybrid prepared as described in the Fig. 2 legend.

As for c-GTH subunits, the kinetics of association of b-LH α and c-GTH β indicated an apparent second order rate reaction at both 4 °C (Fig. 2) and 20 °C (data not shown). The *k* values were 4.8 $M^{-1}\,s^{-1}$ (5.0–4.6) at 4 °C and 9.8 $M^{-1}\,s^{-1}$ (9.7–9.9) at 20 °C; the Q_{10} within this interval was 1.5.

Thermodynamic parameters for the association reaction were calculated and are presented in Table 1. Because of the complexity of the mechanisms of association, and as shown with o-LH[4], no straightforward interpretation of these parameters can be proposed. However, it is clear that the rate of the hybrid formation is intermediate between those for the two mother hormones whereas the activation enthalpy is very close to that for the fish hormone.

Thus differences in the structure of the α subunit do not seem to modify the influence of temperature on the association rate: the thermodependence of the reaction is determined solely by the β subunit. In contrast, not only the β subunit (as suggested from work on mammalian hormones[11]) but also the α subunit, contribute to determine the association rate at a given temperature.

We thank Dr J. Pierce (UCLA) for providing b-LH α. This work was supported in part by grant 77-7-0649 from DGRST.

GABA-mediated biphasic inhibitory responses in hippocampus

B. E. Alger & R. A. Nicoll

Departments of Pharmacology and Physiology, University of California, San Francisco, California 94143

γ-Aminobutyric acid (GABA) can have a biphasic effect on membrane potential when applied to certain central nervous system neurones[1–3]. Typically with iontophoresis, this effect is a negative–positive sequence of deflections and both phases are associated with an increase in conductance. However, iontophoretic application of neurotransmitter substances can produce effects even in cases where ordinary synaptic transmitter release is impossible; for example, on dorsal root ganglion cells. Thus, it is important in assessing the physiological relevance of the depolarising GABA response to determine if similar actions are produced synaptically. In addition, although the depolarising aspect of the GABA response has been attributed to activation of dendritic receptors, this identification has remained uncertain. Here, we have used the hippocampal slice preparation to demonstrate that a biphasic inhibitory response results from orthodromic, but not antidromic electrical stimulation in the presence of anaesthetic concentrations of pentobarbital. (For the sake of brevity, we use the term 'biphasic inhibitory postsynaptic potential (i.p.s.p.)' to describe the response complex, although it seems likely that a combination of two distinct events, rather than two parts of a single event, occurs.) GABA antagonists and tetrodotoxin (TTX) were used to show that the depolarising phase is due to synaptically released GABA acting on dendritic sites in the CA1 region. Both negative and positive phases are associated with a large conductance increase, and both block cell firing, indicating their inhibitory nature. The ionic mechanism of the depolarising phase is not fully understood but seems to involve a chloride conductance increase. Although the functional significance of the depolarising sign of the i.p.s.p. is not clear, the dendritic location would provide very effective control over dendritic excitability.

The slice preparation we use has been described elsewhere[4]. The major modification adopted here is that slices are held fully submerged between two pieces of nylon mesh. This arrangement permits prolonged stable recordings and the evaluation of drug effects from a single cell in both control and drug conditions. To oxygenate the slices adequately, the temperature of the bathing medium was held at 28–30 °C (ref. 5). The medium consists of 116.4 mM NaCl, 5.37 mM KCl, 2.5 mM $CaCl_2$, 1.3 mM $MgSO_4$, 0.92 mM Na_2PO_4, 26.2 mM $NaHCO_3$ and 11 mM glucose. Forty-three cells from male Sprague-Dawley rats were selected for analysis. All impalements were maintained for at least 30 min with cell resting membrane potentials over 50 mV (mean 58.1, s.d. 5.2 mV), action potential amplitudes of 78.5 ± 11.0 mV and total neurone input impedances of 45.8 ± 17.0 MΩ. Conventional intracellular recording techniques were used.

Electrical stimulation of CA1 stratum (s.) radiatum produces an excitatory postsynaptic potential (e.p.s.p.) followed by a long hyperpolarising i.p.s.p. in CA1 pyramidal cells. If 10^{-4} M pentobarbital (a concentration within the range occurring during

0028–0836/79/390315—03$01.00

anaesthesia) is added to the medium, the hyperpolarisation is prolonged and usually followed by a depolarisation (5.5 ± 3.5 mV) lasting seconds (7.9 ± 3.3 s, $n = 18$; Fig. 1*a*). The depolarisation is more reliably elicited with strong rather than weak (near threshold) stimuli. Passage of a series of 100-ms current pulses across the membrane shows that the entire sequence is accompanied by a drop in membrane resistance (Fig. 1*b*).

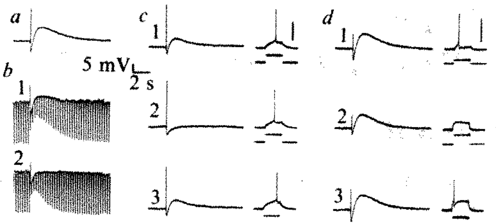

Fig. 1 Orthodromic production and dendritic localisation of depolarising i.p.s.ps in CA1 pyramidal cells. *a*, Orthodromic stimulation (s. radiatum) elicits hyperpolarisation followed by prolonged depolarisation. Resting potential (RP) −57 mV. *b*, Orthodromic and antidromic stimulation compared in a single cell. Downward deflections produced by hyperpolarising 100-ms current pulses (2 Hz) through a bridge circuit. Bridge balance was good. Reduced membrane resistance accompanies both responses; however, no depolarisation is seen with antidromic stimulation. RP, −59 mV. *c*, TTX (10^{-5} M) injected in the dendritic region abolishes depolarisation with no effect on hyperpolarisation. Action potentials produced by current pulses were unaffected immediately after TTX injection (c_2) although depolarisation was eliminated. The spike was subsequently blocked but recovered (c_3). RP, −63 mV. *d*, TTX injection in the somatic region greatly attenuates hyperpolarisation and blocks direct action potentials with little effect on depolarisation (d_2). Both hyperpolarisation and action potential recovered substantially (d_3). RP, −56 mV. All records were obtained in the presence of 10^{-4} M pentobarbital. Calibration for pen traces is 5 mV and 2 s. Calibration for oscilloscope traces is 40 mV and 1.0 nA. Current pulse duration is 100 ms in *c*, 30 ms in *d*.

GABA involvement in the depolarising phase is suggested by the observation that pentobarbital, which selectively enhances GABA action, is necessary to elicit it electrically. Further, perfusates containing GABA antagonists picrotoxin (10^{-5} M) or bicuculline (10^{-5} M) block the response ($n = 4$; data not shown) and, as seen below, iontophoretically applied GABA can mimic both hyper- and depolarising phases. These results strongly implicate GABA as the neurotransmitter for the biphasic action.

With iontophoretic pipettes independently positioned 200 µm within the slice at mid-dendritic and somatic regions, recording from a single cell shows that, even in the absence of pentobarbital, dendritic application of GABA produces a depolarisation whereas somatic application yields a hyperpolarising–depolarising sequence (Fig. 2*c*), as previously shown by others[2]. The interpretation of this pattern included the postulation of dendritic GABA receptors. Indeed, we have found that the depolarising action of GABA persists after synaptic transmission has been eliminated by changing to a low Ca^{2+} saline containing 8 mM Mg^{2+} ($n = 4$; data not shown), demonstrating that it is produced by receptors on the pyramidal cells themselves and is not an indirect effect. We hypothesised, therefore, that the electrically evoked, GABA-mediated depolarisation described above might represent a dendritic potential. To test this, we injected TTX (10^{-5} M) through a broken pipette, into the CA1 apical dendritic region. In four injections with three cells in which a large hyperpolarising–depolarising response was present, TTX selectively blocked the depolarising phase and its underlying conductance increase, but had little effect on the hyperpolarising i.p.s.p. or the action potential produced by somatic current injection (Fig. 1*c*). Neither resting potential nor input impedance changed and the TTX effect was reversible. The finding that the somatic spike was not altered at a time when the depolarising phase was blocked indicates that the depolarisation requires neuronal activity in the dendritic region. In the converse experiment, TTX injection through a pipette carefully positioned near the soma resulted in a complete block of somatic action potentials and substantial reduction in stimulation-evoked hyperpolarisation, without major effect on the depolarisation ($n = 4$; Fig. 1*d*). (Coarse TTX injections in the somatic, but not the dendritic, regions often resulted in the simultaneous reduction of both phases which may mean the cell whose synapses produce the depolarisation exists in or near s. pyramidale.) Taken together, the results with TTX injections imply that orthodromic stimulation in s. radiatum activates dendritic synapses which mediate i.p.s.ps having a depolarising component.

Both phases of the orthodromically activated response seem to exert an inhibitory influence on the pyramidal cell as measured by their ability to block action potentials caused either by intrasomatic depolarising current pulses or by e.p.s.ps (Fig. 2*a*,*b*). Similar blocking action is seen following iontophoresis of GABA on the dendrites (Fig. 2c_2,c_3).

It was often possible to see in a single cell a biphasic response to orthodromic (s. radiatum) stimulation and hyperpolarisation of shorter duration to antidromic (alveus) stimulation, the latter closely resembling the response to orthodromic stimulation following TTX application to the dendrites (compare Fig. 1b_2 and c_2). With very high intensity stimulation, small depolarisations could occasionally be elicited with antidromic stimuli, but current spread to known orthodromic fibres in nearby s. oriens[6] could not be ruled out in these cases. These findings indicate that orthodromic stimulation, in addition to activating the well documented recurrent inhibitory pathway[7], also activates a distinct set of inhibitory neurones which synapse on the dendrites of pyramidal cells and can have a depolarising action. We assume that pentobarbital merely emphasises a response which is normally present. That this drug is required to observe the depolarising i.p.s.p. may be due to the marked prolongation of GABA action which would result in a partial temporal

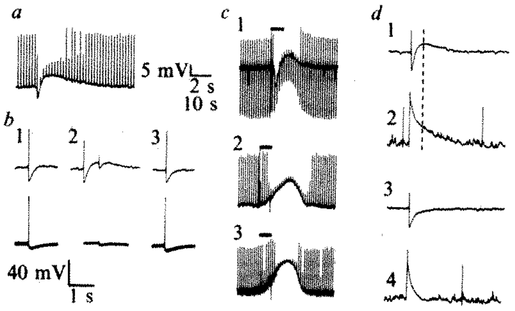

Fig. 2 Inhibitory effectiveness and chloride dependence of depolarising i.p.s.p. *a*, A train (2 Hz) of depolarising current pulses initiated full-sized somatic action potentials (amplitudes not accurately reproduced by pen recorder) which were blocked during most of the stimulation-evoked response. *b*, Inhibition of spikes elicited by just supra-threshold e.p.s.p. during a depolarising i.p.s.p. (b_2). Unconditioned control responses shown before and after inhibition (b_1 and b_3). Same cell as in *a*. RP, −59 mV. *c*, Effects of iontophoretic GABA (1 M) (horizontal bar) in normal medium without pentobarbital. c_1, Application through pipette in s. pyramidale. 100-ms current pulses given at 1 Hz (see Fig. 1b_1). RP, −55 mV. c_2, c_3, GABA iontophoresed in s. radiatum region of another cell. During depolarisation, both directly and synaptically activated action potentials are blocked (c_2 and c_3, respectively). RP, −61 mV. Iontophoretic pipettes were lowered independently 200 µm into the slice before impaling a cell. Ejection currents were 500 nA for 5 s. *d*, Two cells from the same slice in pentobarbital. d_1, Recorded with a 2 M potassium methylsulphate-filled pipette; d_2, with a 3 M KCl pipette. Note large amplitude and prolonged time course of depolarising response in d_2 after Cl$^-$ leakage into the cell. Small reversed i.p.s.ps visible on the baseline of the KCl-filled cell are capable of triggering action potentials. Antidromic responses from the same cells are shown for comparison (d_3, d_4). RP, −59 mV (d_1, d_3); −56 mV (d_2, d_4). Calibration for pen traces in *a*, *b* and *d* is 5 mV, 2 s; in *c* it is 5 mV, 10 s.

separation of the somatic and dendritic components. Assessment of the physiological role of the depolarisation will require more information on this point. The depolarising dendritic action of GABA in the absence of pentobarbital strengthens the notion that the dendritic i.p.s.p. normally has a depolarising component. A depolarising i.p.s.p., which is markedly enhanced by pentobarbital, has been reported to occur in olfactory cortical neurones[8].

The ionic mechanisms of the biphasic i.p.s.p. are not entirely understood. However, elevation of intracellular chloride by leakage from a 3 M KCl electrode reverses the hyperpolarisation and increases the positive phase of the i.p.s.p. ($n = 4$; Fig. 2*d*). This finding, in addition to the large conductance increase, suggests that chloride is at least partially involved in both phases. To account for the depolarising sign of the dendritic i.p.s.p., it must be assumed either that the chloride equilibrium potential is positive relative to the dendritic membrane potential, or that the conductance increase also involves other ions such as sodium or calcium. These cations alone could not be responsible for the depolarisation as excitatory, perhaps regenerative, activity would be expected to occur with a large increase in their conductances. Chloride plus either sodium or calcium currents could easily produce the observed phenomena. (Experiments like that of Fig. 2*b* imply that the depolarisation cannot be due simply to a depolarising shift in the local i.p.s.p. equilibrium potential, as in that case the superimposed test i.p.s.p. (Fig. 2b_2) would not be hyperpolarising.) Interestingly, Dudel has recently reported[9] that the inhibitory postsynaptic currents in crayfish muscle have a fast chloride conductance phase followed by a slower conductance phase which may involve an appreciable contribution of cations.

We have confirmed the presence of GABA-mediated dendritic i.p.s.ps and presented evidence suggesting these form an inhibitory system distinct from the classical recurrent pathway. We have demonstrated further that there is a depolarising aspect to the synaptically activated potential in pentobarbital which seems peculiar to the dendritic region. Differences in experimental species, temperature and recording conditions may all contribute to the fact that previous investigations *in vivo* did not report the depolarising component.

Although it seems clear that selective orthodromic activation of a dendritic i.p.s.p. would provide optimal control over local dendritic events[10], the functional significance of the depolarising phase is unknown. It is apparent that the pronounced conductance increase accompanying this depolarisation can predominate in inhibiting action potential generation. It remains possible, however, that the depolarisation could act to reduce the inhibitory effectiveness of the conductance increase.

The inhibitory neurones involved in the dendritic i.p.s.p. pathway have not been identified, although few cell bodies are present in s. radiatum. Possible candidates are the non-pyramidal cells which have somata near s. pyramidale and vertically orientated axons branching in s. radiatum[11-14].

1α,25-Dihydroxyvitamin D_3 and 24,25-dihydroxyvitamin D_3 *in vitro* synthesis by human decidua and placenta

Y. Weisman[*] & A. Harell[*], S. Edelstein[†], M. David[‡], Z. Spirer[§] & A. Golander[§]

[§]Department of Pediatrics, Rokach Hospital, Municipal-Governmental Medical Centre, Tel Aviv, Israel

The biologically active metabolite of vitamin D, 1α,25-dihydroxyvitamin D ($1\alpha,25(\mathrm{OH})_2\mathrm{D}$), is synthesised by successive hydroxylation of vitamin D in the liver and kidney[1]. The latter organ is the only known site of 1α-hydroxylation of 25-hydroxyvitamin D (25-OH-D)[2] and is also a major site of production of 24,25-dihydroxyvitamin D ($24,25(\mathrm{OH})_2\mathrm{D}$), a metabolite involved in bone ossification[3]. However, 24-hydroxylation of 25-OH-D may also occur in rat intestinal homogenates and in cartilage cells[4,5]. Accumulating data show that, during pregnancy, $1\alpha,25(\mathrm{OH})_2\mathrm{D}$ increases in the maternal circulation[6] but is absent or present only in small amounts in the fetus[7,8]. In comparison, $24,25(\mathrm{OH})_2\mathrm{D}$ accumulates in fetal tissues, particularly in the skeleton[8]. Little is known, however, about the independent metabolism of vitamin D in the fetoplacental unit. It has been reported[9] that the nephrectomised pregnant rat can synthesise $1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ and $24,25(\mathrm{OH})_2\mathrm{D}_3$ and that the fetoplacental unit is the most likely site of production of such metabolites. Those data suggested that there may be independent vitamin D metabolism in the fetoplacental unit. We now report *in vitro* synthesis of $24,25(\mathrm{OH})_2\mathrm{D}_3$ by human placenta and of $1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ and $24,25(\mathrm{OH})_2\mathrm{D}_3$ by human decidua. The human decidua is a development of the endometrium that is unique to pregnancy, originating from both epithelial and stromal cells and intimately attached to fetal structures, that is, the placenta and chorion.

Human placental, decidual and amniotic tissues from uncomplicated, full-term and from 8–12-week pregnancies were obtained within minutes of delivery or legal abortion and prepared for culture as described previously[10,11]. Explants of the tissues were cultured with RPMI 1640 medium (GIBCO) for 48 h and then incubated with tritiated 25-OH-D_3 for 24 h as described in Fig. 1 legend. At 72 h, the tissues and medium were extracted with chloroform–methanol[12]. The radiolabelled metabolites of vitamin D_3 in the lipid extracts were separated on columns of Sephadex LH-20 (Pharmacia), calibrated with authentic tritiated metabolites and developed with chloroform–petroleum ether (65 : 35, v/v) (Fig. 1).

Cultures of both full-term and young placental tissue synthesised $24,25(\mathrm{OH})_2\mathrm{D}_3$. The mean (±s.d.) percentage of tritium recovered from the Sephadex LH-20 columns as $^3\mathrm{H}$-$24,25(\mathrm{OH})_2\mathrm{D}_3$ was 6.97 ± 0.18 (full-term placenta) and 6.82 ± 1.23 (young placenta). Cultures of both full-term and young decidual tissue synthesised $1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ and $24,25(\mathrm{OH})_2\mathrm{D}_3$. The mean (±s.d.) percentage of tritium recovered from the columns as $^3\mathrm{H}$-$1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ was 3.65 ± 0.31 (full-term decidua) and 1.03 ± 0.61 (young decidua), and the percentage of tritium recovered as $^3\mathrm{H}$-$24,25(\mathrm{OH})_2\mathrm{D}_3$ was 3.12 ± 0.46 and 3.83 ± 0.41, respectively. Amniotic tissue did not synthesise either $1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ or $24,25(\mathrm{OH})_2\mathrm{D}_3$.

The identity of the putative $24,25(\mathrm{OH})_2\mathrm{D}_3$ and $1\alpha,25(\mathrm{OH})_2\mathrm{D}_3$ was established when samples from the fractions

0028-0836/79/390317—03$01.00

eluting from the Sephadex LH-20 columns in the positions of $24,25(OH)_2D_3$ and of $1\alpha,25(OH)_2D_3$ were applied to a high pressure liquid chromatography system (Fig. 2). The identity of the putative $24,25(OH)_2D_3$ was further defined by subjecting the $24,25(OH)_2D_3$ region to the periodate cleavage reaction[13], which resulted in the loss of radioactive label for the metabolite. In one experiment, 0.3 μg $[1,2\text{-}^3H,4\text{-}^{14}C]$25-OH-$D_3$ ($^3H/^{14}C$ radioactivity ratio 4.9:1, isolated from plasma of vitamin D-deficient chicks injected with $[1,2\text{-}^3H,4\text{-}^{14}C]$vitamin D_3) was incubated with pieces of decidua and the putative $1\alpha,25(OH)_2D_3$ was confirmed as a 1α-hydroxylated metabolite by calculating the reduction of the $^3H/^{14}C$ radioactivity ratio[14] (with a change in $^3H/^{14}C$ from 4.9 to 2.7). The *in vitro* synthesis of $1\alpha,25(OH)_2D_3$ by human decidua suggests that in pregnancy the kidney is not the only site of 1α-hydroxylation of 25-OH-D_3. In addition, the present study demonstrates that an extrarenal 24-hydroxylase activity exists in human placenta and decidua.

The findings reported here could be relevant to the understanding of the maternal–fetal interrelationships of vitamin D metabolism. For instance, the placenta could be a major source of the $24,25(OH)_2D_3$ accumulating in the fetus when maternal kidneys are programmed to synthesise $1\alpha,25(OH)_2D_3$. Another possible biological role for the 24-hydroxylase present in the placenta could be the 24-hydroxylation of $1\alpha,25(OH)_2D_3$, in a process similar to that which may occur in the rat intestine[4]. The 24-hydroxylation of $1\alpha,25(OH)_2D_3$, an important step in the inactivation of this metabolite[4,13], could explain the observation that $1\alpha,25(OH)_2D_3$ is undetectable or present only in small amounts in fetal tissues.

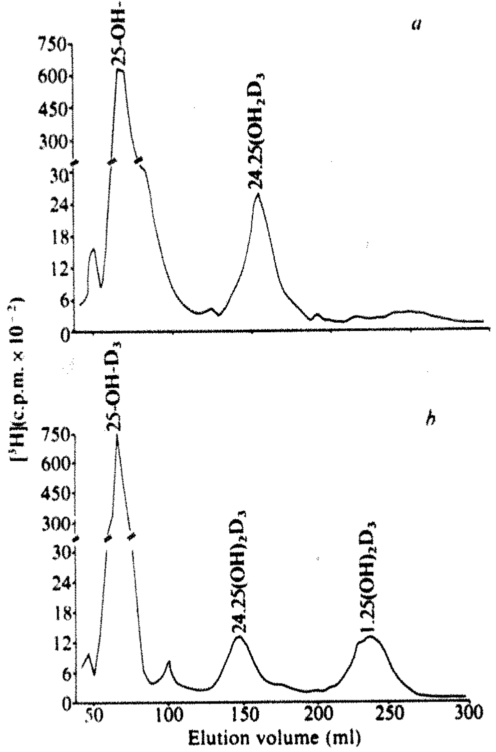

Fig. 1 Characteristic Sephadex LH-20 column chromatographic profile of extracts of full-term human placental tissue (*a*) and full-term human decidual tissue (*b*) incubated with tritiated 25-OH-D_3. Pieces (2 × 2 mm) of the tissues were prepared for culture as previously described[10,11], pooled to an average wet weight of 300 mg and cultured in incubation flasks with 15 ml of RPMI 1640 medium at 37 °C in an atmosphere of 95% air and 5% CO_2 for 48 h, with medium changes every 24 h. At 48 h, 10 pmol $[26,27\text{-}^3H]$25-OH-D_3 (Amersham, specific activity 9 Ci mmol^{-1}) in 0.01 ml ethanol were added to each flask. The tissue and medium were extracted at 72 h with chloroform–methanol[12]. The lipid extracts were chromatographed on a Sephadex-LH 20 column (60 × 1 cm), calibrated with authentic tritiated metabolites and developed with chloroform–petroleum ether (65:35, v/v).

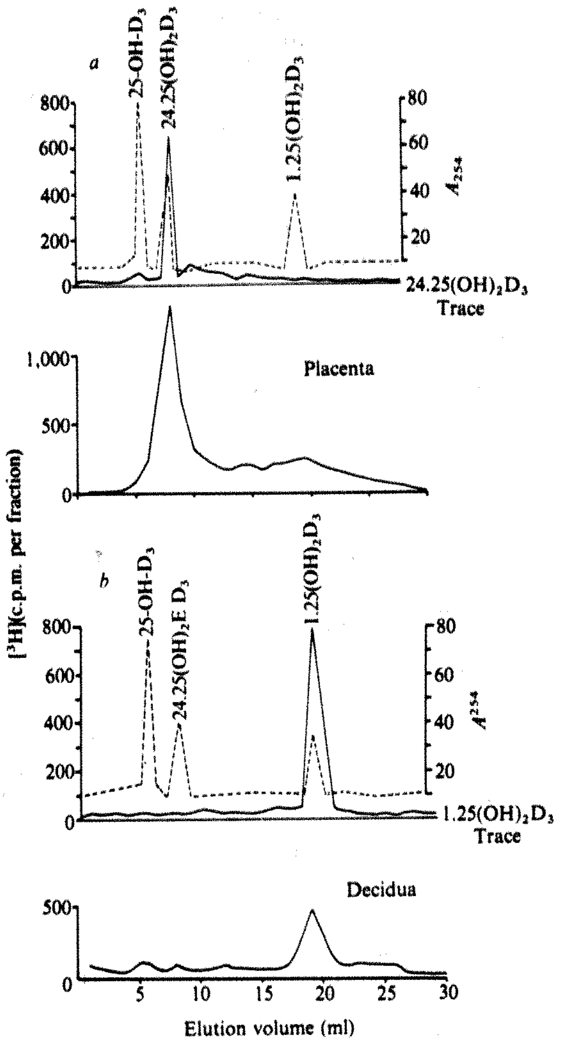

Fig. 2 *a*, High pressure liquid chromatography of the putative $(^3H)24,25(OH)_2D_3$ derived from Sephadex LH-20 columns, synthetic $24R,25(OH)_2D_3$ (----) and biosynthesised ^3H-$24,25(OH)_2D_3$ (——). Extracts of placental tissue incubated for 24 h with $[26,27\text{-}^3H]$25-OH-D_3 were chromatographed initially on Sephadex LH-20 (Fig. 1) and the region corresponding to $24,25(OH)_2D_3$ was then applied to high pressure liquid chromatography (a Waters Associates system fitted with μPorasil columns and eluted with isopropanol–hexane (1:9) with a flow rate of 1.0 ml min^{-1} at a pressure of 280 p.s.i.). A peak of radioactive material coinciding with standard $24,25(OH)_2D_3$ and biosynthesised ^3H-$24,25(OH)_2D_3$ is present. *b*, High pressure liquid chromatography of the putative $(^3H)1\alpha,25(OH)_2D_3$ derived from Sephadex LH-20 columns (Fig. 1*b*), synthetic $1\alpha,25(OH)_2D_3$ (----) and biosynthesised ^3H-$1\alpha,25(OH)_2D_3$ (——). Experimental details are as in *a*. A peak of radioactive material coinciding with standard $1\alpha,25(OH)_2D_3$ and biosynthesised ^3H-$1\alpha,25(OH)_2D_3$ is present.

Similarly, the roles of $1\alpha,25(OH)_2D_3$ synthesised by the decidua remain unclear. One possibility is that it contributes to the observed increase in $1\alpha,25(OH)_2D_3$ levels in the maternal circulation during pregnancy[6]. Alternatively, $1\alpha,25(OH)_2D_3$ synthesised by the decidua may be directly involved in regulating the active placental transport of calcium from the maternal circulation to the fetal compartment. A recent report demonstrating the presence of a placental calcium-binding protein similar to rat intestinal $1\alpha,25(OH)_2D_3$-dependent calcium-binding protein supports this assumption[15].

We thank D. Noff for assistance with the high pressure liquid chromatography.

The continuity of thick filaments between sarcomeres in honey bee flight muscle

K. Trombitas & A. Tigyi-Sebes

Central Laboratory, Medical University, Pecs, Hungary, 7643

One of the most frequently discussed problems of insect flight muscle morphology is the structure of the thick filaments, especially at the Z line. Many attempts have been made to solve these problems but no unequivocal answers have been given so far. It is well known that physiological specialisation is accompanied by certain anatomical features in the myofibrillar level; the myofibrils have very short I bands in the resting state and the muscle acts under nearly isometric conditions. In this paper, a fresh approach is used to demonstrate the fine structure at the Z line in honey bee flight muscle.

The appearance of the thick filaments and the Z line in insect flight muscles is quite different from that in vertebrate muscles. According to many authors[1-9] there are connections between the thick filaments and the Z line in stretched fibres. In common with all arthropod muscles the Z line consists of a hexagonal network[1,3,10-13] instead of a tetragonal one. The connections between the thick filaments and the Z line were termed 'connecting' filaments[14].

It is very probable that the connecting filaments not only extend to the Z line but also participate in its structure[12]. Consistent with this assumption, it is claimed that there is a continuity of the thick filaments from one sarcomere to the next across the thick filaments prolongations within the Z line[9,13,15,16]. The term 'thick filament' is used here in a structural sense and does not imply that the entire structure contains myosin. On the other hand, no evidence was found for the presence of connecting filaments in unstretched fibres[10,11,17].

Conflicting results have been obtained by electron microscopy of intact muscles using traditional methods (see refs 18 and 19 which present opposite conclusions in the same insect (water bug). Therefore, attempts are now being made to answer these questions using a different technique.

The study of the native isolated filaments can give valuable results for the elucidation of fine structure. Therefore filaments from the honey bee (*Apis mellifera*) flight muscle were isolated according to the method of Morimoto and Harrington[20] with a slight modification. The fresh dorsoventral flight muscles were slightly stretched and soaked in a low ionic strength medium consisting of 5 mM Tris-HC1 and 10 mM dithiothreitol, *p*H 7.8 at 2 °C. After 1 d the muscle was homogenised and centrifuged at 1,000 *g* for 10 min. Then the sediment was resuspended in low ionic strength solution. This procedure was repeated for 7 consecutive days. This period was sufficient to extract the M line material completely and the Z line material partially. Furthermore, an unusual gap or split[21] occurred in the centre of the A band at the level of the former M lines. The cause of the split is unknown, but thick filaments seemed to be completely several in this region.

Finally the myofibrillar mass was centrifuged and resuspended in relaxing medium containing 0.1 M KCl, 5 mM $MgCl_2$, 1 mM EGTA, 5 mM ATP, 20 mM potassium phosphate at *p*H 7.0. This suspension was homogenised three times for 20 s in a Waring blendor. The intact fibrils were centrifuged at 3,000 *g* for 15 min; the turbid supernatant contained isolated filaments. The thick filaments were separated from the thin filaments by zone sedimentation in a density gradient. The supporting solution was the relaxing medium and a linear gradient of glycerol from 10% at the top to 30% at the bottom of the centrifuge tube was used. A 4-ml aliquot of the filament suspension was layered in each tube. This system was centrifuged in a Spinco SW-27 swinging bucket rotor at 22,000 r.p.m. for 2 h. Six equal volume fractions were collected from each tube, and their biochemical composition was studied by SDS-polyacrylamide-gel electrophoresis[22]. The first two fractions contained a high amount of myosin and a low amount of 'unidentfied protein' (perhaps α-actinin, Fig. 1). The third fraction was almost free of protein. The fourth and fifth fractions contained a little myosin, but a high amount of actin. In the sixth fraction distinct and characteristic bands of myosin, paramyosin and actin were found.

A drop of filament solution was applied to a grid coated with carbon film and was negatively stained with 1% uranyl acetate. The first two fractions contained thick filaments. During intense homogenisation, the thick filaments were broken at the split of the former M lines but in every case connections remained at the level of the former Z lines between the very regularly tapered ends of two different thick filaments from opposite sarcomeres (Fig. 2). On several occasions the tapered end of a thick filament bifurcated at the level of the former Z line and joined with two different thick filaments from the adjacent sarcomere (Fig. 3). These intra-Z portions of thick filaments belong to the basic network of the Z line, they pass from one I-Z junction to the next at a slight angle joining the ends of two thick filaments from opposite sarcomeres. This finding correlates with earlier observations of the angling of the Z filaments in longitudinal sections[2,12,23]. Biochemical and structural evidence strongly suggests that this network does not contain actin. It is very probable that the 'unidentified protein' (perhaps α-actinin) can play an important role in the composition of this network, for it

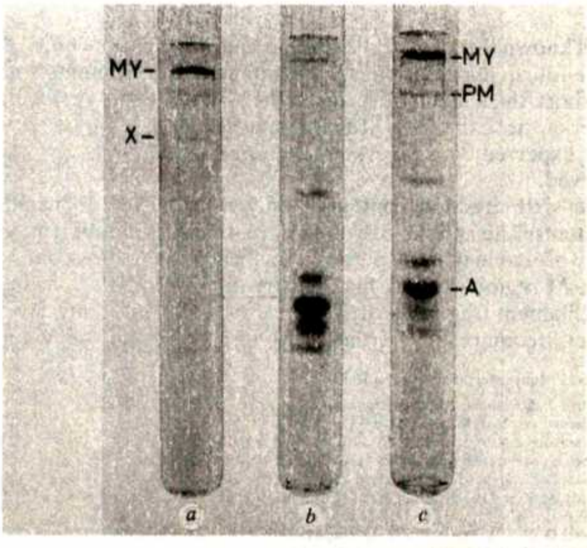

Fig. 1 Gel electrophoresis (10% gel) of sequential fractions obtained from zone sedimentation experiments; (*a*, second fraction; *b*, fourth fraction; *c*, sixth fraction. The bands that were identified by comparison with isolated proteins are marked as follows: A, actin; MY, myosin; PM, paramyosin; X, unidentified protein.

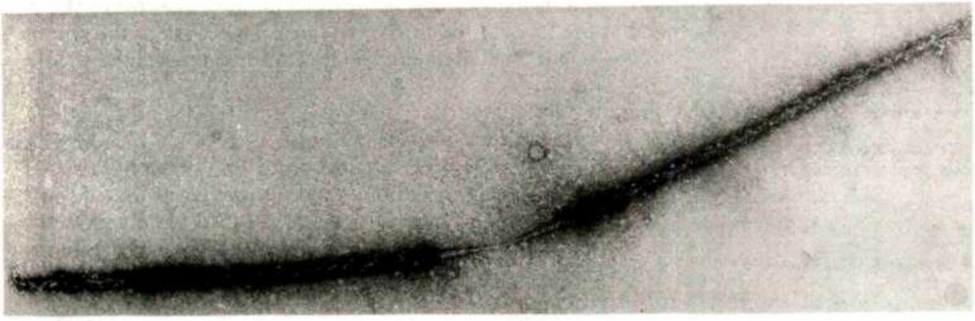

Fig. 2 The very regular tapered ends of two different thick filaments from adjacent sarcomeres, showing them to be connected (×100,000).

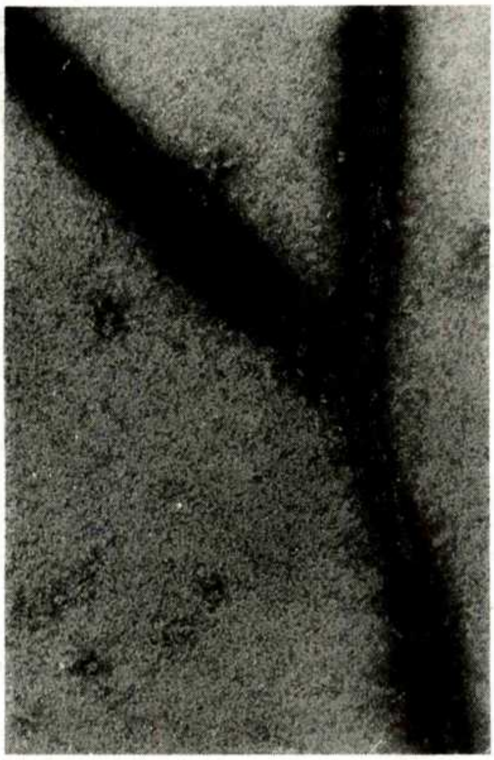

Fig. 3 A single thick filament bifurcated at the level of a Z line and joined with two different thick filaments from the opposite sacromere (×300,000).

is well known that the flight muscle Z line contains α-actinin[21,24].

The fourth and sixth fractions contained thin filaments and a few short thick filament fragments. According to Ashhurst's model of the Z line[10,11,18] thin filaments 1.3 μm long or shorter were expected. However, much longer thin filaments were observed.

The sixth fraction contained only thin and thick filament fragments. The appearance of paramyosin in this fraction makes it very probable that the paramyosin localisation[25–27] is confined to the M region of thick filaments in the bee muscle, since the thick filament fragments originate mainly from the central parts of the sarcomeres where they were disrupted near the M line.

The stereochemical course of amino acid activation by methionyl- and tyrosyl-tRNA synthetases

Simon P. Langdon & Gordon Lowe

The Dyson Perrins Laboratory, Oxford University, South Parks Road, Oxford, UK

Stereochemical analysis has long been recognised as a powerful tool for elucidating the mechanisms of chemical and enzyme-catalysed reactions. Although much is known about the stereochemical course of reactions at saturated carbon, phosphate and thiophosphate esters whose ligands to phosphorus are also tetrahedrally disposed, are capable in principle of revealing sterochemical information about events at the active site of enzymes that transform such substrates. Nucleotidyl transferases are a group of enzymes which in general selectively use one of the diastereoisomers of a nucleoside 5′(1-thiotriphosphate), such as isomers A and B of adenosine 5′(1-thiotriphosphate), designated ATPαS-A and ATPαS-B, and allow investigation of the stereochemical course of nucleotidyl transfer[1–3]. We have developed a simple method based on ^{31}P nuclear magnetic resonance spectroscopy for determining the stereochemical course of these reactions, and using this method show here that the nucleotidyl transfer step in two aminoacyl-tRNA synthetases from *Escherichia coli* occurs with inversion of configuration at phosphorus. These observations greatly constrain the mechanistic possibilities for these enzymes, and are interpreted most simply as a direct 'in line' transfer from ATP to the amino acid.

Aminoacyl-tRNA synthetases catalyse two distinct reactions, namely, amino acid activation by MgATP with formation of a mixed anhydride between the amino acid and AMP, and the transfer of the aminoacyl moiety of the aminoacyladenylate so formed to the cognate tRNA[4].

$$\mathrm{H_3\overset{+}{N}{\cdot}CHR{\cdot}CO_2^- + MgATP \rightleftarrows H_3\overset{+}{N}{\cdot}CHR{\cdot}CO{\cdot}AMP + MgPP_i}$$

$$\mathrm{H_3\overset{+}{N}{\cdot}CHR{\cdot}CO{\cdot}AMP + tRNA \rightleftarrows H_3\overset{+}{N}{\cdot}CHR{\cdot}CO{\cdot}tRNA + AMP}$$

Fig. 1 In an aminoacyl t-RNA synthetase-catalysed reaction between the cognate [$^{18}O_2$]-amino acid and ATPαS-A (1) in the presence of hydroxylamine, inversion of configuration at P_α leads to adenosine 5'[S-^{18}O]phosphorothioate and retention of configuration leads to adenosine 5'[R-^{18}O]phosphorothioate. These enantiomeric ^{18}O-phosphorothioates can be distinguished after conversion enzymatically to ATPαS-A (refs 6, 7), by determining whether ^{18}O is in the non-bridging (2) or bridging position (3), using ^{31}P NMR spectroscopy.

The amino acid activation step involves substitution at P_α in ATP, and study of the stereochemical course of this reaction should provide insight into the mechanism of this step as well as the geometrical relationship of the substrates at the active site of the enzyme. Thus, observation of net retention of configuration would be consistent with the intermediary of a nucleotidyl enzyme whose formation and breakdown follow the same stereochemical course, or an adjacent attack by the amino acid at P_α of ATP, followed by a single pseudorotation. Alternatively, net inversion of configuration would be interpreted most simply as a direct 'in-line' displacement.

If ATPαS-A (1) (Fig. 1), which is now known to possess the S-configuration at P_α (refs 3, 5), is an acceptable substrate for an aminoacyl-tRNA synthetase, incubation in the presence of the cognate [$^{18}O_2$]-amino acid and a high concentration of hydroxylamine should lead to the irreversible formation of the amino ^{18}O-hydroxamic acid and adenosine 5'[^{18}O]phosphorothioate (^{18}O-AMPS). If nucleotidyl transfer occurs with inversion of configuration at P_α, the *pro-S* oxygen would be labelled, whereas retention of configuration at P_α would place ^{18}O in the *pro-R* position (Fig. 1). Conversion of adenosine 5'-phosphorothioate (AMPS) into ATPαS-A by the combined action of adenylate kinase and pyruvate kinase involves phosphorylation of the *pro-R* oxygen[3,5]. Thus, if ^{18}O is present in the *pro-S* position in ^{18}O-AMPS, ^{18}O will be found in the non-bridging position at P_α in ATPαS-A (2) (Fig. 1), whereas if ^{18}O is present in the *pro-R* position in ^{18}O-AMPS, it will be found in the P_α–O–P_β bridge in ATPαS-A (3) (Fig. 1). These alternative possibilities can be differentiated by ^{31}P NMR spectroscopy[5], as ^{18}O in the P_α–O–P_β bridge produces an isotope shift on both P_α and P_β, whereas ^{18}O in the non-bridging position causes an isotope shift at P_α only.

L-[$^{18}O_2$]methionine (88 atom % ^{18}O) and L-[$^{18}O_2$]tyrosine (83 atom % ^{18}O) were prepared by acid-catalysed exchange between the L-amino acid and [^{18}O]-H_2O (99 atom % ^{18}O). A solution of L-[$^{18}O_2$]methionine (16 mg, 110 µmol), ATPαS-A (disodium salt, 42 mg, 75 µmol), magnesium acetate (17 mg, 75 µmol), Tris (242 mg, 2 mmol), hydroxylamine solution (4 ml, 15 mM, 60 mmol), phenylmethanesulphonyl fluoride (100 mg) and 2-mercaptoethanol (0.2 ml) in deaerated water (60 ml) at 37 °C was adjusted to *p*H 8.0 with 1 M HCl. Inorganic pyrophosphatase (0.5 mg) was added, followed by methionyl-tRNA synthetase (4 mg). The solution was kept at 37 °C for 48 h and the reaction terminated by addition of EDTA (120 µmol) and chloroform (10 ml). The aqueous phase was chromatographed on a column of DEAE-Sephadex A-25 (HCO_3^- form) at 4 °C, with a linear gradient of aqueous triethylammonium bicarbonate buffer (0.2–0.7 M, *p*H 8.0). Fractions containing ^{18}O-AMPS (54 µmol, this contained some unlabelled AMPS derived mainly from the hydrolysis of ATPαS-A during the incubation) were pooled and the buffer removed. It was converted to ^{18}O-ATPαS-A enzymatically[6,7]. P_α of the ^{18}O-ATPαS-A showed an isotope shift of 1.1 Hz (at 36.43 MHz) to higher field, where P_β showed none, demonstrating that the ^{18}O was in the non-bridging position at P_α.

Similarly, when L-[$^{18}O_2$]tyrosine (23 mg, 110 µmol) replaced L-[$^{18}O_2$]methionine and tyrosyl-tRNA synthetase (4 mg) replaced methionyl-tRNA synthetase, ^{18}O-AMPS (43 µmol, this contained some unlabelled AMPS derived mainly from the hydrolysis of ATPαS-A during the incubation) was obtained and converted enzymatically[6,7] into ^{18}O-ATPαS-A. Again, P_α showed an isotope shift of 1.1 Hz (at 36.43 MHz) whereas P_β was unaffected, demonstrating that the ^{18}O was in the non-bridging position at P_α.

These observations show that the nucleotidyl transfer step catalysed by both methionyl- and tyrosyl-tRNA synthetase from *E. coli* occur with inversion of configuration at phosphorus.

The simplest interpretation of these results is that nucleotidyl transer catalysed by these enzymes occurs by an in-line mechanism at P_α. Although more complex multi-step pathways (for example, three steps, each with inversion of configuration, or an adjacent attack with permutational isomerism) cannot be rigorously excluded, it seems unlikely that such mechanisms could occur in the confines of the active site of an enzyme.

We acknowledge a grant (to S.P.L.) from the Kent County Council, and a gift of the aminoacyl-tRNA synthetases from Dr C. J. Bruton. This a contribution from the Oxford Enzyme Group supported by the SRC.

Announcing the publication of

Current Genetics

Eukaryotes with
Emphasis on

Yeasts · Fungi · Mitochondria · Plastids

Title No. 294

Current Genetics is an international journal devoted to the rapid publication of original articles of immediate importance on genetics of eukaryotes, with emphasis on yeasts, other fungi, mitochondria and chloroplasts. Papers on formal genetics will only be accepted if they contribute to the understanding of special genetic systems and/or give access to molecular approaches.

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail): 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

EDITING SCIENTIFIC BOOKS AND JOURNALS
An ELSE–Ciba Foundation Guide for Editors
Maeve O'Connor
Senior Editor, Ciba Foundation, London

Following the success of 'Writing Scientific Papers in English' Maeve O'Connor has produced this new guide in collaboration with the Ciba Foundation and ELSE. Scientific editing is beset with problems but there have been few formal texts on either the rudiments of the subject or its finer points. This practical and authoritative book gives guidance in the editing of books, conference proceedings and journals. Written for scientist-editors in all fields of science and medicine, copy editors, publishers of scientific books and journals, any scientist interested in understanding how editors and referees work.

CONTENTS: Editing Outlined; Guiding Authors; Keeping Papers Moving; Working with Referees; Manuscript Editing: creative and substantive editing; Manuscript Editing: Technical editing; Completing Books and Journal Issues; Printing; Reading Proofs; Editing Conference Proceedings: a closer look; Starting a New Journal: financial aspects; Editing a Successful Journal; Editing in the Future: innovation and education.

reviews

Survey of medical history

Sydney Selwyn

Explorers of the Body. By Steven Lehrer. Pp. 463. (Doubleday: New York, 1979.) $12.95.

POPULAR accounts of medical history are surprisingly scarce. Before the appearance of Dr Lehrer's book, the only notable example of this rare genre was *Microbe Hunters*, which was first published over 50 years ago. The author, Paul de Kruif, was a lapsed bacteriologist whose highly coloured descriptions of heroic battles against infection fired the imagination of a wide audience. Indeed, many impressionable adolescents were inspired by his book to enter medicine and related professions.

Sadly, de Kruif's sequels on nutrition, psychiatry and other medical themes were progressively — perhaps predictably — less successful; and although he can be regarded as the main originator of the racy, home-spun style of medical journalism, which remains so popular in North America, it is puzzling that so few writers have attempted to emulate him with full length work in one of the most fascinating branches of human history. Since the 1920s an intermittent series of unexciting biographies has only occasionally been relieved by something as imaginative as *Rats, Lice and History*, written by another bacteriologist, Hans Zinsser. So barren and featureless has been the landscape, that this whimsical little book of 1935 still remains outstanding.

The publication of a reasonably comprehensive survey of medical history for the general reader is therefore to be cordially welcomed. Written attractively and with authority by a practising physician, this new book builds up a mosaic of the lives and work of innumerable contributors to the development of medical science. Four central chapters out of ten are devoted to infection and its control, the remainder being idiosyncratically arranged, starting with physiology, moving to genetics and then anaesthesia. Surgery is embedded among the infections, and the book ends with X-rays and diabetes mellitus.

The opening chapter on the evolution of knowledge about the functioning of the body forms a very satisfying prelude to this vast epic. From the stumbling observations made in Ancient Greece and Rome on the action of the heart and on respiration, progress is clearly traced through the late Renaissance to the work of William Harvey and a succession of other pioneers. Many of them were not primarily interested in medicine, for example, Boyle, Hooke, Priestley and Black in Britain, and Lavoisier and Laplace in pre-revolutionary France. As an incidental feature, the often uncomfortable (and occasionally fatal) effects of politics on the lives of medical explorers are curiously evident in this introductory section.

Similarly, in the two subsequent chapters fresh insight is provided into such well rehearsed stories as the work of Mendel, the elucidation of the structure of DNA, the acrimonious and complex background to the introduction of anaesthetic gases, and the rise and fall of mesmerism. Although inevitably told with less verve than in de Kruif's pages, Dr Lehrer's accounts of microbe hunting and taming make compelling reading. Particularly vivid are his descriptions of vaccines, antimicrobial drugs and, indeed most other medical advances.

A special feature of the book is its very revealing portraiture of major and minor participants alike, While most are necessarily depicted with the economy of a miniaturist, so extensive yet compact a gallery is unprecedented. Even the cognoscenti will probably realise for the first time just how disagreeable the average medical pioneer is. For every saintly figure such as William Withering or Paul Ehrlich, the author delineates dozens of irascible, bombastic, unscrupulous, or at the least, devious individuals such as Paracelsus, Hooke, Priestley, Erasmus Darwin, Semmelweis, Mendel, Pasteur, Koch, Cushing, Behring, Ross, and a handful of more recent Nobel laureates.

Sometimes, however, debunking seems to be indulged in for its own sake. For example, Harvey is said to have "lacked the ability of a skilled experimenter" because he considerably underestimated the body's total blood volume (which even now is difficult to measure). Edward Jenner is also criticised on the rather tenuous grounds that he did not publish details about the death of one of his patients, who seems to have succumbed to an unrelated "infection". A further criticism is that Jenner regarded cowpox and a comparable infection of horses as being closely related both to one another and to human smallpox — which indeed is in accord with modern virological views. But after the uncritical recent apotheosis of Harvey during the celebrations of his 400th anniversary, and the sustained adulation of Jenner during the past 150 years, fair re-evaluation of their work is very welcome. The text contains relatively few typographical or factual errors, and solecisms such as the statement that the French Academy of Sciences was, in the eighteenth century, "the final authority in European medicine" are mercifully rare.

The reader may well be disappointed to find virtually no mention of pathology, pharmacology and several medical specialties, including psychiatry — the "Explorers of the Body" being zealously prevented from entering the domain of the mind. An account of some of these important subjects could well have replaced the largely non-medical section on genetics. Nevertheless, the author has accomplished a *tour de force*, and his publishers also deserve praise for producing this admirable book at so reasonable a price. ☐

Sydney Selwyn is Reader in Medical Microbiology at the Westminster Medical School, University of London, UK.

What world food crisis?

Nutrition and the World Food Crisis. By Mary Alice Caliendo Pp.368. (Collier-Macmillan: London, 1979.) £5.95.

ONE function of the applied scientist is to warn his fellow man of possible impending doom, but there is a very real danger of loss of credibility if "Wolf!" is cried too often. There has been a spate of books forecasting food shortage and mass starvation over the past fifty years (two hundred if one counts Malthus), but although the situation is bad it has not noticeably become worse: food production per head of population has remained almost constant. Indeed, there has been a growing realisation that there is more than enough food about and that the real problem is that the poor cannot afford to buy their daily bread.

Food requirements are about 2,000 kilocalories per day per man, woman and child, and global agriculture produces something in excess of 4,500 kilocalories per head per day of crops suitable for human consumption. Much of this food is used inefficiently for the feeding of livestock to provide animal products for the rich, but even so there is about 2,500 kilocalories per head per day available for human consumption. So, please let us not hear about the 'World Food Crisis'.

All the evidence suggests that farmers can cope with the supply problem providing it is made worth their while. Malnutrition is not a supply problem: essentially economic demand does not equal physiological need. Very roughly half the world is underfed and the other half overfed; and it can be shown that the diseases of affluence — for example, obesity, heart disease, dental caries — are numerically of the same order as those associated with undernutrition. This poor distribution of wealth between nations is of course exacerbated by a further poor distribution within nations, which can lead to local famines. But even in the oft cited Ethiopian famine there was no shortage of food in the country as a whole: the rains failed in one area and the subsistence farmers there did not have enough money to buy food from the market in Addis Ababa.

Nevertheless, the International Agencies constantly document the wide extent of malnutrition in the world and proffer much advice on what to do about it. Not surprisingly this advice is not always consistent: experts often see things from their own narrow viewpoint, and generalists who can grasp technical, economic, social, cultural and political aspects of a problem are rare and often under-rated. Dr Caliendo has made a bold attempt to gather the relevant material, especially that since the 1974 World Food Conference. But sadly the inconsistencies have not been analysed critically or even pointed out. The need to increase food production is stressed in one chapter, but the next on distribution begins with the statement that production is about twice that needed. In chapter 2 the misplaced emphasis in the past on the role of protein in the aetiology of malnutrition is revealed, but in chapter 12 protein-rich foods are promoted. The importance of socio-economic factors is stressed in chapter 10 but their relevance to infant feeding practices in chapter 9 is not adequately discussed: bottle feeding is adopted by many intelligent mothers because it enables them to go out to work and thus improve the economic (and nutritional) status of their families. The current fashion for national food and nutrition planning is outlined but the fact that developed countries eliminated undernutrition without it is not mentioned, nor are we given one example that it has worked anywhere. Food aid is documented without definition nor mention that it is rarely food and seldom used to feed hungry people. These few examples are a true reflection of the inconsistency of the documents available, but perhaps it would be strange if such a complex problem as world hunger were to have a single simple solution.

Many modern texts are collections of papers by various authors often from Symposia and have the disadvantage that the information is not integrated as in good old-fashioned textbooks. Dr Caliendo has sadly not grasped the opportunity to do this but tries to be all things to all men. It is difficult to see where she stands herself. The book is aimed to "provide educators and students with substantive and practical information" with a view to "make it easier to learn about the problems of global hunger and nutrition". There is no doubt that it is a most useful compendium of information but because it is so uncritical I suspect it will confuse all but the brightest student. However, the book is cheap, extremely well illustrated with photographs, tables and graphs, and a jolly good read.

Einstein's influence on politics and philosophy

Albert Einstein: His Influence on Physics, Philosophy and Politics. Edited by P. C. Aichelberg and R. U. Sexl. Pp. 220. (Friedr. Vieweg: Wiesbaden, Germany, 1979.) DM48.

I NEVER really liked C.P. Snow's theory of the Two Cultures. In the United States of the 1950s and 1960s it seemed to me that scientists had a good grasp of politics and that liberal arts graduates were genuinely interested in and capable of understanding the main lines of scientific development. But perhaps the only way to understand the durability of the myth of Einstein as a socially naive genius is to accept Snow's basic assertion — there exist two cultures, literary and scientific, whose members cannot talk to each other. On the science side, Einstein's physics continues to mystify the general educated public. And on the arts side Einstein's politics remain incomprehensible to scientists who invariably characterise him as being naive when they write about his life.

The present volume of essays, commissioned by the International Society on General Relativity to celebrate Einstein's centenary, misses its chance to balance the picture. Editors Aichelberg and Sexl state in their introduction that the collection demonstrates the "far reaching influence of Einstein's work and his personality on physics, philosophy, theory of science and on the politics of our time". I believe that such a demonstration is possible. But this collection fails in its attempt to present a comprehensive view of Einstein's influence because much of the physics reported will be understood only by specialists and because Einstein's politics and philosophy receive the usual banal characterisation. The editors re-express the old cliché. Einstein's philosophical directness is "naive" and "this naivite is also characteristic for Einstein's involvement towards politics in which he was increasingly involved in his later years". The summary is wrong on both counts and it is time to do better.

Einstein was involved in politics from at least 1914 onwards and his political actions throughout his life reflected a highly sophisticated socialist's understanding of what was possible for a man in his position to do at any time. Beginning with the courageous anti-War manifesto in Berlin in 1914 which attacked the extreme national chauvinism of War-time Germany, and ending with his support for Julius and Ethel Rosenberg executed in the US for conspiracy to commit treason in the McCarthyite hysteria of the 1950s, Einstein intervened consistently against militarism, racism and fascism. And though his actions have seemed quixotic to close colleagues such as Max Born, they were informed by a detailed socialist analysis of the workings of class society.

It is possible to indicate only briefly the depth of Einstein's approach. Here is his summary of an analysis called "Why Socialism" that he wrote in 1949 for the influential US magazine, *Monthly Review:*

> "The situation prevailing in an economy based on the private ownership of capital is thus characterised by two main principles: first, means of production (capital) are privately owned and the owners dispose of them as they see fit; second, the labour contract is free. Of course there is no such thing as a *pure* capitalist society in this sense. In particular it should be noted that the workers, through long and bitter political struggles have succeeded in securing a somewhat improved form of the 'free labour contract' for certain categories of workers. But taken as a whole, the present day economy does not differ much from 'pure' capitalism".

Einstein was clear about the solution to the problems that this social arrangement causes:

> "I am convinced that there is only *one* way to eliminate these grave evils, namely through the establishment of a socialist economy accompanied by an educational system which would be oriented towards social goals".

These are not the views of a neophyte. Far from being naive, Einstein's radicalism contrasts favourably with the results achieved by the inept liberal nationalism of the German scientific elite. Professor Carl-Friedrich von Weizsäcker's piece on Einstein's politics illustrates the gap between the approaches. For von Weizäcker it was Einstein's "aloofness" not his greater political understanding that permitted Einstein to act politically while others, as von Weizsäcker puts it, "conceded — apparently or truly — to believe in the political prejudices of the time in order to function concretely in their midst".

Similarly Banesh Hoffman presents only a superficial view of Einstein's Zionism by failing to situate Einstein's support for the state of Israel in the context of the intense anti-semitism of Europe between the Wars. As Einstein said in 1938:

> "Rarely since the conquest of Jerusalem by Titus has the Jewish community experienced a period of greater oppression than prevails at the present time".

Einstein supported the Zionist cause pragmatically and I think it is a mistake to present him as a narrow nationalist. This was his appraisal of the situation in 1930:

> "I saw how schools, comic papers and innumerable other forces of the Gentile majority undermined the confidence of even the best of my fellow-Jews and felt that this could not be allowed to continue. Then I realised that only a common enterprise dear to the heart of Jews all over the world could restore this people to health".

But in spite of the fact that the collection does not live up to the promise of its title there is still much to interest the casual reader. Dennis Sciama offers a nice concise review of the current position in cosmology and Roger Penrose delivers an informative and very nearly comprehensible account of black holes. And of continuing interest are the personal reminiscences of Einstein. Walther Gerlach on Einstein and quantum theory and John Wheeler on Einstein's Princeton days are new additions to the Einstein archive. Particularly welcome is the inclusion of Einstein's last lecture which along with the transcript of his answers to the questions give a vivid picture of Einstein in action as a thinker. Finally, Wolfgang Yourgrau's portrait, "Einstein — and the Vanity of Academia" is a fresh and irreverant view of the German academy in the 1920s. Yourgrau may have gone too far in reporting his mother's shocked observation that Einstein had dandruff, but I think Einstein would approve. The idea of a god with dandruff would have amused him immensely.

Joe Schwartz

Joe Schwartz is on leave from the City University of New York.

Communicative abilities

Studies of Language Thought and Verbal Communication. Edited by R. Rommetveit and R. Blakar. Pp. 466. (Academic: London and New York, 1979.) £22.80.

OVER the past 20 years Rommetveit has been developing a particular approach to the psychology of language, thought and communication. He calls his position a "social-cognitive" one and it contrasts in particular with the psycholinguistic-experimental approach with its focus on single sentences. Rommetveit has always held that such an approach has led to gross simplifications which could never be of use in comprehending the complexities of the mechanisms underlying our communicative abilities.

This book is a collection of articles by Rommetveit and his collaborators in Oslo. It is a mixture of theoretical statements and experimental articles. The 35 articles are of very mixed value and there is little attempt to link together the varied work which ranges from word recognition to the verbal maintenance of sex rules in Norwegian. The experimental section of 27 articles would have benefited from severe pruning.

There is better value in the theoretical articles (most of which are not easily available in their original places) where Rommetveit draws on a number of linguistic and philosophical traditions in discussing the nature of language and communication and moving over into hermeneutics and social psychology. I didn't always succeed in understanding, and quite frequently disagreed but found myself stimulated agreeably often. However, Rommetveit never achieves the synthesis he aims for.

John Morton

John Morton is a member of the scientific staff of the MRC Applied Psychology Unit, Cambridge, UK.

Vibrations of molecular crystals

Molecular Vibrations in Crystals. By J.C. Decius and R.M. Hexter. Pp. 391 (McGraw-Hill: New York and London, 1979.) £15.60; $29.50.

MANY textbooks discuss in considerable detail the lattice vibrations of simple covalent and ionic crystals but this book is unique in dealing with the vibrations of molecular crystals. As these are of the type that most chemical solid-state spectroscopists deal with, this book will be of interest and value to the growing number of scientists who study experimentally the vibrations of molecular crystals using infrared, Raman or neutron spectroscopy or to theoreticians carrying out lattice dynamical calculations on molecular crystals. It is jointly written by two authors with an international reputation for their contributions to the vibrational spectra of molecular crystals using infrared spectroscopy. In many ways the book is a natural extension of the now classic work on *Molecular Vibrations* by Wilson, Decius and Cross (McGraw-Hill) which deals with isolated molecules.

The original approach used in this book is to emphasise a representation based on internal coordinates and thus to take advantage of molecular integrity where it is appropriate, but to permit its modification by perturbation theory. In the internal coordinate representation the dynamical matrix becomes the familiar FG matrix of Wilson, Decius and Cross. A new method of calculation of this matrix, valid throughout the Brillouin zone is developed in this treatise.

Many chemical spectroscopists are not familiar with the splitting of longitudinal and transverse optical modes; they will therefore find useful the review of this important topic which is treated both from the traditional macro-scopic point of view as well as with microscopic theory. This has not previously been so carefully done.

Six different molecular crystals (HCN, CO_2, CHI_3, NaN_3 and $NaClO_3$) are used as detailed examples to consider infrared and Raman spectra and their selection rules. In all cases, spectra are discussed with respect to crystal splittings and polarisations. The current theories of these splittings are carefully examined, compared and evaluated in molecular as well as in ionic crystals. The expression of intermolecular coupling of vibration in both excitation and phonon coordinates is contrasted, and the basis and extent of their equivalence is discussed.

The theory of multiphonon spectra is thoroughly reviewed, covering selection rules, intensity distribution and origin in crystal anharmonicity. The Van Hove and Phillips theories of critical points are carefully explained. In one example, Iodoform-calculated phonon dispersion curves are presented and their consequences are compared with experiment.

In the final chapter, the spectra of impure crystals, both ionic and molecular, are discussed, together with a simple introduction to Green's function treatment of isotopically impure crystals.

The authors are to be congratulated on producing a well written definitive work that will appeal to physicists as well as chemists interested in molecular crystals. This book is likely to prove useful as a text for postgraduate courses on infrared and Raman spectra of solids, self-study reading for students starting research in the subject and as a guide to the extensive literature in this field.

G.R. Wilkinson

G.R. Wilkinson is Professor of Physics at King's College, University of London, UK.

Psychosocial evolution

Sir, — In his review of Garland Allen's *T.H. Morgan: The Man and His Science* (see *Nature*, **278**, 786-787; 1979), Professor Darlington makes several very cogent points. Perhaps the most illuminating of all are his remarks about the relations between Morgan, Wilson and Bateson, which are especially valuable in view of the fact that he knew all three men. It is therefore a great pity that, simply for the sake of taking a rather poorly aimed pot-shot at Allen's Marxism, Professor Darlington drags in the *canard* of "Lamarckism and Lysenkoism", alleging that both Morgan and Julian Huxley opened the door to these horrors. I do not have Morgan's *Scientific Basis of Evolution* to hand but what Huxley says on psychosocial evolution in *Evolution: The Modern Synthesis* (Allen and Unwin: London; second edition, 1963, pp. xliv - xlvii) in no way justifies this charge. It might be objected that "psychosocial evolution" is a cumbrous and pretentious phrase for a very simple and obvious phenomenon. Indeed, I would myself prefer simply "cultural evolution", or the phrase that Huxley used elsewhere in a popular essay (*The Uniqueness of Man*; Allen and Unwin: London; 1941): "cumulative tradition". The idea is a commonplace, for which a list of 'sources' would be neither necessary nor practicable. This is itself sufficient reason for Huxley not having mentioned Morgan in this connexion. To argue that, because of its radically different nature, it should not be regarded as a form of evolution or of heredity would be difficult in view of the dictionary meanings of those words.

A belief in psychosocial evolution is perfectly compatible with the belief that heredity, in the genetical sense, is diamond-hard. For Professor Darlington to pretend otherwise is just as absurd as it is for Arthur Koestler (*The Case of the Midwife Toad*; Hutchinson; London, 1971) to claim that Waddington's work on genetic assimilation was a vindication of Lamarckism. Nobody who approaches either human history or what is going on in the world today with a relatively unprejudiced mind can doubt that psychosocial evolution is both real and important. To create a false link with Lamarckism is merely to hand the argument to the Lamarckians on a plate.

A.G. Cock

A.G. Cock is Lecturer in the Department of Biology, at the University of Southampton, UK.

Cock on evolution

Dr Cock complains that I have wrongly connected the evolutionary views of Morgan and Huxley. And also wrongly connected them with the theories of Lamarck and Lysenko and with what I called the "froth" of our social sciences today. These ideas, he says, are "commonplace" and it is not "necessary or practicable" to trace them to their roots. I, however, think it necessary to trace all ideas, scientific or political, true or false, to their roots. I have been trying to do so for over fifty years. May I show how it works?

There were two roots in this case. Morgan had used his reputation as the supposed creator of the theory of heredity to advance a false theory of heredity and evolution in man. And Julian Huxley had used his name to repudiate his grandfather's work in *Man's Place in Nature;* he was therefore able to present himself as the Darwinian who had discovered that after all we need not worry: Darwinism did not apply to man.

Take Morgan first. I did not seriously look at his book when he gave it me in 1933 (I don't think he looked at my book either). But there it stands. It expresses the main fallacies current in human evolutionary thought today. The first fallacy is that "There are in man two processes of inheritance: one through the physical continuity of the germ-cells; and the other through the transmission of the experiences of one generation to the next". The physical inheritance gives you 3:1 ratios and dogmatic truth of interpretation. It applies to bodily characteristics. But (and here is the second fallacy) it does not apply to the brain: "It is the plasticity of man's brain that makes him unique". Then Morgan naturally asks: "Is intelligence inherited?". How can we be sure? There is nature and nurture. And there may be conflict between them. Worse still, there is "the doctrine that all men are born free and equal". All the issues are avoided. All the fallacies are scrambled.

Three years later (in 1936) this kind of loose talk had become dangerous. In Europe genetic assumptions were being turned to political uses. Half-baked genetic ideas were helping us on the way to war. In this country a particular danger concerned me. Genetic teaching and research hardly existed in our universities. I therefore collected university signatures for a letter in *Nature* (**138**, 972-973; 1936) protesting against academic stagnation in this vital respect. I also turned to Huxley who had been aggressively defending the Mendelian and Darwinian positions at the British Association. I persuaded him to edit an international symposium on the developing situation in evolutionary theory. He agreed. But by the time the book appeared in 1940 (under the title of *The New Systematics*) I discovered that Huxley was easing out of the genetic problem so far as man was concerned. In *We Europeans*, followed by the *Uniqueness of Man* he was looking for a political way out: the kind of 'placebo' that Morgan had stumbled upon.

Faced with this confusion I tried to make my position clear in an article, or manifesto, under the heading of "Race, Class and Mating in the Evolution of Man" (*Nature*, **152**, 315-319; 1943). Here I discussed the complex and often reciprocal or feedback relations of race, culture and selection, as recorded in history but usually misunderstood by historians. I argued that inbreeding always produces groups or communities or races which are the indispensible agents of human evolution.

Each of these "owes its character to what we may call its chromosome pool". I went on to say that "race made culture and language" and that inbreeding led to "easy transmission of culture". In other words the creation and transmission of ideas were both based on hereditary abilities, and both were subject to genetic and selective Mendelian and Darwinian processes.

To justify these *ex-cathedra* statements I began to set out the historic and pre-historic record of human society in genetic terms. My first essay, *The Facts of Life*, I sent to Huxley in proof, as he had sent me the chapter of his *Evolution* dealing with my work. He made prodigious annotations, chiefly urging me to qualify my generalisations or weaken my conclusions. I kept the proof but did not adopt the suggestions.

During the next ten years we exchanged a hundred or so letters in which Huxley was enquiring about my views on genetic and evolutionary questions. At the end of this time (in 1963) he published a second edition of his *Evolution*, with a new introduction. Here he set out his full UNESCO formula. Now all peoples were to be reconciled to one another, prosperously united under the banner of inevitable scientific progress.

Man had entered a "psychosocial phase of evolution". Change was now "primarily cultural and only secondarily genetic". Each human population had, not my pool of chromosomes, but "a pool of ideas" on which it could draw "for its evolutionary requirements". It was obvious (as I explained in the *Times Literary Supplement* of 20 December, 1974) that in this pastiche Huxley had provided the world with a pool of ideas which would meet the "evolutionary requirements" of the social and political sciences for many years to come. Not that they would know (any more than Dr Cock does) what pool they were drawing them from.

For there was indeed another pool. The Soviet Government had repudiated Lysenko in agriculture. But Marxists throughout the world continued to draw what unity they had from one surviving belief, the belief that theories of evolution by natural selection did not apply to man. Anathema had been pronounced on 'Social Darwinism' and it could never be withdrawn. So abominable was this heresy that it must always be condemmed; and it must never be discussed.

For these reasons I thought it worthwhile to write another book, *The Little Universe of Man* (apparently unknown to Dr Cock but reviewed in *Nature*, **277**, 247; 1979). Here I argued in elementary terms my genetic view that intelligence is seated in the brian and that the brain is part of the body. Hence men differed in their ability to create culture, to acquire culture and to transmit culture. Not only men and women as individuals, but as families, classes and races, as sects and groups of all kinds, they differed genetically by their genes and chromosomes in their abilities to do these things. They always had differed and always would differ, a situation responsible for the past history, present state and future prospects of mankind.

In writing these things I took the opportunity again of holding up Huxley's views to the ridicule they invite and deserve. I also again returned to expose a minor fallacy of Morgan's which has left a long trail of error behind it. This is the view that all heredity is in the chromosomes and in the nucleus. And that therefore one-egg twins are always identical in heredity. Each step in this argument is false and the conclusion has been repeatedly falsified. But it had become, as I put it (*Nature* **234**, 521-525; 1971) "*axiomatic*". Because Morgan said it (although he also said intelligence could not be measured) all psychologists trying to measure intelligence have assumed it to be true — and that includes the late Cyril Burt. I therefore pointed out, first, that Galton, who first recognised one-egg twins, never made Morgan's mistake of supposing they were identical; and secondly, that there are two genetic ways, nuclear and non-nuclear, in which we know why they often cannot be identical. The likenesses of one-egg twins, whether measured in mind or body, remarkable as they are, thus always give an under-estimate of the effects of heredity; their differences always give an over-estimate of the effects of environment.

I may now go back to Dr Cock and his sources. I have found that whether in scientific, historical or any other discussion, it is always desirable to look for the sources, examine them, and question them; and each step in the argument that has led from them. And I believe it is because social and political scientists often fail to do so, finding that the knowledge is "commonplace", or the task not within their "frame of reference", or merely, following the eminent examples of Morgan and Huxley, that so much of what flows from their enquiries turns out to be froth.

PPOINTMENTS VACANT

CAPRICORNIA INSTITUTE OF ADVANCED EDUCATION

Rockhampton, Queensland, Australia

DEPARTMENT OF BIOLOGY

SENIOR LECTURER/ LECTURER

pplicants should preferably be from the eld of Applied Biology, have completed Higher Degree and possess relevant aching, industrial or research experience.

Preference will be given to candidates no satisfy these criteria in the fields of quatic Biology, Applied Psyiology or nvironmental Biology but all suitably alified applicants will be considered.

Current Salary Scales: Senior Lecturer 1,858 to $25,477 P.A.
cturer $14,041 to $21,401 P.A. ustralian)

Appointments are normally made on her a two or three year contract with a minating gratuity equivalent to 15% of al salary. For further information ntact Mr. Bryan Rothwell, Head of partment, Phone (079) 361177, Telex 49176.

Application forms may be obtained om The Registrar, C.I.A.E., ckhampton, Queensland, Australia, 00, with whom applications close on 28th tober, 1979. (M650). W384(A)

EXECUTIVE SECRETARY GEOLOGICAL SOCIETY

he Society has a membership of over ,000, of whom over 1,000 are resident verseas. It organises over 60 scientific neetings and courses annually, and as an expanding publications rogramme that includes two lourishing journals.

he Executive Secretary is head of a ermanent staff of 16 and is esponsible to the Council and onorary Officers for the day to day nanagement of the Society's affairs nd its long term development. The xecutive Secretary with his/her staff rovide the Secretariat for the Council nd for Committee Meetings, and is esponsible for implementing ecisions taken.

he post requires both a high degree of dministrative expertise, and the bility to represent the Society at all vels ranging between personal ontacts with individual visitors and ellows to dealings with industrial, overnmental and academic rganisations.

Applications are invited from ersons who have occupied senior ositions of responsibility in academic industrial environments. Starting lary £8,000 per annum.

pplication forms may be obtained om: Executive Secretary, eological Society, Burlington ouse, Piccadilly, London 1V 0JU. 3285(A)

UNIVERSITY OF EXETER

DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited from Biochemists for the post of

RESEARCH DEMONSTRATOR

in the Department of Biological Sciences, tenable from 2 January 1980. The post is for two years in the first instance. Salary, depending on qualifications:

	Pre-doctoral	Post-doctoral
First Year	£3,775	£4,333
Second Year	£4,055	£4,622 (under review)

plus USS membership

Further particulars obtainable from Miss Doreen Watson, Northcote House, Queen's Drive, Exeter, to whom applications (five copies) with the names of three referees, should be sent by 1 November 1979. Please quote reference No. 7161. Short-listed candidates will be invited for interview on 28 November.
3280(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

ELECTRON MICROSCOPY UNIT

Institute of Dermatology London E9

(University of London)

A post-doctoral research assistant is required to work on a project on cutaneous vascular responses to injury. The appointment will be for two years in the first instance with possibility of extension for a further year. Experience in E.M. techniques is essential. Starting salary £4,333 to £4,910 plus L.W. (£502) p.a.

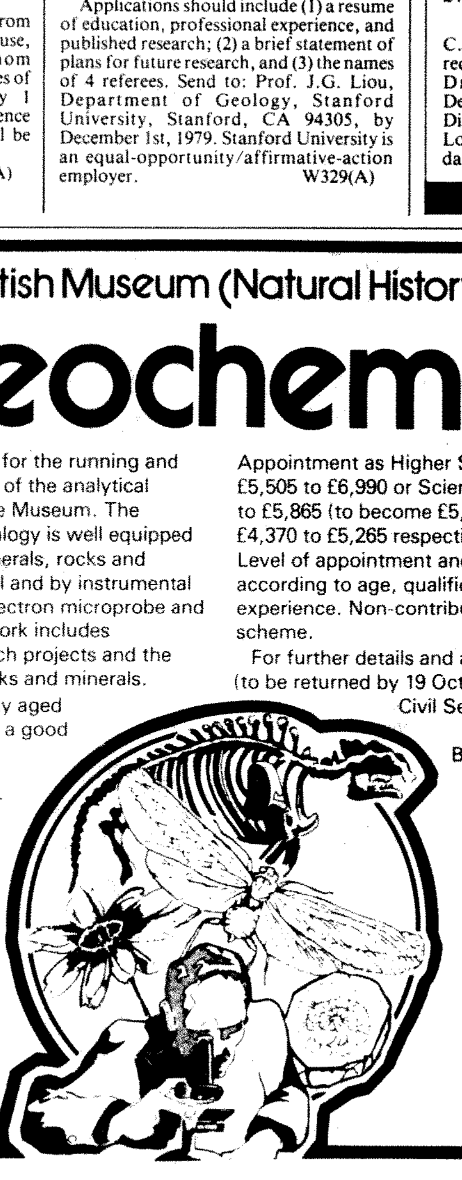
Address applications, including full C.V. and names of two referees, or requests for further information, to Dr R A J Eady, Institute of Dermatology, St John's Hospital for Diseases of the Skin, Homerton Grove, London E9. Tel: 01-985 7061. Closing date is October 19th, 1979. 3268(A)

British Museum (Natural History)

Geochemist

. . . to be responsible for the running and development of some of the analytical techniques used in the Museum. The Department of Mineralogy is well equipped for the analysis of minerals, rocks and meteorites by classical and by instrumental methods, including electron microprobe and neutron activation. Work includes participation in research projects and the service analysis of rocks and minerals.

Candidates (normally aged under 30) should have a good honours degree in chemistry with geology; chemistry; or geology with ancillary chemistry. Applicants should also have received appropriate training in research methods of mineral analysis and geochemistry. Knowledge of computing methods would be advantageous.



Appointment as Higher Scientific Officer £5,505 to £6,990 or Scientific Officer £4,065 to £5,865 (to become £5,875 to £7,515 and £4,370 to £5,265 respectively from 1.1.80). Level of appointment and starting salary according to age, qualifications and experience. Non-contributory pension scheme.

For further details and an application form (to be returned by 19 October 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/64/DK.*

LIVER UNIT

Applications are invited for the post of

SCIENTIFIC RESEARCH ASSISTANT

to work as part of a multidisciplinary team investigating serological tumour markers. The successful candidate will be involved in studies on pancreatic carcinoma and will have had some prior experience in protein biochemistry and/or immunochemistry. There will be the possibility of registering for a higher degree.

Salary on the scale for Research Assistant Grade IB.

Applications, giving full curriculum vitae and the names and addresses of 2 referees should be sent to the Secretary of the Medical School as soon as possible.

3306(A)

AUSTRALIAN ATOMIC ENERGY COMMISSION RESEARCH ESTABLISHMENT
Lucas Heights — near Sydney

CHIEF
ENVIRONMENTAL SCIENCE DIVISION

Applications are invited for the position of Chief, Environmental Science Division at the Commission's Research Establishment at Lucas Heights, about 30 km south of Sydney. The appointee's primary responsibility will be to initiate and lead a vigorous multidisciplinary research program concerned with basic envirionmental principles and mechanisms.

The Division has a current staff of 20 professionals and 10 technical officers. At present the main emphasis in its work is related to uranium mining and processing. Research interests include meteorology, transport processes, surface and sub-surface hydrology, water quality, environmental economics, soil-solute chemistry, waste water treatment, radon dosimetry, radium ecology and the effect of heavy metals on aquatic fauna. The present program reflects the shorter term demands of uranium mining development but it is planned in the future to enter into a longer term research program to study basic principles and mechanisms and to anticipate demands of future nuclear and possible other energy developments. The Division is the major centre of research and scientific expertise in environmental aspects of nuclear activities in Australia and as such is involved in extensive advisory services and consultation with other governmental departments and industry. It also maintains liaison and cooperation with other national and international bodies on environmental and public health matters. The Division Chief will be responsible to the Director of the Research Establishment for the management of the Division, the development and leadership of its program and the maintenance of the highest standards in its work. The Division Chief will be expected to give advice within his or her areas of experience and competence on Commission policy and must be capable of establishing and maintaining the Division as a recognised authority in the field of environmental science.

Applicants should have high academic qualifications and experience in a field or fields relevant to the subject and have a proven record in research and research management. Salary will be:

CHIEF OF DIVISION, GRADE 1 $A32412

Application forms may be obtained by writing to the Counsellor (Atomic Energy), Australian High Commission, Australia House, Strand, London, WC2B 4LA, with whom applications will close on 12 October 1979.

3312(A)

DEPARTMENT OF AGRICULTURE FOR NORTHERN IRELAND

HEAD OF POULTRY DEPARTMENT
£7,350 — £8,722

Applications are invited for the pensionable post of Head of Poultry Department at Loughry College of Agriculture and Food Technology, Cookstown, County Tyrone.

The College offers Certificate courses in Agriculture, Ordinary and Higher National Diploma Courses in Food Technology and a Higher National Diploma in Poultry Husbandry. In association with Queen's University, Belfast, 3 courses at post-graduate level are provided. Two of these lead to the degree of MAgr (by examination) and are offered in Dairy Technology and Poultry Technology. There is also a course in Agricultural Communication which leads to the award of a University Diploma. A variety of other courses to meet the needs of the food production and processing industries is given as the need arises.

DUTIES

The duties of the Head of Department are:

(a) Organisation and supervision of all teaching within the Department.

(b) Organisation and supervision of the Poultry production and processing enterprises at the College.

(c) Organisation of the participation in applied research in poultry.

(d) Liaison with the Poultry Advisory Services of the Department of Agriculture, Northern Ireland in the provision of advice to poultry producers and processors.

Some additional supervisory and stand-by duties are involved. Research work may be submitted to the University for higher degrees. A modern residence is available if required.

QUALIFICATIONS

Candidates must have a first or upper second class Honours Degree or a post graduate degree considered to be of comparable value. The degree should be in Agriculture, Agricultural Science or Science or in a subject area which relates to the science and practice of poultry production and marketing. Extensive experience in teaching or research in poultry or a closely-related field is essential.

SALARY
£7,350 to £8,722

Starting salary will be related to qualifications and experience. The salary scale is under review from 1 January 1980.

In addition there is a non-contributory pension scheme apart from a 1½% deduction from salary to cover widow's and dependant's benefits in the case of male officers.

The Commissioners may decide to interview only those applicants who appear from the information available, including level of academic attainments and experience, to be best qualified.

Further details of the work of the College and its Poultry Department are available on request from the Principal, Loughry College of Agriculture and Food Technology, Cookstown, County Tyrone BT80 9AA (telephone Cookstown 62491).

Please write or telephone for an application form quoting job reference SB 312/79/NT to the Civil Service Commission, Rosepark House, Upper Newtonards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 12 October 1979.

STATE UNIVERSITY OF NEW YORK

DEPARTMENT OF CHEMISTRY

TENURE TRACK FACULTY POSITIONS

Assistant Professorships in Analytical and Inorganic Chemistry. Applicants for these positions must be committed to excellence in research and teaching. Areas of research should compliment those presently represented in the Department. A complete curriculum vita, which includes a documented summary of past accomplishments and professional references should be submitted to: Chairman, Search Committee, Department of Chemistry, State University of New York at Buffalo, Buffalo, New York 14214. Deadline for applications is January 15, 1980. The State University of New York at Buffalo is an equal opportunity/affirmative action employer. W386(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

tenable for three years and three months from 1 November 1979 to work with Professor B.H. Bransden in the Department of Physics on the Theory of Atomic Charge-Exchange Reaction, with special reference to Heavy Ion Fusion.

Initial salary in the range £4,333 to £7,227 on National Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 19 October 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE from whom further particulars may be obtained. 3276(A)

THE KENNEDY INSTITUTE OF RHEUMATOLOGY

A postgraduate

RESEARCH ASSISTANT

in the

DIVISION OF CELLULAR BIOLOGY

Applications are invited for the post of Research Assistant for six months, for research in cellular biology. The successful applicant will work under the Head of the Division, Dr J. Chayen. An interest in spectroscopy, optics and photography would be helpful.

Depending upon age and experience salary in the range £4,515 to £5,073 (inclusive of London Allowance), based on University of London scales.

Apply by letter enclosing curriculum vitae and the names of two referees, to The General Secretary, Kennedy Institute of Rheumatology, Bute Gardens, Hammersmith, W6 7DW. 3317(A)

Chemists for Drug Research

The Research Institute of Smith Kline & French Laboratories Limited, the UK based research group of the international SmithKline Corporation, is undertaking a planned expansion of its research activities as part of the move to a new 39 acre site in the grounds of a country house – The Frythe – in Welwyn. The new facility, being built to the highest standards of design, represents a major investment and will be totally dedicated to pharmaceutical research and development. Prior to the move to these new laboratories, we are recruiting chemists now as part of the first phase of expansion.

We are particularly interested in hearing from chemists with considerable experience of research in the pharmaceutical industry as well as newly qualified graduates and post-doctorals who wish to embark on a career in industry. This is an opportunity to join a successful basic research group with a broad interest in the biological effects of novel compounds related to specific hormone and transmitter action.

Currently we have the following vacancies:

Synthetic Organic Chemists

Vacancies exist in our Medicinal Chemistry and Chemical Support Departments for synthetic organic chemists, one of whom will be assigned to radiochemistry. Candidates should have a good background in organic chemistry and a flair for practical organic synthesis. Recently qualified candidates should preferably have an honours degree in Chemistry (MRIC, GRIC, B.Sc.) but, alternatively, we would also like to hear from candidates with HND/HNC coupled with relevant experience.

Medicinal Chemist

This post-doctoral vacancy presents an opportunity for a chemist to make a major contribution in synthesising novel biologically active molecules and, in collaboration with biologists and physical organic chemists, in relating biological activity to chemical properties. We invite applications from candidates with up to two years' post-doctoral experience who have demonstrable ability in organic synthesis. Research experience, preferably biologically-orientated and utilising physical-organic principles and techniques, would also be a distinct advantage.

Radiochemist

The radiochemical section has a vacancy for a graduate or Ph.D. to synthesise specifically radiolabelled molecules which may involve devising new routes towards them. Ability in small-scale organic synthesis is essential, and radiochemical training will be given if necessary.

Chromatographic Chemist

A vacancy now exists for a young graduate or equivalent with two to three years' relevant industrial experience to supervise an additional chromatography laboratory which is being set up in our Physical Organic Chemistry Department.

We offer competitive salaries on progressive incremental scales. Newly qualified Honours graduates will start on at least £4,500 and newly qualified Ph.D's at around £6,000. We operate flexible working hours and benefits include free life assurance amounting to three-times annual salary, an excellent contributory pension scheme and a discretionary annual bonus. We also give generous relocation grants to all appropriate candidates.

When replying to advertisement, please indicate which position is being applied for. Please write or telephone Mrs. P. E. Shaw, Personnel Officer – Research.

lications are invited for the post of

POSTDOCTORAL RESEARCH FELLOW

join a multidisciplinary team stigating the aetiology of treatment of cancer. The successful applicant will a key role in the development of this y established group. The post will lve extensive use of cell culture niques and experience in this area is ntial.

lary within the range £5,488 to £7,521 ondon Weighting (under review).

pplications, giving full curriculum and the names and addresses of 2 ees should be sent to the Secretary of Medical School as soon as possible.
3307(A)

UNIVERSITY OF THE WEST INDIES — JAMAICA

Applications are invited for the post of

PROFESSOR/SENIOR LECTURER IN INORGANIC CHEMISTRY, CHEMISTRY DEPARTMENT.

The appointee will be expected to shape and teach undergraduate courses as well as to develop the graduate programme and will be expected to lead in the further development of research in the Department in the field of Inorganic Chemistry. Salary Scales:- Professor 1979/80 J$20,770 to 25714 pa, 1980/81 J$22,848 to 28,284 pa. Senior Lecturer: 1979/80 — J$15,489 to 19,530 pa, 1980/81 — J$17,748 to 21,717 pa (£1 sterling = J$3.00). Family passages; baggage allowance; FSSU.; study and travel grant; unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary is payable.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the UK should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT.

Further details may be obtained from eiher address. 3323(A)

UNIVERSITY OF LEUVEN
Belgium
RESEARCH ASSOCIATE IN VIROLOGY

Applications are invited for the post of Research Associate, tenable for one and preferably two years with extensions possible. The programme is in the broad field of viral hepatitis, including nonA, nonB hepatitis, models of hepatitis-B related hepatoma, and antivirals. It can be expanded to related areas.

Research experience in virology is highly desirable, and proficiency in biochemistry, immunology or electron microscopy would be important assets. Normally only candidates who have passed a doctoral thesis will be considered, and those with postdoctoral experience will be preferred. A working knowledge of English is required.

Commencing salary is equivalent to 18,000-30,000 US dollars per annum, depending upon experience and qualifications. It is indexed to the cost of living, and social provisions including health insurance are as for Belgian nationals.

The position is open immediately. Applicants are invited to submit now their curriculum vitae, list of publications, addresses of two referees and the date from which they would be free to Professor J. Desmyter, Rega Institute for Medical Research, Minderbroedersstraat 10, B-3000 Leuven, Belgium. W387(A)

IMPERIAL CANCER RESEARCH FUND

PROTEIN CHEMISTRY LABORATORIES

SENIOR TECHNICIAN

required by our Protein Chemistry Laboratories to take responsibility for the operation and maintenance of equipment involved in determination of protein structure. Includes Beckman Sequencer, Durrum amino acid analyser and Waters high pressure liquid chromatography apparatus.

HNC/Degree, experience of complex instrumentation desirable. Capability to carry out basic electronic and mechanical maintenance essential. Opportunity to be involved in design and assembly of new equipment.

Salary range £5,370 to £6,939. For further information and application form write or telephone Miss S.M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2. on 242 0200 ext. 305, quoting reference 412/79. 3321(A)

Daresbury Laboratory is developing major national facilities for use by university groups carrying out research in atomic, molecular and biological sciences, nuclear physics and computational science. To provide for the computing needs of scientists working in these fields the Laboratory operates an extensive network of mini-computers, terminals and RJE stations centred on a large IBM 370/165 computer. The recent addition of a CRAY-1 computer has made the installation at Daresbury one of the most powerful in the country, and additional computer staff (male/female) are now sought to cope with the increasing work.

SYSTEM PROGRAMMERS

are required to join a small group engaged in extending and improving the operating systems on IBM, GEC and CRAY computers, where the areas to be strengthened include networking, timesharing, on-line data acquisition and compilers. Successful applicants can expect to work primarily in one or more of these fields, but with ample opportunity to gain experience in almost every aspect of computing. Staff are also encouraged to maintain an interest in the scientific work of the Laboratory.

Previous experience with operating systems is not essential, but a sound knowledge of computing concepts is desirable. The successful candidates will possess a good honours degree in a scientific discipline, a strong and growing general interest in both computers and science and a firm ambition to build a career in scientific computing.

Appointments will be made in the Scientific Officer grade in the salary range £3,289-£5,085 which will increase from 1st January 1980 as follows: £3,591-£5,486.

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

Please write or telephone Warrington 65000 Ext. 467 for an application form quoting reference no DL/704/CB to:

The Personnel Officer
DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

Closing Date: 26th October 1979.

3286(A)

UNIVERSITY OF EDINBURGH
LECTURESHIP IN PHYSIOLOGY
(£4,333 to £8,992)

Applicants must have a good Honours degree in Physiology and at least 3 years' research experience. Further particulars can be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, to whom applications, including a full curriculum vitae and the names and addresses of 3 referees, should be sent not later than 20.10.79. Please quote Reference 1077. 3326(A)

POSTDOCTORAL POSITION — BIOCHEMIST. Available for 2 year appointment to study interrelationships between RNA and cancer. PhD in biochemistry or other related fields with strong background in biochemistry. Salary range $11,000 to $13,000 depending on experience. Submit curriculum vitae and supporting documentation to: Personnel Management Branch, College of Medicine & Dentistry of New Jersey — Rutgers Medical School, PO Box 101, Piscataway, NJ 08854. DEPARTMENT OF AGRICULTURE FOR NORTHERN IRELAND

Senior Scientific Officer/ Higher Scientific Officer/ Scientific Officer
£3,289 to £7,864
(£3,591 to £8,705 from 1 January 1980)

Applications are invited for a pensionable post in the Field Botany Research Division of the Department of Agriculture, situated at the Plant Testing Station, Crossnacreevy, Castlereagh, Belfast.

DUTIES

Duties will involve the supervision of a small team carrying out trials to assess the merit of cultivars of agricultural crops especially grasses and clovers. The successful applicant would in due course be expected to initiate and carry out relevant applied research and to undertake advisory duties. The successful candidate may also be required to undertake lecturing duties in the Faculty of Agriculture and Food Science, Queen's University of Belfast.

Appointment may be at Senior Scientific Officer/Higher Scientific Officer/Scientific Officer level.

QUALIFICATIONS

Senior Scientific Officer

Over 25 years and under 32 years of age on 31 December 1979 with a first or second class honours degree in Agricultural Botany or a closely related discipline and at least 4 years' post graduate experience preferably concerned with the evaluation of crop cultivars. Knowledge of plant genetics and/or biometrics would be an advantage.

Higher Scientific Officer

Under 30 years of age on 31 December 1979 with an honours degree as above and at least 2 years' relevant post-graduate experience.

Scientific Officer

Under 27 years of age on 31 December 1979 with an honours degree as above.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available. (including level of academic attainment and relevant experience) to be best qualified.

SALARY SCALES

Senior Scientific Officer — £5,876 to £7,864. (£6,332 to £8,705 from 1 January 1980)
Higher Scientific Officer — £4,727 to £6,211. (£5,097 to £6,737 from 1 January 1980)
Scientific Officer — £3,289 to £5,085. (£3,591 to £5,486 from 1 January 1980)

There is a non-contributory pension scheme apart from a 1½% deduction from salary to cover widow's and dependants' benefits in the case of male officers.

Please write or telephone for an application form quoting job reference SB 337/79/NT to the Civil Service Commission, Rosepark House, Upper Newtonards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 11 October 1979.

IMPERIAL COLLEGE GRADE 5 TECHNICIAN

Required to work with Dr K.W. Buck and Dr R.H.A. Coutts on cenome organisation and expression of a DNA plant virus. Experience in nucleic acid, protein or virus biochemistry would be an advantage. Salary in the range £3,700 to £4,320 (under review 1.10.79 with further minimum increase of £226 to £264 from 1.4.80). Plus London weighting of £524 (under review). Superannuation, sick pay scheme, 37 and a half hour week. 5 weeks annual leave plus additional days at Christmas and Easter. Modern staff club and excellent facilities, with sports centre, swimming pool.

Application forms can be obtained from: Departmental Superintendent, Biochemistry Department, Imperial College, London SW7. Tel: 01-589 5111 ext. 1119.

3341(A)

SCIENTISTS FOR SAFETY TECHNOLOGY RESEARCH AND DEVELOPMENT

PHYSICISTS AND MATHEMATICIANS

are needed by the

SAFETY AND RELIABILITY DIRECTORATE

of the UKAEA at Culcheth, Warrington,

to work in multi-disciplinary teams on varied technical studies of, and research on the safety and reliability of all types of nuclear reactor systems, and other large scale plants (not necessarily nuclear). Principal objectives are the continual updating of safety and reliability philosophy by anticipating important problems which may arise from technological advances; followed by solutions that can be applied to engineering design and environmental planning. In following these aims there are extensive programmes of collaboration with many overseas countries, and other organisations within the United Kingdom.

Candidates are normally expected to hold honours degrees in relevant subjects, and should have clear interests in advancing safety technology.

Appointments, as SCIENTIFIC OFFICERS, are open to persons of either sex. The current salary range is £3,520 to £5,445 pa, but this is due to be revised to £3,845 to £5,875 from 1.1.80. On the current range a candidate with a first or upper second class honours degree and a year's relevant post-graduate experience could expect a starting salary of £4,285 pa. (£4,870 from 1.1.80.)

Some higher grade posts may be available for people with a few years suitable post-graduate experience.

APPLICATION FORMS and further information obtainable from: Adrian Wilson, The Personnel Officer, UKAEA, SRD, Wigshaw Lane, Culcheth, Warrington WA3 4NE, quoting reference B38/J14.

3287(A)

Wellcome

Biochemist £6000-£7000

The Wellcome Foundation Limited is a major British-owned international pharmaceutical organisation producing a wide range of chemical and pharmaceutical products.

We currently have an opportunity for a biochemist with extensive experience in enzymology to classify the mechanism of action of specified drugs by defining their interactions with enzymes. The successful candidate will work in close liaison with chemists and biochemists and is expected to have a considerable input in the overall design and direction of the work.

Candidates ideally will have skills equivalent to that of a 4 year post-doctoral biochemist/enzymologist and a publication list demonstrating originality in research. The post is at present in the Department of Biochemical Research at Dartford in Kent, which will be relocated in Beckenham in the near future.

We offer a salary in the range £6000 to £7000 depending on age, qualifications and experience. Excellent benefits include 4 weeks' holiday, life assurance and sick pay schemes, excellent sports and social facilities and generous assistance with relocation expenses, where appropriate.

For an application form, please write to or ring
Ian Griffiths, Personnel Officer,
The Wellcome Foundation Limited,
Temple Hill, Dartford, Kent.
Tel: Dartford (32) 23488, ext. 2061.

3333(A)

VIROLOGIST
Assistant Professor

Two-year appointment with the possibility of tenure track. Salary commensurate with experience. To teach 2 half year lecture courses in Virology at the third and fourth year levels plus 1 half year Virology techniques laboratory. The candidate should have a PhD, some post-doctoral experience and be capable of developing a research program in Virology.

Excellent research facilities including Tissue Culture, Radioisotope and Biohazard containment laboratories are available.

The position is to start January 1, 1980, or as soon as a suitable candidate can be found.

Curriculum Vitae with names of 3 referees should be sent not later than December 15, 1979 to:

Chairman,
Department of Biology,
University of New Brunswick,
Fredericton, N.B.,
Canada E3B 5A3

W371(A)

SCOTTISH MARINE BIOLOGICAL ASSOCIATION
DUNSTAFFNAGE MARINE RESEARCH LABORATORY
nr. Oban, Argyll.

Applications are invited for the post of

DEPUTY DIRECTOR

at the Dunstaffnage Marine Research Laboratory.

The Dunstaffnage Laboratory is multidisciplinary, undertaking basic, strategic and applied research in coastal waters and the deep sea. Some postgraduate teaching is undertaken in conjunction with Stirling University. The staff number about 100 and in addition there are about 12 postgraduate students. The Laboratory, which is independent, is funded by a grant from the Natural Environment Research Council and by contract work, and has an annual budget of about £950,000.

Candidates will be expected to have an established reputation in marine science and an aptitude for laboratory administration. The post is graded at Senior Principal Scientific Officer level, and the appointee will be required to take part in the management of the research and administration of the Laboratory and deputise for the Director in his absence.

Application forms and further details may be obtained from the Administrative Officer, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. Closing date for receipt of application forms: 26 October, 1979.

3314(A)

OVERSEAS DEVELOPMENT
KNOW-HOW-vital to developing countries

Oilseeds Agronomist — Tanzania

As member of Oilseeds Research Team carrying out breeding and agronomy projects in Southern Tanzania. Duties:— carry out agronomic investigations on sesame, sunflower and groundnuts in Mtwara, Lindi and Rovuma Regions, assist with regional trials on these crops in substations and villages with particular emphasis on role of the three crops in farming practices and systems of area, train Tanzanian staff in these disciplines and assist in general development of agronomic aspects of Project. Candidates, should possess Honours degrees in Agriculture or Natural Sciences. Appropriate postgraduate qualification and previous overseas experience desirable.

Appointment: 2 tours of 1 year. Salary (UK taxable) in range above £8,000 pa plus a variable tax free overseas allowance in range £1,780 — £4,330 pa (Ref 331X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, stating post concerned, and giving details of age, qualifications and experience to:—

Applications are invited for the following posts in the Unit:

HIGHER RESEARCH SCIENTISTS

POST A – To study the transport and chemistry of radionuclides in the marine environment and to develop models of their dispersion.

POST B – To study the computer simulation of Pressurised Water Reactors dynamic behaviour including the sensitivity and validation of computer models, and to define the systems engineering requirements and supporting experimental programs.

RESEARCH SCIENTISTS

POST C – To study and develop the monitoring of neutron damage fluence in pressurised water reactor materials.

POST D – To study thin-film thermouminescent dosimetry and its application to interface dosimetry.

Appointment will normally be for a fixed period of up to 3 years.

QUALIFICATIONS & EXPERIENCE

Candidates must have First or Upper Second Class Honours degree in a relevant scientific subject (those shortly to qualify may apply). Candidates for Higher Research Scientist posts must also have at least 2 years post graduate experience preferably in the application of simulation or computer modelling in oceanography, in respect of Post A; and simulation and/or modelling in nuclear reactor technology, in respect of Post B.

SALARY

HIGHER RESEARCH SCIENTIST – From £4727-£6211 (to become £5097-£6737 from 1.1.80) } Plus Outer London Weighting

RESEARCH SCIENTIST – From £3289-£5085 (to become £3591-£5486 from 1.1.80) } allowance of £325 per annum

Starting salaries according to qualifications and experience.

The Department has excellent and comprehensive facilities for studies in nuclear technology and the marine environment, with new digital and hybrid computers; a research reactor and analytical laboratories, and has the ability to provide for experiments in the relevant environment to be carried out. There will be opportunities, where appropriate, for successful candidates to register for M.Phil. or Ph.D.(CNAA).

Single accommodation may be available in the College, which provides excellent sports and social facilities.

Request for further details and application forms should be made to:–

The Ministry of Defence, CM(S) 1b3,
Room 310 Savoy Hill House,
Savoy Hill, London WC2R 0BX. Reference 453/01/9

Completed application forms should be returned by 22nd October, 1979.

3308(A)

UNIVERSITY OF FREIBURG/BR

Applications are invited for the post of

POSTDOCTORAL RESEARCH FELLOW IN NEUROCHEMISTRY

to study mechanisms of peptidergic neurotransmission in mammalian brains. Curriculum vitae and references should be sent to:

Dr H. Cramer, Professor, Section on Neurochemistry, Department of Neurology, Hansastr. 9, D-7800 Freiburg, West Germany. W388(A)

Laboratory Scientific Officer required as soon as possible until 31st January 1981 for work in the field of histology and spectrophotometric analysis, in the Dental Clinical Research Laboratory. Salary for qualified Laboratory Scientific Officer not less than £3,788 (revising to £4,125 on 1st January 1980) plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. D.C.R. 3311(A)

UNIVERSITY COLLEGE CORK

BIOCHEMISTRY

Applications are invited for two research positions supported by grants from the National Board for Science and Technology. Applicants should have an honours degree in Biochemistry or Chemistry and preferably a higher degree.

The appointments are for one year in the first instance with the probability of extension for one or two further years. Salary will be in accordance with qualifications and experience.

Applications, including a curriculum vitae and the names of two referees should be sent to Professor Shawn Doonan, Department of Biochemistry, University College, Cork, Lee Maltings, Prospect Row, Cork. (Ireland). **3334(A)**

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of

RESEARCH FELLOW

in the Department of Biochemistry. The project, under the supervision of Dr S.B. Brown and supported by the Nuffield Foundation, will involve studies on the mechanisms of oxidative degradation of haem and chlorophyll derivatives. The post will be suitable either for an organic chemist interested in acquiring experience in a biochemical environment or, alternatively, for a biochemist with some competence in organic chemical techniques. Previous experience with tetrapyrroles would be an advantage but is not essential. A PhD degree is required. The appointment will be made for a fixed period of three years and it is hoped that the successful candidate will be able to take up the post as soon as possible.

Starting salary in the range £4,333 to £5,488 on the 1A scale for Research and Analogous Staff (£4,333 to £7,521) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/25. Closing date for applications 19 October 1979.

3319(A)

The European Space Agency has the following vacancies in the Space Science Department at its Technological Centre in Noordwijk, The Netherlands:

scientists european x-ray observatory satellite exosat operations

Applications are invited from young scientists holding post-doctoral or equivalent qualifications in astronomy or physics and having experience with scientific instrumentation and data analysis (preferably related to space research) to act as duty scientists in the operation of the European X-Ray Observatory Satellite EXOSAT.

Duties include evaluation of the feasibility of observation proposals, establishment of observation programmes, liaison with observers, conduct of observations and preliminary data analysis. The scientists will have the opportunity of undertaking their own observation programmes in X-ray astronomy.

Prior to launch the scientists will be located at ESA's Space Science Department ESTEC, transferring to ESOC, Darmstadt for orbital operations.

Application forms and further details may be obtained from the Head of Personnel ESA/ESTEC, Noordwijk, The Netherlands.

W395(A)

IMPERIAL CANCER RESEARCH FUND

MEDICAL ONCOLOGY UNIT

at St. Bartholomew's Hospital

TECHNICIAN/ RESEARCH OFFICER

required by our Medical Oncolog Unit at St. Bartholomew's Hospita to continue the investigations of non Hodgkin Lymphoma by surfac marking techniques.

HNC/Degree with experience o immunology (immunofluorescenc rosetting techniques, complemen technology or tissue typing) essentia Salary range £4,122 to £5,949.

For further information and appli cation form write or telephone Mis S.M. Hurley, Imperial Cance Research Fund, Lincoln's Inn Field London, W.C.2. on 242 0200 ex 305, quoting reference 410/79.

3320(A)

THE UNIVERSITY OF MANCHESTER

BARKER CHAIR OF CRYPTOGAMIC BOTANY

Applications are invited for the Bark Chair of Cryptogamic Botany which w fall vacant on October 1st, 1980 followi the retirement of Professor John Colhou The University has a preference f candidates with interests in the appli fields. The other Chair in Botany is t George Harrison Chair to whic Dr Elizabeth G Cutter has been elect Particulars of the appointment may obtained from the Registrar.

Applications (2 copies, 1 suitable f photocopying), giving full details qualifications, experience, research et and the names and addresses of thr persons to whom reference may be mad should be sent to The Registrar, T University, Manchester, M13 9PL October 10th. 3159(A)

UNIVERSITY OF DUBLIN
Trinity College

and

GEOLOGICAL SURVEY OF IRELAND

MICROPALAEONTOLOGIST

A micropalaeontologist or palynologis with a minimum of three year postgraduate experience is required t work on contract for the Geologica Survey of Ireland. The successfu candidate will head a joint Geologica Survey/Trinity College Dublin tea making an integrated stratigraphica study of offshore Mesozoic basin based upon material obtained fro petroleum exploration wells.

The post, which will becom available in January, 1980, carries commencing salary of £7,000 p.a.

Further particulars are obtainab from

Professor C.H. Holland,
Department of Geology,
Museum Building, Trinity Colleg
Dublin 2,

to whom applications, including th names of three referees, should be se *not later than 30th October, 1979.*

3329(A)

ICI CORPORATE LABORATORY, RUNCORN

MOLECULAR BIOLOGIST

Applications are invited from molecular biologists with a minimum of two years' post-doctoral experience to join a research team interested in the control of expression of eukaryotic genes. Experience in the isolation of MRNA from mammalian tissue and techniques of DNA cloning are highly desirable.

The appointment will be on a permanent basis and the work will be situated in our laboratories at Runcorn where a GMAG approved category III laboratory is available. In addition, there will be opportunity to collaborate with the group working in the ICI Joint Laboratory in the Biochemistry Department at the University of Leicester.

Excellent career prospects exist and, in addition to a competitive salary, the Company has a profit sharing scheme and an excellent contributory pension scheme. Where appropriate, assistance will be given with relocation expenses.

Applicants should write, enclosing full curriculum vitae, to:—

Miss S E Bird
Personnel Officer
ICI Corporate Laboratory
P O Box 11 The Heath, RUNCORN
Cheshire

SEMINARS and SYMPOSIA

CHROMATOGRAPHY DISCUSSION GROUP
(LC sub-group)

One-day Symposium at Hatfield Lodge Hotel, Hertfordshire on November 29th, 1979.

BIOMEDICAL APPLICATIONS OF HPLC

Lecture programme and speakers:—

Drug and metabolite analysis in biological samples
  Mr G Merry (Waters)
Measurement of vitamin D metabolites in serum
  Mr T Clemens (Middlesex Hospital)
Drug metabolism studies using HPLC
  Dr T R Marten (Roche Products Ltd)
Determination of Ranitidine and its metabolites in body fluids
  Mr P Carey (Glaxo Group Res.)
Nucleoside and nucleotide analysis using reversed phase HPLC
  Dr R Hartwick (University of Edinburgh)
Theory of Isotachophoresis and its application to Biomedicine
  Mr J Heslop (LKB)
An automated system for pre chromatographic clean up of biological samples
  Dr G B Cox (Du Pont)

Symposium fee £12.50, non-members £17.50.

Application forms from Mrs J A Challis (Exec. Sec. CDG)
Trent Polytechnic, Burton Street,
Nottingham NG1 4BU
Tel. 0602-48248 Ext 2187

3294(M)

UCLA JERRY LEWIS NEUROMUSCULAR RESEARCH CENTER'S
Inaugural Symposium on Excitation-contraction coupling

will be held December 4-7, 1979, at UCLA. Topics for discussion: Electrophysiological Analysis of EC Coupling; Mechanisms at the Level of the T-SR Junction; Molecular Aspects of the Contractile Response.

For program and registration information, write: Alan D. Grinnell, PhD, Director Jerry Lewis Neuromuscular Research Center, UCLA School of Medicine, Los Angeles, California 90024.

W392(M)

FELLOWSHIPS

UNIVERSITY OF SOUTHAMPTON

SCHOOL OF BIOCHEMICAL and PHYSIOLOGICAL SCIENCES
BIOCHEMISTRY DEPARTMENT

POSTDOCTORAL RESEARCH FELLOW — BIOCHEMISTRY

Applications are invited for a Postdoctoral Fellowship in Biochemistry. This appointment is a MRC funded position, available for a postdoctoral biochemist to work in collaboration with Dr D P Bloxham on the development of techniques for the measurement of rates of hepatic glucose and glycogen metabolism. The position will be well suited to candidates with a research background in enzymology who wish to expand their interest in metabolic control. The appointment is for one year in the first instance, commencing as soon as possible, with the possibility of an extension for a further two years.

Starting salary £4,333 pa (under review wef 1 Oct 79) on Range 1A. USS benefits.

Applications giving date of birth, curriculum vitae and the names of three referees should be sent to Mrs P Vaughan-Smith, The University, Southampton, SO9 5NH by 15th October 1979. Please quote reference 1098/R/N. 3281(E)

-Unique Opportunity-

STANFORD UNIVERSITY
NSF POSTDOCTORAL FELLOWSHIP in MOLECULAR BIOLOGY and COMPUTER SCIENCE
$14,000 per annum

Applicants should be familiar with the techniques of modern molecular biology and be interested in entering the field of computer science. Previous programming experience is useful but not essential. Responsibilities will include development and maintenance of a knowledge base of current laboratory techniques for use with an advanced model of automated experimental planning. One goal of this program is to train an individual for a career in computer science as applied to molecular biology and genetics. While the fellowship will be awarded through the Department of Computer Science, the fellow will interact regularly with research groups in the Departments of Biochemistry and Medicine.

Send resume and the names of three references to either:
Dr Douglas Brutlag, Department of Biochemistry or Dr L.H. Kedes, Department of Medicine, Stanford University, School of Medicine, Stanford, California 94305. Equal opportunity through affirmative action. W383(E)

IMPERIAL CANCER RESEARCH FUND

RESEARCH FELLOWSHIP

A post doctoral fellow is sought to join a group working on the structure and function of paporavirus tumour antigens, with particular emphasis on the possible role of membrane associated protein kinases in virus induced transformation. Experience in cell biology, membrane biochemistry, protein kinases or enzyme purification might be advantageous.

Three year appointment. Salary range £5,800 to £7,100. Further information from Dr Alan E. Smith (01 242 0200 ext. 239). Applications with curriculum vitae and the names of two referees should be sent to the Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2. quoting reference 394/79.

3225(E)

PORTSMOUTH POLYTECHNIC

BIOPHYSICS LABORATORIES

POST-DOCTORAL FELLOWSHIP in CHROMATIN RESEARCH

An SRC supported position is available until September 1981. The subject of study is the post-synthetic acetylation of histones, a chemical modification important in the control of genetic activity. The project is part of a large team effort devoted to the structure and function of chromatin. Candidates need not have experience in chromatin research but would be expected to have completed doctoral studies on a biochemical topic.

Salary: £4,722 to £4,845 per annum, plus an interim supplement at the rate of £72 per annum.

Application forms and further particulars from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, to whom completed applications should be returned by 11th October 1979.

Please quote reference no: S96.

3297(E)

RESEARCH FELLOWSHIP

A post-doctoral cytogeneticist or molecular biologist, with experience in human karyotyping, is required to participate in a project on the analysis of chromosomes from human solid tumours.

The appointment is for three years. Salary with entry according to qualifications and experience within range £5,990 to £7,434 inc. L.A. For further information telephone Dr E. Solomon 242 0200 extension 426.

Applications with curriculum vitae and names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2., quoting reference 407/79. 3273(E)

NEW HALL, CAMBRIDGE
RESEARCH FELLOWSHIP

Applications are invited from graduates for a Research Fellowship in Science, tenable at New Hall for three years from 1st October 1980.

Application forms and further particulars may be obtained from the President, New Hall, Cambridge, CB3 0DF, to whom applications should be sent by 1st November 1979. 3338(E)

FELLOWSHIPS continued

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

RESEARCH FELLOWSHIP

A Research Fellow is required immediately for the period to 31 October 1980 for work supported by the Medical Research Council on hepatic glucokinase. The Fellow will work with Professor D G Walker and continue a project concerned with several aspects of the metabolic regulation of the enzyme.

Salary on scale starting at £4,333 (October scales) according to age and experience, plus USS: maximum starting salary £6,066.

Applications as soon as possible to Miss L R Heyes, Senate Registry, University of Birmingham, PO Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. 3331(E)

UNIVERSITY OF FREIBURG/BR

Applications are invited for a

POSTDOCTORAL FELLOWSHIP IN NEUROBIOLOGY

for research in pharmacology of neuroendocrine functions in sleep.

Curriculum vitae and references should be sent to: Dr. H. Cramer, Professor, Section on Neurochemistry, Department of Neurology, University of Freiburg, Hansastr. 9. D-7800 Freiburg/Br., West Germany. W389(E)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH FELLOW

Applications are invited for a research fellowship financed by an industrial company for a study of dietary phospholipids and liver lipid metabolism in relation to heart disease. The fellowship is tenable initially for one year from 1st October, 1979 or a date to be agreed. Renewal for a further two or three years is possible. Initial salary £4,333 with membership of U.S.S.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to Professor J.N. Hawthorne, Department of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Nottingham NG7 2UH from whom further details may be obtained (telephone 0602-700111, Ext. 3488). 3235(E)

FRIEDRICH MIESCHER-INSTITUT

POSTDOCTORAL FELLOWSHIP

IN BIOCHEMISTRY

is available for the area of ß-adrenergic receptor-mediated effects in tissue culture cells. The fellowship will run for two to three years.

Candidates should send c.v. and three names of referees to Dr M. Staehelin, Friedrich Miescher-Institut, PO Box 273, CH-4002 Basel, Switzerland. W364(E)

UNIVERSITY OF LONDON

THE SCHOOL OF PHARMACY

POST-DOCTORAL RESEARCH FELLOWSHIP IN RETINAL PHARMACOLOGY

Applications are invited for a research fellowship, funded by the S.R.C. to study transmitter substances in the vertebrate retina. The appointment is for three years from 1st November 1979 or later.

Applications, stating age, academic qualifications, research experience and the names of two referees should be submitted to:— Dr M. J. Neal, Department of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, from whom further particulars may be obtained. 3340(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for an MRC-financed Postdoctoral

RESEARCH FELLOWSHIP

to work with Dr Ian P. Trayer on the role of myosin light chains in actomyosin interaction. The successful applicant will join a group investigating different aspects of the actomyosin interaction using a variety of chemical and physical techniques. The post is tenable from 1 October 1979, and is funded for three years. Starting salary will be between the points £4,333 and £4,910 (plus USS) on the Research Fellow 1A scale, depending on age and experience.

Further details can be obtained from Miss L R Heyes, Senate Registry, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (2 copies), together with curriculum vitae and names of 2 referees, should be returned not later than 15 October, 1979. 3330(E)

SENIOR VISITING FELLOWSHIP PROGRAM

Centre for Interdisciplinary Studies in Chemical Physics
The University of Western Ontario
London Ontario, Canada N6A 3K7

The Centre for Chemical Physics at The University of Western Ontario invites applications for its Senior Visiting Fellowship Program from established scientists working in areas that bridge two or more of the disciplines of applied mathematics, physics, chemistry, engineering, botany, biophysics nuclear medicine and radiation oncology. The Fellowships are tenable for a period of up to 12 months, and provide funds for travel, partial or complete living support at U.W.O., and some research support. During the tenure of their Fellowships, visitors will be expected to work in conjunction with Centre members.

Interested persons are asked to write to:

The Chairman, Visiting Fellows Committee,
Centre for Inter-disciplinary Studies in
Chemical Physics,
The University of Ontario,
London, Ontario, Canada N6A 3K7

for application forms and additional information. Applications for 1980/81 must be received no later than November 1, 1979. W385(E)

McMASTER UNIVERSITY

DEPARTMENT OF BIOCHEMISTRY

A POSTDOCTORAL FELLOWSHIP

is available in the area of mitochondrial biogenesis in mammalian cells with emphasis on genetics, proteins biosynthesis and membranes, with Dr K.B. Freeman.

The fellowship is valued at $12,200 per year, taxable and may be renewed for one year. For further information write to: Dr K.B. Freeman, Department of Biochemistry, McMaster University, 1200 Main Street West, Hamilton, Ontario L8S 4J9 Canada. W396(E)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF ANATOMY

Applications are invited for a

DEPARTMENTAL STUDENTSHIP,

tenable for one year in the first instance and renewable up to a maximum of four years, to work either on morphological aspects of developmental neurobiology or on muscle structure. The successful candidate will be expected to register for a higher degree and to undertake a limited amount of teaching.

Salary £1,820; fees paid by University.

Further details may be obtained from Professor E.J. Clegg, Department of Anatomy, Marischal College, Aberdeen AB9 1AS, to whom applications, accompanied by the names of two referees should be sent by Friday, 26th October, 1979. 3336(E)

The ISAAK WALTON KILLAM POSTDOCTORAL FELLOWSHIPS

1980-81

DALEHOUSIE UNIVERSITY

Value
Fellowships valued at $13,500 (1979-80), plus travel allowances, are tenable for one year at Dalhousie University in most fields of study. Application for extensions may be considered.

Qualification
applicants should have recently completed a PhD Degree at a recognized university, or expect to obtain a degree before taking up an award.

Application
Application forms may be obtained by writing to:

The Office of the Dean, Faculty of Graduate Studies, Dalhousie University, Halifax, Nova Scotia B3H 4H6

The closing date for receipt of applications is 15 December, 1979. W382(E)

UNIVERSITY OF EXETER

DEPARTMENT OF CHEMISTRY

RESEARCH STUDENTSHIP

Applications are invited for an SRC CASE Research Studentship with the British Gas Corporation to carry out studies on the phase equilibria and thermodynamics of binary and multicomponent mixtures at high pressures.

Applications, together with the names of two referees, should be sent to Dr K Stead, Department of Chemistry, University of Exeter, Exeter, EX4 4QD. 3327(E)

ASSISTANTSHIPS

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

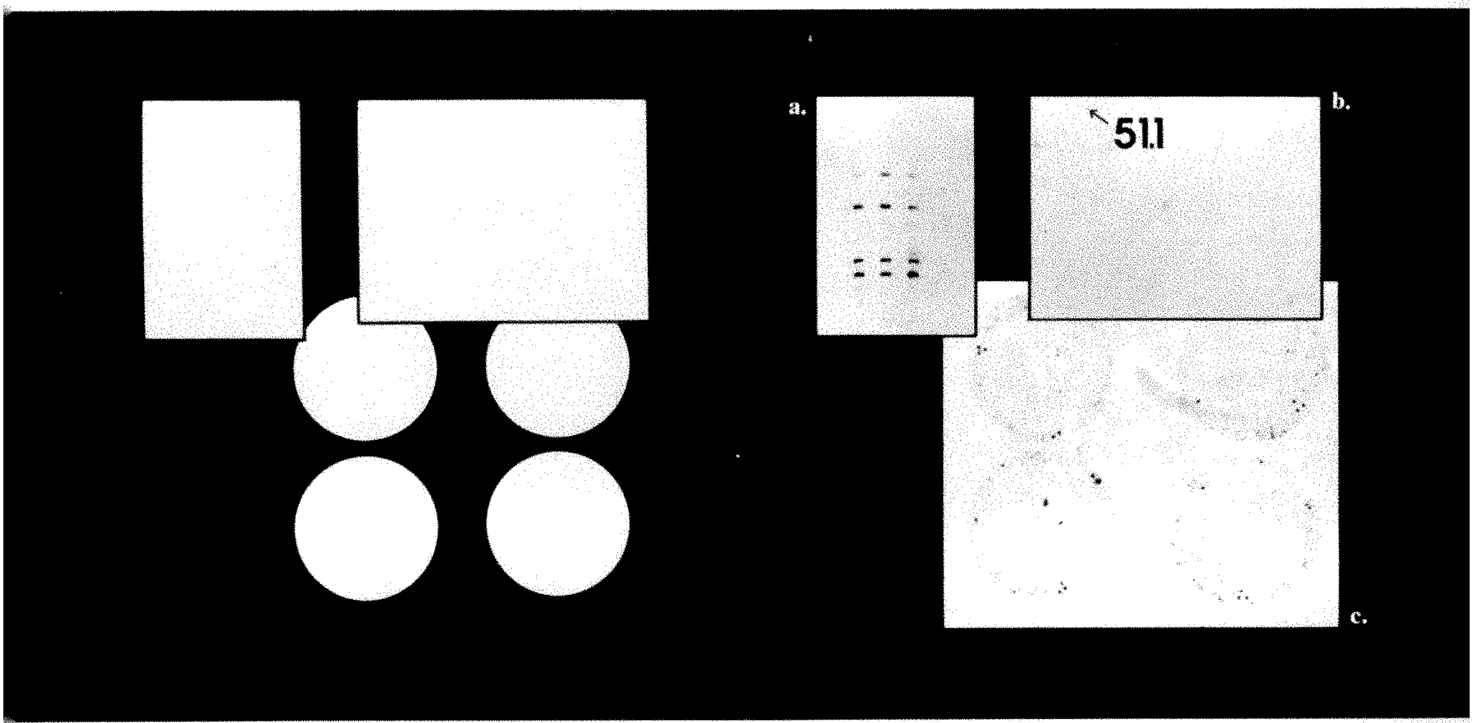
You need BA 85 nitrocellulose to get the picture.



S&S BA 85 pure nitrocellulose.

Autoradiograms (unretouched, approx. ⅙ actual size).

Shown at the top right are unretouched photographs of background-free autoradiograms of labeled RNA or DNA hybridized to single-stranded DNA. They were developed from "Southern" blots and "plaque lifts" using Schleicher & Schuell BA 85 nitrocellulose.

They really make the case for S&S BA 85.

BA 85 succeeds so well because it's *pure* nitrocellulose. This means you get maximum transfer of DNA from gels or plaque lawns. The smaller fragments are not lost. And you're assured of a more complete hybridization with RNA or DNA probes.

For these reasons, S&S BA 85 has become the standard for hybridization studies. When nucleic acid investigators specify "nitrocellulose" they really *mean* pure nitrocellulose—S&S BA 85.

BA 85 is available plain or gridded. And in circles, rolls, squares, strips and full sheets. What more could you ask for? Ask us.

If you're not already using BA 85, you owe it to yourself to try some. Write to S&S on your letterhead and we'll send you a sample in the size you request (up to 15 cm square or 82 mm diameter). Also, S&S has a newsletter on DNA/RNA applications, procedures and products. It's called "Sequences". Ask to be put on the mailing list.

---

a. DNA fragments which hybridize with a probe that is homologous to nitrogen fixation (*nif*) genes of *Klebsiella pneumoniae*. Prepared by Gerard Riedel, The Biological Laboratories, Harvard University.

b. Screens of mouse and human shotgun collections (approx. 25% of original autoradiogram). Prepared by the Blattner and Smithies groups, Laboratory of Genetics, University of Wisconsin. Technique described in the following papers: 1) Blattner, F. R. *et al.* 1978. Science. 202:1279-1284; 2) Smithies, O. *et al.* 1978. Science. 202:1284-1289.

c. Genome screening of a sea urchin library cloned in Charon 4λ bacteriophage. Prepared by D. M Anderson, R. H. Scheller and J. W. Posakony, Division of Biology, California Institute of Technology.

Detailed descriptions of autoradiograms available on request from S&S.

IMMUNOCHEMICALS FROM MILES?

YES, INNOVATIVE AND PROVEN PRODUCTS FOR RESEARCH AND CLINICAL LABORATORY USE.

Perhaps you think of Miles as a place to get the unusual, like antiserum to rat IgE or equine IgM.

Perhaps you know we offer a wide selection of human protein antisera encompassing newer products, such as antisera to myoglobin, ferritin and β-2 microglobulin, as well as established antisera to immunoglobulins, α-1 antitrypsin and other major serum proteins.

Of course, you may not associate us with immunochemicals at all... We think you should.

BP Energy Research Prize

AN INTERNATIONAL AWARDS SCHEME OPEN TO TEAMS AND INDIVIDUALS FROM UNIVERSITIES AND OTHER INSTITUTES OF HIGHER EDUCATION.

As part of its involvement in energy and conservation, BP has established the BP Energy Research Prize.

The aim of the Awards Scheme, is to provide a further stimulus to the development of new ideas concerned with energy conservation and the better utilisation of energy resources.

In the UK, awards to support research programmes and prizes totalling £50,000 will be made available.

The winning project will be the UK entry for the BP International Energy Research Prize.

Judging

Provided by the Royal Society in association with the Fellowship of Engineering.

UK Awards

Three awards, each of £10,000 to support three selected research projects for one year. The winning project will receive a prize of £5,000 plus £10,000 towards a further year's research.

International Prizes

An international competition open to research projects nominated by BP associate companies overseas.

The first prize will be £10,000.

Full details and entry forms obtainable from: BP Energy Research Prize, Britannic House, Moor Lane, London EC2Y 9BU.

Closing date for receipt of completed entry forms is 10th December, 1979.

Culturing cells?

Would you like a cell culture technique which gives you higher cell yields for less effort, less time and less money?

You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 – the new dimension in cell culture.

Ask for more information today, and prove it for yourself.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Job-swapping could relieve academic stagnation

ACADEMICS in mid-career might consider exchanging posts for a period of up to five years. Those who scan the classified advertisement columns every week are only too aware that jobs for scientists in British universities are very scarce at present. As a result of low levels of retirement, disappointing recruitment of students into the sciences, and continued financial stringency which makes every new appointment subject to the closest scrutiny, there are no more academic jobs on the market in the late 1970s than there were in the early 1960s, before the great university expansion.

The plight of those at the bottom of the academic ladder has been well publicised over the past year or two — they are finding that if they are lucky they can subsist for a few years on postdoctoral fellowships before obtaining a permanent post, but without such fortune even highly capable young people may simply have to give up any aspirations to an academic career.

Less well publicised is the problem of the person in mid-career. Remarkably few academic positions are advertised at this level, because remarkably few academics are at present vacating their posts because remarkably few academic positions are advertised because . . . . Those jobs that are freed because their holders move to professorships are largely filled internally because almost every department is experiencing heavy pressure for promotion in the ranks. The result, as is well known, is stagnation as everyone holds tight to the job they have. And stagnation ultimately leads to demoralisation.

Dr Colin Clarke, of the School of Biological Sciences in the University of East Anglia puts forward a simple proposal. He writes:— "A simple, admittedly imperfect and partial solution to this problem would be that of direct academic exchange. Thus a lecturer in, say, genetics in University A might exchange his position, and possibly his house, with a similar person in University, or even Research Institute, B with great potential advantage and stimulation to both individuals involved and their departments. At its simplest this scheme could be largely informal and need not involve more expenditure than that of mutual visits and removal costs. House exchange, rather than house purchase, might avoid further financial problems. I suggest that for both academic and family reasons there would need to be a minimum period for such exchange, of perhaps 3 or 5 years. A permanent, or longer term, exchange could then follow, but only if both partners and both departments were satisfied with the arrangement.

"This scheme has the advantage that it allows for the exchange of people whose scientific interests are not exactly matched, in some cases to the clear advantage of particular pairs of individuals or departments. Thus someone working in, let us say, applied plant genetics might exchange with another person whose interests are recombination in bacteria, depending on the existing interests and staffing of the two departments involved.

"The above scheme might operate via a personal advertisements section in *Nature*. Below is a sample advertisement, of the type envisaged, which I have written for myself. There will, of course, be objections to this scheme, not least perhaps from universities if the persons contemplating exchange are not on identical salaries. The present national academic situation is, however, so stagnant that solutions of the above type are highly desirable and their advantages to individuals and departments far outweigh administrative objections.

EXCHANGE SOUGHT

Reader in Microbiology, University of East Anglia, Norwich, research interests in Microbial Mutagenesis and Bacterial Morphogenesis, general interests in many aspects of General Microbiology and Microbial Genetics. Extensive teaching experience mainly Microbiology and Genetics. Exchange over 5-year, or longer, period for Sept 1982 onwards with like person in University or Research Institute, perhaps in Midlands or Scotland. Please contact Dr Colin Clarke, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ (Phone 0603-56161, extn. 2232). It may be possible to arrange a housing exchange involving 4-bedroom, detached house with garage and gas c.h. in Norwich.

Would it work? Dr Clarke will be able to tell us fairly soon. The record of the civil service, which tried out a similar mobility scheme a few years ago, is no encouragement. Interest in temporary exchanges was insufficient to warrant continuing the scheme after a year or two. But maybe academics are different. And maybe there is a growing awareness of the importance of sideways moves. If so, then *Nature* will be glad to support such a scheme. □

Carter faces new dilemmas over non-proliferation

In the last of three articles about US attempts to regulate the social effects of science and technology, **David Dickson** describes the problems raised by President Carter's policy for controlling the spread of nuclear weapons

ONE of the main issues in the US presidential elections next year — just as it was when Jimmy Carter faced Gerald Ford three years ago — is likely to be whether the US should revise its attitude towards the relationship between the spread of nuclear energy and the proliferation of nuclear weapons.

Three years ago Carter gained considerable political capital from his firm stand against both the reprocessing of spent fuel and the development of fast breeder reactors, arguing that if not properly controlled, both could increase the risks of nuclear weapons proliferation — by encouraging production of weapons-usable plutonium. A week before the election he castigated President Ford's initiatives in the same direction as "too little and too late".

Now it is President Carter's own policies that are on trial. In particular attention has focussed on the results of the Nuclear Non-Proliferation Act (NNPA) passed overwhelmingly by Congress last year, and whether the strategy embodied in this act — attempting to control weapons proliferation through abrogation of commercial reprocessing and unilateral restrictions on uranium supply — remains the most appropriate direction to take.

Some argue that the apparent failure of the US to achieve a significant consensus in support of this strategy at the international level indicates inherent flaws. They point in particular to the provisional conclusions of the International Nuclear Fuel Cycle Evaluation (INFCE), set up at Carter's suggestion in 1977 and due to report formally next February, which are expected to give little support for the US strategy.

Others argue, conversely, that the administration has not been strict enough in applying its restrictions. "Many of us feel that there has been a great deal of back-tracking by the administration, and that this seems to be accelerating rather than slowing down" said one Congressional aide last week, pointing for example to delays in implementing certain aspects of the act and the administration's apparent leniency in accepting conditions for the retransfer of spent nuclear fuels for reprocessing.

Three aspects of the proliferation issue are likely ot rekindle a public debate which has been relatively dormant since the signing of the NNPA last spring. The first is the failure of the US, despite cutting off economic and military aid, to dissuade Pakistan from what many believe to be its current attempts to develop nuclear weapons. "If Pakistan does explode a nuclear device, then it could have the same galvanising effect as Three Mile Island did," predicts one observer.

The second aspect is the growing economic crisis of the US nuclear power industry. At present the industry is still meeting past orders; but domestic orders have virtually dried up, and export orders may be the only way to keep the industry alive. But these are now seriously hampered by US non-proliferation policy.

The third factor affecting the debate will be the occurence of a number of international events focussing on the proliferation issue, including the domestic debate on a comprehensive test ban treaty (hopefully agreed in draft form by the US, USSR and UK in the near future), the review of the Non-Proliferation Treaty signed in 1970, and the outcome to the INFCE discussions.

INFCE: technical or economic?

Despite a relative lack of support for the thesis that the threat of proliferation requires of itself a reduced commitment to reprocessing and fast breeders (even though this may result *de facto* from technical and economic problems), US officials claim that the INFCE exercise has been a success in getting the link between plutonium production and the threat of proliferation firmly on the international agenda.

"INFCE has accomplished the largest part of what it was meant to do. As well as making a number of specific suggestions on way to go forward, it has been a process of international education, and despite difference between individual countries, there has been a considerable convergence over the past two years", says Dr Nye, one of the chief architects of the act and now Professor of Government at Harvard University.

However INFCE is unlikely to result in any major international shift towards the position so firmly enunciated by President Carter three years ago. (Indeed some suggest that the study may have been partly arranged to get the President off the hook). And despite the US administration's insistence that it was always intended as a technical exercise, and not a negotiating forum, scepticism of the US stance is based on the concern that technical exercises have been used as a front for political and economic interests.

Many European countries, for example, have accused the US of using its anti-reprocessing stand as a means of exploiting its market potential as a major supplier of enriched uranium, and of making up for its lack of progress in fast breeder design.

Political distrust also lies behind the rejection of US non-proliferation policies by Third World countries such as India and Pakistan. These countries see attempts by the US to prevent their access to nuclear technology, on any grounds, as an illegitimate infringement of sovereignty.

Domestically US politicians show little embarrassment for arguing that the US should use its position of nuclear hegemony to both articulate and justify its strategy on proliferation policy. "Unfortunately, certain countries have refused to see the wisdom of our position. If this situation persists, they may force the US to discontinue further nuclear collaboration," Representative Jonathan Bingham, one of the staunchest supporters of the NNPA, said recently.

At the same time, administration officials are increasingly concerned that the US position on non-proliferation strategy may be undermining the US's hegemony on nuclear issues in favour of various European countries — and that this could have wide economic and political implications.

Last week, for example, the Senate rejected a motion to discontinue research on the liquid metal fast breeder reactor at Clinch River in Tennesee (a long-time target of President Carter's). The main arguments for rejection were couched no so much in terms of its technical and economic appropriateness, severely questioned by the administration, but on the argument that the US is several years behind Europe in fast reactor design, and that this alone was sufficient reason for pressing ahead with the project.

Given the distrust that exists both in Europe and in the Third World over the political implications of the US non-proliferation strategy, one of the few statements that can be made with certainty is that international consensus is still a long way off — and that reaching such a consensus will be one of the major diplomatic tasks of the 1980s.

One major source of contention during the INFCE discussions, for example, has been on reaching agreement on the extent of global uranium supplies. Those opposed to the urgent need for reprocessing have argued, in support of their position, that global supplies are plentiful; those supporting both reprocessing and fast breeders support a much lower estimate, adding weight to their position.

The resulting assessment of supplies is likely to be an ambiguous compromise between these two positions, with a range of possible estimates. "The vocabulary may be largely technical, but the messages and stakes are highly political, and as such INFCE presents a fascinating case study in the interaction of science and politics,"

0028-0836/79/400328-02$01.00

Canisters of uranium-238 stockpiled at Paducah, Kentucky — the 'spent fuel' that can be converted to plutonium in a fast breeder

commented Peter Clausen of the Department of Energy's Office of Energy Research in a recent issue of *Arms Control Today*.

Domestically, the provisions of the Nuclear Non-Proliferation Act have placed new demands on the agencies required to see that they are carried out — in particular the Department of State, the Department of Energy, and the Nuclear Regulatory Commission.

The State Department, for example, has had to bear the brunt of external criticism of the administration's policies, particularly from countries with which it is actively seeking cooperation in other spheres; some critics claim that this has tempted the department to make compromises in carrying out its role — for example, in allowing reprocessing for the purposes of breeder research — that go considerably beyond Congress' original intentions.

The role of the Department of Energy, long an ally of the very industry which has been most affected by the NNPA, has also come under fire, critics claiming a conflict of interest between its functions of promoter and regulator of enriched uranium exports.

Finally several members of the Nuclear Regulatory Commission have expressed public disquiet about being asked to judge the adequacy of safeguards in countries which made requests for enriched uranium. This required the commission to play a direct foreign policy role for which it is ill-equipped.

"It is a major foreign policy action for an agency of the United States Government to go to a foreign country and say: we must inspect your facilities, we must inspect your system, before we will grant an export license. The NRC staff are not foreign policy experts," Commissioner John F Ahearne said in an address "Does the Emperor Have any Clothes?" given in New Orleans three weeks ago.

Government agencies, however, are not the only ones having difficulty with grappling with the issues thrown up by the debate proliferation. There are also deep differences in strategy among environmental groups concerned with the dangers of nuclear power in all its forms.

Some argue that the prime need is to define the technical parameters of the licensing process in a way that minimises the environmental impact of nuclear power. "We have tried to get political considerations out of export licensing," says Jacob Scherr of the Natural Resources Defense Council (NRDC), arguing against Commissioner Ahearne that it is possible to define criteria for the adequacy of safeguards that are "technical and objective".

Others, however, argue the case against nuclear technology on the more explicitly political grounds of opposition to the social and economic interests which it supports. "The NNPA is more a mechanism for sharing the nuclear market than an attempt to curtain nuclear weapons in the developing countries; certainly it is looked upon by these countries very cynically as a market control mechanism," says Bob Alvarez of the Environmental Policy Centre (EPC).

Such different perspectives can lead to a considerable divergence in policy. A particular case is over whether or not the US should fulfil its commitment to provide storage facilities for fuel which has been used on foreign reactors. Groups such as the NRDC argue with the administration that providing such storage, coupled with a guarantee of providing enriched uranium fuels, will take the pressure off the need for reprocessing facilities in foreign countries — and hence help reduce the chances of weapons proliferation.

In contrast, EPC and other nuclear groups argue that the US's provision of storage facilities would not only present a potential hazard to the US environment, but would also help encourage the spread of nuclear energy by getting other countries off the hook on the question of waste disposal. "Our philosophy is more concerned with restricting the spread of nuclear technology itself, rather than using a safeguard approach based on restricting the supply of nuclear materials," says Dr David Berrick of EPC.

Somewhat less predictably, the proliferation issue has also recently raised some difficult constitutional questions. These result from the recent publication of an article giving scientific and technical details of the construction of the hydrogen bomb, all claimed to be derived from public, non-classified information.

Finally there is the thorny question of how to deal with the Non-Proliferation Treaty when it comes up for review next year. At one level there is the question of the extent to which recent moves by the nuclear countries to restrict the export of "sensitive technologies" contravene Title IV of the NPT, which promises "the fullest possible exchange of equipment, materials and scientific and technological information for the peaceful uses of nuclear energy."

Perhaps more fundamental is the fact that,as it currently stands, the treaty codifies an inherent inequality between weapons states and non-weapons states. This condition that may have appeared appropriate when the treaty was negotiated in the late 1960s; but it fits uneasily with the demands made for a new international economic order, implying a form of North-South hegemony which many countries have demonstrated their unwillingness to accept by refusing to sign the treaty.

In the short-term, the Carter administration is now faced with the prospect of Pakistan exploding a nuclear device, and thus joining the "nuclear club" within the relatively near future. A state department study group was set up under the direction of Mr Smith late in August to discuss possible strategies by the US to prevent this, given that its current attempts to apply pressure through sanctions seem to have failed. And already some are suggesting that these sanctions should be stiffened.

In the long-run, there is the issue of whether a sufficient consensus — involving both developed and developing countries as partners in decision-making — can be forged to develop and apply an effective control regime; or whether increasing competition between both producers and consumers of nuclear power will be such as to limit the possibilities for multilateral action, shifting the focus back to bilateral actions. At this stage, nobody pretends to have all the answers. □

US adopts new cancer policy

NEW guidelines setting out a common framework for both the scientific assessment of potential carcinogens and the appropriate regulatory mechanisms were announced by the US Government last week. The guidelines, described as a "Government-wide cancer policy", were published by the regulatory council set up by President Carter last October to coordinate federal regulations in general. (See *Nature* 27 September 1979 p244).

On the scientific side, the council supports that view that animal tests are a valid method of determining whether a substance should be considered a potential carcinogen. It also says that a single animal test, if properly conducted, is sufficient to indicate "a potential risk to humans" for regulatory purposes — a view contested by the chemical industry in current debates over the proposals of the Occupational Safety and Health Administration to establish a "generic carcinogen policy".

Referring to claims that a single positive test is not enough, the council says that "although the agencies should attempt to obtain additional data, they should not take the risk involved inwaiting two to four years" to conduct further tests before taking action. At the same time, the council has gone some way to meeting industry's demands by caling on agencies to ensure that proposals for regulating carcinogens are accompanied by some form of risk assessment, including in particular determining how many people are exposed to the substance.

The council implies that economic considerations should be included, urging agencies to identify and consider the least costly and least disruptive course of action in planning cancer controls. It also says that agencies should consider "zero risk" bans in cases where the economic and social costs are considered minimal.

"This new policy will ensure that the various agencies will operate from the same scientific base in determining whether a compound is carcinogenic", Mr Doug Costle, chairman of the Regulatory Council and head of the Environmental Protection Agency, said in announcing the new guidelines.

David Dickson

School for scandal?

Soviet University admissions procedures are being circumvented by over-ambitious parents, *Pravda* alleged recently. The offenders, it claimed, are making use of their professional position or contacts to obtain their children a priority position on the placement lists.

Admission to Soviet Universities and other higher educational institutions is by competitive examination. However, even for those who have passed the examination, there may still not be enough places. Priority is therefore given to "front-rankers" from agriculture or industry, who are recommended and supported by their former place of work, to which it is assumed they will return.

This priority scheme is intended to provide Soviet production with the specialists it needs where and when it needs them. Modifications are made from time to time to meet specific demands. Thus the normal length of service needed for a "front-ranker's" place is two years. However, in April of this year, workers sponsored by the Ministry of Land Reclamation and Water Conservancy were exempted from any minimum length of service presumably due to pressing demands for graduates in that sector.

Although no less than four signatures and an official seal are needed on the "front-ranker's" sponsoring form, "crafty parents" says *Pravda,* are managing to equip their sons and daughters with false papers. Not surprisingly, those who graduate under such auspices are in no hurry to start working at the farms or enterprises which sponsored them. Not surprisingly, too, a number of the alleged "front rankers" have been abondoned in mid-course by their "sponsors" and have had to apply for state maintenance grants. Last July, the Central Committee of the Communist Party of the Soviet Union and the USSR Council of Ministers adopted a new decree on the "Further Development of Higher Education and Raising the Standard of Training of Specialist".

"Before you go in, stick this chicken under your arm and put some manure on your boots!"

This provides for a new procedure of job allocation. By fixing a student's future job some two or three years before he or she graduates, the "output" of young scientists and technologists will, under the new system, become part of the normal Five Year Plan. Moreover, and particularly in the Far North and Siberia, measures are envisaged to retain the graduates in the area on a permanent basis.

Parents about to furnish their children with the certificates of Arctic lumberjacks would be well advised to think twice.

Vera Rich

Superpower clash over test ban technology

Delegates to the Geneva talks on a comprehensive test ban, currently nearing completion after almost two decades of negotiation, have reached an impasse over USSR demands that only Soviet equipment be used for the seismic monitoring on Soviet soil.

Until three months ago the US had assumed that the Soviet Union would permit the use of American detectors on its soil. Data from the detectors will be used to verify that seismic disturbances are the result of natural causes and not the undergound testing of nuclear weapons banned under the terms of the treaty.

However in June members of a US Congressional delegation visiting Moscow were told by Soviet officials that they would only permit Russian equipment to be used for this purpose — a condition which, in the eyes of the US politicians, would make the treaty unacceptable.

"We feel that it is essential to use US equipment to verify Soviet compliance; and that this point is so central that we cannot allow the test ban talks to proceed unless this is resolved," an aide to Representative Jack Kemp (Rep, New York), said recently.

State Department officials in Washington have been playing down the significance of the USSR demands, claiming that they see them as essentially a negotiating tactic which will be dropped in return for some concession from the US side. They have already rejected a request from Mr Kemp to cancel a visit by Soviet scientists last month to study US seismic technology — a visit which Mr Kemp described as "scientific espionage".

Furthermore seismic experts in the US feel the USSR would have little to gain from insisting on the use of their own equipment, since the US already possesses suitable equipment that can be bought "off the shelf"; existing Russian equipment, it is claimed, lacks either the dynamic range or the precision of US seismic sensors.

Others involved in the negotiations, however, maintain that although relatively trivial, the issue is the sort which could seriously delay completion of the treaty, since no quick way out of the impasse can currently be seen. Any such delay could also effect the outcome of the second Non-proliferation Treaty Review Conference, which takes place next spring, and at which the non-nuclear powers will demand evidence from the nuclear powers of steps which have been taken to prevent escalation of the nuclear arms race.

Congressional aides said in Washington last week that they expect the issue of Soviet technology to be raised dring hearings on progress towards the test ban treaty due to be held by the House Armed Services Committee later in the autumn. ☐

news in brief

"Employers need freedom": Mr Mark Carlisle, UK Secretary of State for Education and Science has refused to establish an enquiry into the problems of short term contract researchers. In a letter to the Association of Researchers in Medical Sciences (ARMS) the minister's private secretary transmitted Carlisle's sympathy for those on short term contracts and his reluctance to see "good research wasted because it had to be ended prematurely". But, in accordance with current Conservative philosophy, Carlisle affirmed the importance of the employer in economic development. "On the other hand, the effective development of research is liable to be hampered unless employers have sufficient freedom to manoeuvre." An ARMS spokesperson said the government's response was "dismal."

Piperno hearing postponed: Extradition hearings in Paris for Franco Piperno, the Italian physicist accused of anti-government activities (27 September) have been postponed until 27 October. In the meantime, the French civil liberties organisation CINEL (Centre d'initiative pour des nouveaux éspaces de liberté) has raised questions about the prison conditions of Piperno and another detainee, Lanfranco Pace. In Italy 60 Milan lawyers have issued a statement opposing the extradition. The lawyer's statement accuses the Italian authorities of not wanting a true public inquiry but instead "to submit (Piperno and Pace) to a long preventative detention in special well known prisons."

India-USSR to collaborate on solar energy: An Indian team of scientists which visited USSR in July has signed an agreement to collaborate with the USSR on a programme of solar energy utilisation. The programme invisages the development and testing of selective surfaces and solar collectors, solar thermoelectric generators and an autonomous power station using a Stirling engine. The joint work will be carried out at Central Salt and Marine Chemicals Research Institute, Bhavnagar; National Physical Laboratory, New Delhi; Kryzhizhanovsky Power Engineering Institute, Moscow; and the Institute of Physical Studies, Tashkent. *From Zaka Imam, New Delhi.*

New Finnish nuclear incident: Following recent difficulties with the Soviet built Loviisa nuclear power station, a radioactive leak occured at the Olkiluoto-1 station, which is of Swedish origin. The incident on 29 August took place when the station was working at 65% capacity. A pipe in the reactor water purification circuit burst, and some 5 m^3 of radioactive water escaped on to the floor. All safety systems worked satisfactorily, and, according to the Teollissuden Voima (Industrial Power) Company which owns the station, the leak was immediately isolated and the station shut-down. After tests by the Radiation Protection Institute, the station was allowed to recommence operation on 3 September. The shut-down had no effect on Finland's plans for nuclear energy expansion. While Olkiluoto-1 was still out of action, the Council of States granted an operating licence of Olkiluoto-2 (subject to final checks). This second set is expected to commence generating at the beginning of 1980 and to reach full capacity by the middle of the year.

More Windscale troubles: Thirty people had to be evacuated from a low level effluent treatment plant on 12 September when radiation alarms sounded in the early morning hours. Plutonium was part of the radioactive airborn release but the details on levels or amounts is not known. A British Nuclear Fuels spokesperson said that tests have shown "no signs of harmful contamination". The cause of the alarm and the source of the leak are the subject of an internal inquiry. In the meantime the inquiries into the fire in the decanning cave last July in which 8 workers suffered radiation exposure (26 July) and the sump leak last March that discharged 30,000 curies under a temporary storage building (26 April) are "still proceeding."

IEA launches International Energy Conservation Month: International Energy Conservation Month for the 20 members of the International Energy Agency began on Monday. To increase consumer awareness of the need for energy conservation, the IEA member states are organising 30 international conferences and exhibitions to take place during October in different cities throughout the world, as well as individual national events including local meetings, exhibitions, demonstrations and competitions for school children. In addition, two countries, the US and Japan, are using the month to launch new legislation on energy conservation. President Carter, for example, is expected to announce the enforcement of the 55 mph speed limit and the issue of a gas mileage guide.

Plant physiologist expected to be named head of new US research foundation: Dr Nyle Brady, currently director of the International Rice Research Institute in the Phillipines, is expected to be nominated by President Carter as the director of the new Institute for Scientific and Technical Co-operation (ISTC), which will become the focus of US research efforts on issues directly related to the needs of developing countries. Two of Dr Brady's principal research interests have been the fundamental effects of lime in soil, and the physiology of the peanut plant (an interest which White House officials deny had any bearing on his appointment). Other research interests include the influence of fertiliser on the yield of rice, corn and coffee, and the influence of soil temperature on nutrient uptake.

Meanwhile the Senate appropriations subcommittee last week approved an allocation of $19.75 million to the ISTC for the fiscal year beginning 1 October 1979, in addition to funds transferred from programmes currently under the Agency for International Development. However the institute's budget figure still has to be approved by the full Senate appropriations commitee and by the Senate itself — at both of which stages it is expected to meet with opposition — before the institute can be assured that it will be allowed to start functioning.

US agrees to increase research cooperation with Japan: The United States and Japan have agreed to increase cooperation on scientific and technological research into non-energy fields, a move which follows an earlier agreement to cooperate on energy research. The broad framework for cooperation was agreed at a meeting in Tokyo last week between as US delegation headed by Dr Frank Press, director of the Office of Science and Technology Policy, and a Japanese delegation headed by Mr Moyazaki, deputy minister for foreign affairs.

Following summit talks held last May, a communique was issued stating that the two governments "will study seriously the prospects for cooperative efforts in areas of basic and applied research", adding that promotion of joint cooperation was important in building up a partnership between the two countries for the 1980s.

No details have yet been announced of specific areas for joint research activities. However possibilities include, outer space development, and environmental and health research.

Bombay magnetic observatory may move: The Colaba-Alibag Institute of Geomagnetism, with its 133-year-old record of continuous magnetic observation, may be moved if electrical noise from a nearby fertiliser complex disrupts its function. A campaign (*Nature* 15 February) to have the fertiliser complex at Thal-Vaishet resited has failed, in part because the state government of Mararashta opposed the move because of the loss of jobs resiting would have entailed.

A number of experiments on the effects of electromagnetic noise have so far proved inconclusive, however, and there is still the possibility that the observations will be unaffected by the plant's machinery.

Burying Britain's radioactive waste

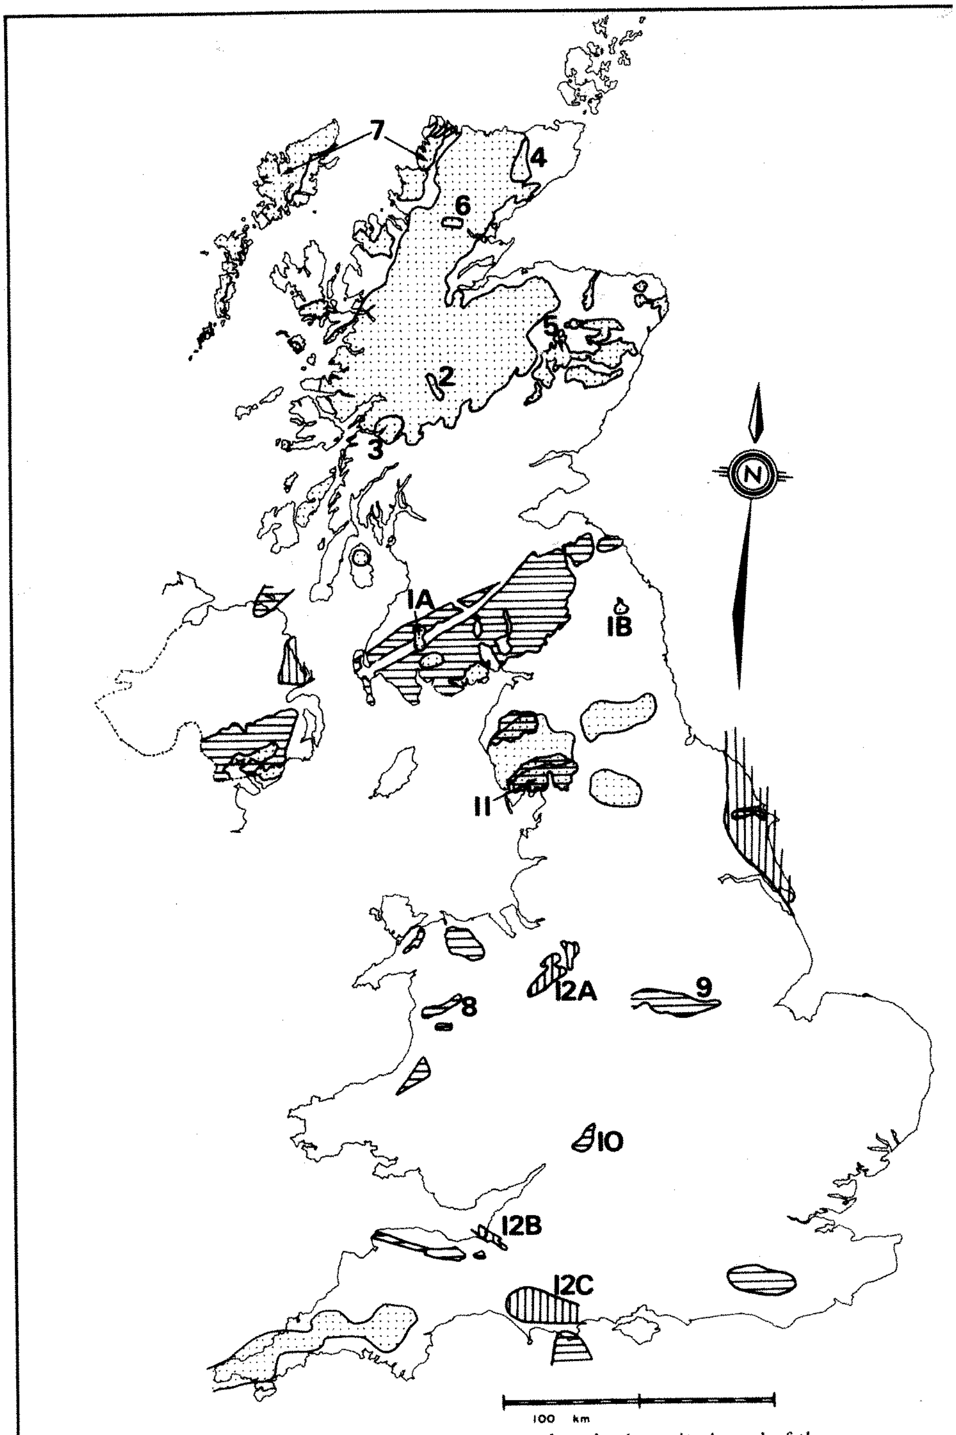
— the geological areas under investigation

By J D Mather, D A Greenwood and P B Greenwood of the Institute of Geological Sciences

OVER the next decade a major research effort is planned in the United Kingdom into the feasibility of the disposal of solidified, highly-radioactive, heat-emitting wastes to geological formations. Such research was called for in the Sixth Report of the Royal Commission on Environmental Pollution published in 1976[1] and accepted as one of three possible disposal options in the Government's White Paper[2] of 1977. These are disposal:

- on the bed of the deep ocean,
- into stable geological formations on land, and
- disposal under the bed of the ocean.

Parallel studies into all three options in relation to high-level wastes are being undertaken but the land option has progressed rather further than the oceanic programmes. The White Paper recognised that the Natural Environment Research Council's Institutes of Geological and Oceanographic Sciences will play an important part in this research and relevant programmes are now under way at both Institutes. Criteria for use in the selection of areas under land which contain geological formations potentially suitable for such disposal in the United Kingdom were published in 1976 by a Working Party established by the Council's Institute of Geological Sciences[3]. A recent comparison of the criteria with those published elsewhere has indicated a high degree of international agreement, so that no significant revisions are necessary[4].



Map showing the distribution of rocks thought to meet the selection criteria and of those areas which have been selected for feasibility studies. Crystalline igneous and metamorphic rocks are stippled, argillaceous rocks are shown with horizontal lines and evaporites with vertical lines. The crystalline rocks include the postulated subsurface outcrops of the granites of northern and south-western England. No rock types meeting the criteria occur in the Shetland Islands.

The principal objective of disposal of these solidified wastes into geological formations is to ensure that they are placed in a situation where the radionuclides cannot be returned to the biosphere in amounts constituting a biological hazard. In reality that means placing them in a repository constructed at depth in a geological formation or rock mass able to withstand the effects of decay heat and radiolysis and sufficiently free form circulating groundwater to ensure their containment[5,6]. The programme is planned in a series of stages of which the present proposals relate to the exploration phase, during which no radioactive wastes will be used. Some sections of the UK national research programmes are being mounted jointly with the Commission of the European Communities.

The application of the geological criteria results in the recognition of 127 different areas containing potentially suitable host rocks. These range in area from less than 5 km^2 to around 6,000 km^2, the mean being around 260 km^2. Of these areas, 104 contain crystalline igneous or metamorphic rocks, 17 argillaceous rocks (fine grained sediments consisting principally of clay minerals) and six evaporites, including hybrid evaporite/clastic sequences. The distribution of the areas involved is shown in the map above and covers nearly 39,000 km^2, approximately 16% of the land area of the UK.

In order to select representative areas for feasibility studies a further desk study was undertaken using as primary factors the geological environment and the evolutionary history of the rocks concerned, so far as they are known. The groups thus obtained were then further

Areas for further study

Crystalline rocks

1. Caledonian granites intruded into (1A) Lower Palaeozoic sediments or (1B) volcanic rocks. The Loch Doon Granite (Intrusion 1A) is a zoned body with an outer unit of biotite tonalite merging progressively into a central unit of biotite granite. It is intruded into Ordovician sediments of various types, predominantly greywackes, but with significant developments of black shales and cherts and has a sharp contact with an extensive thermal aureole. The Cheviot Granite (Intrusion 1B) varies in composition from a pyroxene granite to a pyroxene-free granophyre, is intruded into andesite lavas and has a faulted brecciated contact.

2. Caledonian granite forcefully intruded into Pre-Cambrian metamorphic rocks. The Ossian Granite is a coarse hornblende-biotite tonalite varying to granodiorite towards the outer part. A number of SW-NE trending fractures cross the granite which is intruded into metamorphosed sediments belonging mainly to the Pre-Cambrian Moine Supergroup. No thermal aureole is developed but the intrusion margin is generally intimately welded to the country rock by the development of contact migmatites.

3. Caledonian granite permissively intruded into Pre-Cambrian metamorphic rocks. The Etive Complex is a ring complex composed of 4 successive granite intrusions emplaced as a result of progressive cauldron subsidences. The innermost unit known as the Starav Granite is a quartz adamellite which has a simple, near-vertical contact and is free of dykes.

4. Granitic complex in the core of a regional migmatite zone. The Strath Halladale Granite occupies the core of an injection complex within metasediments of the Moine Supergroup. The injected material is dominantly biotite grantite of variable grain size which occurs as veins or concordant sheets within the psammitic host.

5. Caledonian basic intrusive. The Morven/Cabrach Intrusion is mainly composed of norites with associated gabbros and diorites. It is steepsided with steeper dips on the west than on the east, implying an increase in width at depth. Much of the intrusion is extensively altered with pyroxene replaced by amphibole.

6. Non-migmatised Pre-cambrian Moine Metasediments. The rocks of the Moine Supergroup consist of thick metamorphosed arenaceous and argillaceous sediments with some intermediate types. The area around Inveroykell is being considered within a region of massive to flaggy quartzo-feldspathic psammi of intermediate metamorphic grade and relative lack of structural complexity.

7. Pre-Cambrian Lewisian basement rocks. The Lewisian includes relics of several orogenic cycles covering a time span of at least 2,800 my to the latest reworking at 1,600 my. The major sub-division is into two time-based complexes, the older Scourian and the younger Laxfordian. The Laxfordian rocks are dominantly grey quartzo-feldspathic and biotite hornblende gneisses with intrusive sheets and veins of granite and pegmatite. The gneisses have undergone thorough re-working resulting in rock units that are relatively homogeneous compared with much of the rest of the Lewisian basement and appear the most suitable as a disposal medium. Such rocks occur in North West Scotland, between Loch Laxford and Cape Wrath and in the Outer Isles, but so far no specific research area has been identified.

Argillaceous and evaporite formations

8. A series of gently folded Ordovician and Silurian rocks in North Wales dominated by argillaceous types totalling some 4,000 m in thickness. The rocks are well exposed at the surface and dip consistently to the south-east at an angle of about 45°.

9. A sequence of turbiditic mudstones with interbedded siltstones and limestones of Lower Carboniferous age. The rocks occur within a fault bonded trough known as the Widmerpool Gulf and a minimum thickness of 1,000 m of argillaceous rocks is available. These rocks constitute a good example of the effective compromise desirable in argillaceous rocks — a thick formation that has been dewatered and developed a mature clay mineralogy by deep burial, without the attendant development of structural complexity.

10. A mudstone dominated sequence of Triassic rocks attaining thicknesses just in excess of 500 m in the central part of the Worcester Basin. These occur within the evaporite-free part of the major depositional basin with a cover of up to 500 m of mainly argillaceous rocks of Jurassic age.

11. A series of Silurian mudstones and greywackes in Southern Cumbria with an overall thickness of around 5,000 m. These rocks are folded on both a large and small scale and are cleaved to a lesser or greater extent depending on lithological variations.

12. Hybrid evaporite/mudstone sequences within Permo-Triassic sediments developed in the Cheshire (12A), Somerset (12B) and Wessex Basins (12C). These are all major depositional basins where the rocks of interest are in excess of 600 m in thickness and are generally overlain by other argillaceous formations. In all these areas examination of the cyclicity of the hybrid sequence from the point of view of waste containment is a particularly important aspect.

divided on the basis of compositional differences, degree of consolidation (for argillaceous rocks), structural complexity and other aspects to produce a tentative order of preference based entirely on geological factors. It must be emphasised that this order of preference is necessarily based on subjective judgements; if the data were available for an objective analysis there would be no need for the present research programme.

As the programme advances and more data become available it can be expected that some areas will be rejected and others introduced. It should also be noted that the areas selected relate to high-level wastes and that other formations in additional areas may be relevant to the disposal of intermediate and low-level wastes.

Crystalline rocks

Using the order of preference, 23 crystalline rock areas were selected for more detailed investigations, including reconnaissance field visits where possible. These 23 areas included a wide range of geological environments test the validity of the aproach on which the grouping had been based. A combination of those studies and selection based on the non-geological factors of land ownership and access to drilling sites resulted in selection of eight areas within seven different geological environments for detailed research into the feasibility of geological disposal of high level wastes into crystalline metamorphic and igneous rocks. Detailed analysis is required to relate the primary factor, groundwater flow, to rock mass and rock material parameters, such as mineralogy and petrology, joint frequency, attitude and openness, and regional stresses. A data base can then be considered so that the most appropriate crystalline environments for consideration as repositories can be defined.

The geological environments chosen for the future feasibility studies, and the individual areas concerned, are shown in the map and a brief description is given alongside.

Before work proceeds at any of the prospective research sites applications have to be submitted under the planning regulations for permission to drill investigatory boreholes. So far such applications have been submitted for sites within the Loch Doon Granite (Area 1A), the Cheviot Granite (Area 1B) and the Strath Halladale Granite (Area 4). Only the latter has been granted and the others are at present the subject of appeals. The research site within the Strath Halladale Granite occupies some 100 km^2 within the Caithness District and is peat and drift covered with only limited exposure of bedrock.

A preliminary drilling programme has been undertaken to confirm the limited geological information previously available and three boreholes have been drilled to 300 m, together with 24 boreholes to some 40 m. The data obtained from the boreholes complemented by field mapping, surface and borehole geophysics and detailed hydrogeological measurements are being used in a preliminary review of the containment characteristics of this particular geological environment. Similar studies are planned for the other research sites in the crystalline, argillaceous and evaporitic host rocks.

Argillaceous rocks and evaporites

The approach used in the studies of the feasibility of geological disposal to argillaceous rocks and evaporites is broadly comparable to that used for the crystall line rocks and total of seven preferred areas have been selected. The geological factor particularly relevant to the selection of these areas is the predictability of their mass characterstics. Impersistent developments of minor lithological variations may not pose problems but the presence of, for instance, a thin calcareous sandstone within an otherwise uniform greywacke/siltstone sequence, could be of major significance from the viewpoint of waste containment.

A useful property of plastic clays is their potential capacity for self-sealing. With progressive compaction and burial this property will be lost but will be countered by an increase in thermal stability as a result of the expulsion on non-structurally held water. As these changes are mutually exclusive an intermediate compromise has generally been sought involving for instance selection of areas containing uncleaved mudstones.

Although salt domes occur beneath the UK Continental Shelf they appear to be absent beneath the land mass and the evaporite formations available are all bedded deposits. These generally occur within thicker argillaceous formations and are gybrid sequences containing interbedded evaporites and mudstones and/or siltstones.

The areas containing argillaceous and evaporite formations which have been selected provisionally for more detailed study are also shown in the figure and briefly described in the box.

It is hoped to mount studies to examine the feasibility of geological disposal to argillaceous rocks at sites in each of areas 8-11 and at one site within areas 12A-12C for preliminary studies on the hybrid evaporite/mudstone sequences. Work has not advanced as far as with the crystalline rock studies and at the present time no research sites have been identified and no applications for permission to drill boreholes have been submitted.

Conclusions

The feasibility of the disposal of high-level radioactive wastes within the geological framework of the United Kingdom still remains to be demonstrated. The immediate need is for comprehensive site-specific field data from a range of potentially appropriate geological environments both to test the criteria on which these environments were chosen and to provide a data base from which potential disposal sites may be identified. The feasibility studies suggested represent a major step towards these objectives and need to be initiated as a matter of urgency.

Sun-soaked but blind to solar power

ON the counters of the Caixa General de Depositos, the largest government bank in Portugal, bright orange folders decorated with a smiling Sun attract everyone's attention. They announce credit facilities for equipping private homes with solar water heaters. Up to £500 loans can be obtained at 10% interest over 10 years, an extraordinary bargain in a country where inflation reaches 50% a year and interest rates on short term deposits are 20%. "The response, however, has been minuscule" says a bank official. "There is no echo of interest in the public; people just don't know what it is."

The first installation financed by the Caixa was hastily inaugurated on June 23, a Saturday christened Sun Day, in a village 20 miles south of Lisbon. Here a successful architect has equipped his new country home with three solar panels in the garden. This 300 litre system cost £800. The installer, Mr Falconer, is a British subject and one of the two pioneers of solar energy installations in Portugal. He told *Nature* "the bank wanted publicity, but the house was still not finished at the time of the inauguration; so we connected a plastic hose to the plates to prove to the press that they heated the water." Falconer's firm has been importing MIROMIT plates — selective coating plates developed by the Tabor group — from Israel since 1961.

The other solar energy pioneer is Mr Neves da Silva, who obtained a Portuguese patent for a simple painted flat solar collector in the early 1960s. He is director of PRETEC, a mechanical construction firm, and he first attempted to build his collectors from national materials. "We tried to use cork, Portugal's main export product, as an insulator, but the price was too high; so we have to use glass wool like everyone else."

Both men are enthusiastic practical engineers. They have believed in solar energy for the past twenty years in spite of general indifference and incredulity. "In the sixties I had to deal with an engineer who stayed up all night hoping to catch me heating up the water in the reserve tank with an electric resistor. That was the only way he could imagine I could get hot water during the day from my system" recalls Mr Falconer.

"In the early days solar energy was no more than a toy for the very rich. Today it may still be mainly 'to show to the English', as the Portuguese saying goes." Indeed, a stone's throw from the casino in the resort town of Estoril on the fashionable Costa do Sol stands a huge mansion which is, according to its owner, the only solar equipped house and swimming pool in Portugal. Among the bougainvillea trees and parterres of geraniums are interspersed rows of solar collectors; the mansion itself displays several striking black overhangs on the south side. "My pool is heated up by 24 panels; my family has used it 90 days per year since 1961" says Virgilio Gomes Borges, one of the brothers of the Borges Brothers Bank. "I use 32 panels in the sanitary water circuit; additional heat storage is provided by the electrical company's reduced night rates."

Using the Sun's light remains an elitist activity haphazardly conducted in the midst of abundant talk about energy crisis on the one hand and Portugal's exceptionally favourable climatic situation on the other. Tourism officials claim 244 sunny days per year. A more objective but no less encouraging way of rating Portugal for its potential is through its atmospheric transmission ratio — of the energy received on a horizontal surface on the Earth to the energy received on an equal surface at the top of the atmosphere, averaged over a year. According to Dr Collares Pereira, the only Portuguese physicist with a PhD in solar energy work, that ratio varies between 0.3 for high latitude rainy climates and 0.7 for clear desert locations like Albuquerque in New Mexico. Lisbon's ratio is 0.65 (and the south of Portugal is considerably sunnier) while New York and New Jersey, at the same latitude, hardly reach 0.5.

The local capacity for building solar plates has improved over the years. Mr Neves da Silva remarks that back in 1962 he operated as "an artisan", but today PRETEC would be capable of producing 100 collectors per year. What is missing, however, are serious orders and some planning and stimulation on the part of the government. At the opening session of a Franco-Portuguese seminar on solar energy last March, Mr Sidonio Pais, General Director for Energy of the Ministry of Industry, declared that it was impossible for him to be specific about solar energy developments at the moment because "our government does not have yet an energy policy".

At the same seminar, the Secretary of State for Higher Education praised the ecological advantages of solar energy but spelled out no plans for the future.

In the private sector several religious schools have put up collectors to heat up sanitary water. "It is quite well adapted to the kind of financing that this type of institution can do" says Neves da Silva who built the systems, "religious groups can easily raise money once-off for such a project, and solar heating does not give rise to monthly costs afterwards."

For the future the Ministry of Health has in its files a construction program for 27 health centres throughout the country, each equipped with 75 solar panels for sanitary water heating. It should come up for bidding soon.

'Those who attack nuclear energy show a cynical denial of human ingenuity'

THREE Mile Island confirmed what many of us in the nuclear enterprise had suspected — that the "China Syndrome", rather then proliferation or even waste disposal, would ultimately decide the public's acceptance of nuclear energy. Nor is this unreasonable. Proliferation is an issue far from most people's perception; more than that, it faults nuclear power by association, not by intrinsic connection. As for waste disposal, despite the violent arguments, the nuclear community could always point to plausible technical solutions for wastes (one must remember that 800 years after wastes are created, their toxicity has fallen below that of the original uranium from which the wastes were created). But for the 15 billion curies contained in a 1000 megawatt reactor, we could never say that the chance of a serious accidental release was zero. Three Mile Island carried this message directly to the public; the public must decide whether it can accept this risk. Chancellor Schmidt's recent call for an international review of safety as a sequel to the International Nuclear Fuel Cycle Evaluation study of proliferation resistance is therefore most appropriate.

The fact that deaths caused by nuclear energy, are on average, considerably fewer than those estimated for most energy sources (including many solar sources if they are backed up by non-solar systems), seems to me rather beside the point. Risk as perceived by the public is not simply the product of probability and consequences — the first moment of the probability distribution of consequences. The very high moments of the distribution — very low probability high consequence events that contaminate large stretches of land — are probably more important. Thus a most important technical fix for nuclear energy would be a means of minimising the amount of land that conceivably could be contaminated in the worst possible accident. Siting reactors underground could achieve this, though at considerable expense. The recently published report on ungerground siting to the California Energy Commission concludes that comparable improvements can be achieved at much lower cost with more elaborate containment systems.

Three Mile Island suggests that even an accident that imposed an average additional radiation burden 1% of the natural background on those within 20 miles is unacceptable. For nuclear energy to survive, we must reduce the probability of *any* serious malfunction much below the 1 in 20,000 per reactor-year estimated in the Rasmussen report, as well as reducing any possible consequences.

Can we fix nuclear energy? I believe we can, but it will require important institutional changes as well as better technology. I am therefore most enthusiastic about the plan announced earlier this year by the Tennessee Valley Authority, the largest electrical generating entity in the United States, in response to Three Mile Island. The main elements of the TVA plan are:

- the establishment of a separate operating entity with the Office of Power that is responsible only for nuclear generation;
- the establishment of an independent Nuclear Safety Review Board that reports directly to the Board of Directors of TVA;

Alvin Weinberg (right) explains why, despite the Three Mile Island accident, he is still a believer in nuclear energy

- the professionalisation of the cadre operating nuclear reactors — operators will receive training equivalent to a bachelor's degree, and salaries high enough to attract and keep the best, even though this places them at an advantage as compared to operators of fossil fuel or hydroelectric plants;
- more extensive plans for evacuation, and for keeping the public informed on the status of its nuclear plants.

In addition to these institutional changes, TVA is, on its own, proposing a number of technical improvements for its reactors that go beyond what the Nuclear Regulatory Commission requires. TVA, being the largest American utility, is well equipped to analyse and then implement safety mesures that a smaller utility might not be in position either to recognise or to pay for. It is to TVA's credit that one of its safety engineers, C. Michelson, had visualised essentially the Three Mile Island sequence a year before it actually happened, and had called the attention of Babcock and Wilcox, (the nuclear steam suppliers) and the Nuclear Regulatory Commission to the deficiency.

Although not mentioned in their plan, I would hope that TVA will confine future reactors to its existing seven sites rather than allowing nuclear sites to proliferate. The sites would be expected eventually to develop into powerful nuclear centres. They would be invested with a commitment of permanence: spent fuel elements, low level wastes, and decommissioned reactors could be stored for a long time on them. After 100 years the high level wastes would be producing little heat and the low level wastes and reactors, though not innocuous, would be much easier to handle.

The TVA plan, together with confinement of the nuclear enterprise essentially to existing sites, seems to me to constitute an acceptable nuclear energy system. TVA, being large, self-contained, and able to set its own rates, is better able to implement such a policy than are most of the private utilities. But I believe the private utilities ought to move strongly in this direction — by establishing *nuclear* generating consortia, perhaps like the Yankee Atomic Electric Company, in each of the nine regional Reliability Councils; or possibly by assigning generation of all nuclear energy in a region to a single utility that has the strength to take on this responsibility. Such a nuclear generating company, from the president down to the operators, would think, act, and know the nuclear business, with all its responsibilities and hazards.

Will an aggressive acceptance by the US, or even the whole world, of some version of the TVA plan plus confined siting and technical fixes, be enough to tide nuclear energy over the present disaffection? I certainly hope so. The TVA plan, with its standby mobilisation of experts to respond to any contingency, ought to give fullest opportunity for the exercise of human ingenuity. The serious nuclear accidents, though they were precipitated by human error, were contained by human ingenuity. At Three Mile Island, shutting off the high pressure injection pumps was perhaps the key operator error; but only 12 curies of ^{113}I were released — some 2000 times less than was released at Windscale in 1958. A key manoeuvre in preventing more iodine from escaping was the replacement of the iodine filters a few days after the incident began. This was carried out faultlessly by experts from various nuclear installations.

I consider myself to be a not uncritical advocate of nuclear energy: an advocate because I believe we need nuclear energy and the alternatives to it are faulted; not uncritical because I have been close to the technology for enough years to recognise its deficiencies. Despite Three Mile Island, I remain an advocate. Those who wish to extirpate nuclear energy base their position on an unquestioning acceptance of human fallibility and a cynical denial of human ingenuity. The two major accidents in the United States, Browns Ferry and Three Mile Island, suggest to me that this is an unjustifiably pessimistic assessment of the human condition. Rather, as the TVA Plan reveals, there is much room for creating institutions that will encourage ingenuity, and on which we can base an acceptable nuclear energy. □

'Beast and Man'

Sir, — I have only just seen Professor Stuart Sutherland's very interesting review of my book *Beast and Man* (28 June page 83.) May I say something in reply to the difficulties he raises?

He says that the main aim of my book "seems to be to establish a secure basis *for ethics*" and that, like "most previous attempts to establish a secure basis *for an ethical system*", it fails. (The italics are mine). Two projects might be meant, of which the first is certainly not mine —

- A "secure basis for an ethical system" would be a justification of one particular set of moral views against others. This would itself be a piece of ethical reasoning.
- A "basis for ethics" by contrast seems to mean something much more general — a justification or explanation, from outside, of the whole range of thought which can be called ethical or moral. Confused people often run these two enterprises together, supposing that the second will do the work of the first. I think this is what Professor Sutherland objects to, and I share his objection. There can be no moral justification of morality as a whole any more than there can be a mathematical justification of mathematics as a whole; neither from outside nor from inside these areas of thought would such an enterprise make sense, nor is it needed. In the case of morality, the notion that it is needed, and is lacking, stems largely from Nietzsche's ambiguous talk of 'immoralism'. Nietzsche often spoke of this as a comprehensive attack on the very possibility of morality. But in fact his campaign was an intelligently limited one, directed against certain particular human weaknesses and particularly against contemporary bourgeois notions. It was conducted in entirely moral terms, powered by fierce and unmistakeable moral indignation, and successful so far as his readers approved of it. It was a piece of ethics. The wider program of attacking or justifying morality as such remains obscure.

It was therefore no purpose of my book to provide defence agains this hypothetical general attack. I am interested, as most serious moral philosophers have been, in explanation rather than in instant justification, in understanding rather than in proof. For ethics as for any other area of thought, we need to *understand* our basic concepts, to resolve conflicts among them, and to relate them systematically to those used in relevant neighbouring fields. That is the sense in which people speak of the 'foundations' of mathematics. Nobody supposes these to be a set of non-mathematical arguments, guaranteeing mathematical truths from outside. In the case of ethics, however, people do for some reason tend to expect this, and even when they give their attention to the concepts, have a remarkable tendency to insist that they shall be simple. Hume's question, 'whether the foundation of morals lies in reason or in feeling?' has been only one of a whole series of grossly over-simple dilemmas, which it is the point of my book to defuse. I draw attention to the complexity of the relevant facts, to the unreality of various simple rulings, and particularly of those, fashionable in the first half of this century, which isolated moral thinking from the natural facts. During this epoch, a variety of reasons were given for tabooing many useful, indeed essential, concepts such as 'natural' which refer to facts, but are necessary to explain our value judgments. I do not think I can now trespass on your space with a full answer to Professor Sutherland's worries about my treatment of these. But perhaps it will help if I emphasize that I do regard them as explanatory, and not as an underhand short cut to justifying local prejudice.

Yours faithfully,

Mary Midgley

University of Newcastle upon Tyne, UK

East Europe: valuable information

Sir, The need by science of 'extensive, systematic and friendly international ties' noted by your corresondent, Lee Lorch, (13 September, p 98) is one which I am confident is recognized by *Nature* and by the overwhelming majority of its readers. Having worked at various times in research laboratories in half a dozen countries, including the USSR, I have personally had the good fortune to benefit directly from existing ties and have, I hope, made a modest contribution to furthering them.

Lee Lorch accuses *Nature* of allowing itself to be used by propagandists "anxious to whip up an hysterical ill-will against East European science", an accusation so far-fetched that it would not merit refutation if it were not coupled with a scornful and vicious personal attack on your regular contributor, Vera Rich.

Her articles are a valuable source of information about science and technology in Comecon countries. Of course it is incomplete, of course it is biased; Ms Rich writes rather more often on environmental matters than on high energy physics, and as far as I know has never written about Polish research in general relativity. But omission and bias are not the same thing as prejudice, still less contempt and propaganda.

To be sure there have been occasions, sad to say not infrequent, when she has reported on the action of the authorities against individual scientists, their dismissal from employment, arrest, or worse. The cases which she has reported have been in the USSR and in East Europe — but that is the region of her specialist interest and knowledge and others in your journal have balanced the record of injustice with reports from elsewhere.

The achievements of Soviet science are beyond question; the distinction of her scientists and engineers and their contributions to the advancement of knowledge command the admiration and respect of the world community of science. The mutual benefits that flow from international cooperation, the free exchange of ideas and the unrestricted travel of scientists themselves are widely recognized. Your journal indeed has a responsibility, the greater because of its eminence, to report on developments in science in East Europe as elsewhere. But it has a responsibility too to report with the candour and good faith of a true friend of international cooperation the less favourable aspect of the policies of those countries insofar as they affect science and scientists. To pretend otherwise is no way to encourage the ties of friendship: it is to acquiesce in injustice.

Yours faithfully,

John M Charap

Queen Mary College, University of London

'MHC' nomenclature

Sir, — Rolf Zinkernagel is too modest (14 June, page 618). The revolution which he and David Katz started has changed our thinking about the 'MHC' (major histocompatibility complex) to an extent which makes nonsense of the conventional nomenclature used in the otherwise excellent book which he reviews. His thesis is now generally accepted that MHC-coded molecules (other than complement components) evolved as signals for T cell subsets, which enable the immune system to make an appropriate choice between these subsets when combatting varied forms of infection. If one takes this point of view, present nomenclature is quite misleading. The very term, 'major histocompatibility complex' place the emphasis on transplantation, not infection. It perpetuates the historical accident which led to its discovery, but misleads as to its normal function.

Terms such as cytotoxicity-defined or lymphocyte-defined are open to the same criticism. The term 'I region' with the associated terms Ia-molecules, I-A, etc. implies falsely that H-2K and D molecules are not immunoregulatory. In fact, they are so, and in a way which appears exactly to parallel the immunoregulatory functions of Ia-molecules, except that they control cytotoxic T cells rather than helper T cells. Furthermore, gene substitutions at K and D regulate immune responsiveness of cytotoxic T cells just as substitutions in the I region regulate the responsiveness of helper cells. The whole complex, again with the exception of the complement components, seems to be equally immunoregulatory. Indeed, one really ludicrous usage is creeping in: to refer to the I-region genes as *the* IR genes. No doubt, many if not most gene substitutions perturb the immune system, just as most known substitutions perturb the nervous system: it's just that behavioural effects are more obvious.

We hesitate to suggest alterations, chiefly because it annoys others so much when one does so. T cell-activating complex? Cytotoxic cell activating molecules versus helper cell activating molecules? There are plenty of problems still: the aberrant presence of Ia-molecules in glandular epithelia and T cell products, the odd behaviour of I-J molecules, questions about restriction elements on B cells, and so on. What is certain is that so long as the present nomenclature is used we shall have to go on explaining to newcomers that the only way to understand the MHC - and hence what the majority of cellular immunologists these days are up to -is to forget about what the terms seem to mean.

Radio and the 'experts'

Sir, "A pity" — you say (23 August, page 619) — that more qualified people fail to participate in phone-in and open-line radio programmes.

The reason is simple: most of us are at work, so don't hear the programme anyway; those not at work presumably would not wish to advertise the fact!

Yours faithfully

I.P.C. Gaut

Vanadate — a new tool for biologists

from T. J. B. Simons

RESEARCH on the biological actions of vanadate has increased enormously during the past three years. Vanadium compounds can be highly toxic to man and animals and yet removal of the minute quantities normally present in the diet leads to deficiency disorders in experimental animals[1]. The biological basis for the apparent requirement for vanadium is still unknown but currently its effects on certain enzymes — notably the ATPases — are being studied intensively.

The stimulus to the present interest in vanadium came when vanadate was identified[2,3] as the impurity in ATP derived from equine muscle, which inhibited dynein ATPase[4] and the membrane (Na + K)-ATPase[5,7]. The impurity was present at only 1/3,000 the molar concentration of ATP.

Since then studies on both the physiological and the biochemical effects of vanadate have revealed a wide range of activity. Particularly interesting is its apparent selective inhibition on some ATPases, which has led to its use as a selective probe. It also inhibits several other enzymes (acid phosphatase[8], alkaline phosphatase[9], phosphofructokinase[10] and adenylate kinase[11]; on the other hand it stimulates adenyl cyclase[12]. It can replace phosphate as a substrate for glyceraldehyde 3-phosphate-dehydrogenase. This leads to the formation of an unstable analogue of 1,3-diphosphoglycerate, similar to that produced by arsenate[11]. Its physiological effects include diuresis, natriuresis[13], increasing the force of contraction of the heart[14] and vasoconstriction[15].

Two forms of vanadium in particular have been studied and have been found to have different effects. The first, vanadate, exists mainly as $H_2VO_4^-$ anions in dilute solutions at neutral *p*H, but it polymerises at concentrations above 10^{-4} M (ref. 16). Monomeric vanadate is structurally analogous to phosphate and this could account for its inhibitory effects on enzymes concerned in phosphate transfer or release reactions. Like phosphate, vanadate enters human red blood cells by the anion transport mechanism[17]. Inside cells however, vanadate often seems to be reduced to vanadyl ions (VO^{2+}) which bind to proteins[17-19]. Vanadyl ions have different effects from vanadate: they are powerful inhibitors of alkaline phosphatase, but seem not to affect the (Na + K)-ATPase[18,20,21]. One complicating factor in experiments is that vanadyl solutions are readily oxidised to vanadate by the atmosphere.

Inhibition of (Na + K)-ATPase

Cantley and Josephson have done much to characterise the inhibition of (Na + K)-ATPase by vanadate (ref. 22 and see refs therein). (Na + K)-ATPase is embedded in cell membranes and couples ion movements — Na efflux and K influx — to the hydrolysis of ATP. This is brought about through a phosphoenzyme intermediate, whose formation and breakdown are promoted by Na and K ions, respectively. The enzyme is dimeric, and shows both high and low affinities for ATP-binding and ATP hydrolysis[23]. The two halves are thought to be coupled in an anti-parallel fashion, with phosphorylation occurring on one subunit at about the same time as dephosphorylation occurs on the other[24]. Vanadate is a reversible inhibitor. It binds most strongly in the presence of high concentrations of Mg and K ions, when 40 nM vanadate gives 50% inhibition[2]. Detailed binding and competition studies show that it binds to two sites — a high and a low affinity site, and that vanadate at its high-affinity site competes with ATP at its low-affinity site[22]. Phosphate is a poor product inhibitor, and competes for the high-affinity vanadate site. This raises the possibility that the phosphate release site may be the same as the low-affinity ATP-binding site. It could imply that the ATP-binding sites go through a cycle of high and low affinities towards ATP, corresponding to phosphorylation and dephosphorylation, respectively. Supporting evidence is tenuous as yet: micromolar concentrations of vanadate only inhibit ion transport from the inner surface of the membrane[17,26], where ATP acts.

Another interesting point concerns the promotion of vanadate binding by external K ions. This requires much higher concentrations of K than are needed to stimulate the (Na + K)-ATPase, suggesting that in this case K acts at sites different from those which normally activate the enzyme[26-28]. When K is absent, ATP is still hydrolysed and Na efflux continues, but at slower rates. The enzyme now shows only high affinity sites for ATP[23], and vanadate inhibits the ATPase with relatively low affinity[22]. Internal vanadate has no effect on the Na efflux from squid axons in K-free sea water[26], in agreement with this observation.

Inhibition of dynein and other ATPases

Dynein is an energy-transducing protein responsible for the mobility of cilia and flagella. It can be extracted from them and shows a Mg-ATPase activity that is 50% inhibited by 0.1 to 1 μM vanadate[29,30]. Early experiments showed that vanadate does not inhibit myosin or actomyosin ATPases, except at much higher concentrations[29,31,32] and so can be used as a selective inhibitor to investigate cell motility. A difficulty with this kind of investigation is that the cell membrane is relatively impermeable to vanadate. For example, the flagella of sea urchin sperm are unaffected by up to 10 μM vanadate, but their beating is stopped by as little as 4 μM after the plasma membrane is treated with detergent[30]. Perhaps the most interesting observation has been made by Cande and Wolniak[32], who found that 10 to 100 μM vanadate inhibits chromosome movement and spindle elongation at anaphase in lysed mamalian tissue culture cells, which suggests a role for dynein in the spindle mechanism. More recently, Goodno has found that vanadate really is a powerful inhibitor of myosin, forming a ternary complex with ADP, but the onset of inhibition is so slow that it had previously been overlooked[33].

The sarcoplasmic reticulum (SR), and many cell membranes, have a Ca-ATPase, which couples Ca ion transport (out of cells or into the SR) to ATP hydrolysis. The SR enzyme has many structural similarities to (Na + K)-ATPase[34], so it is rather surprising that low concentrations of vanadate have no effect on it[31], although they do inhibit the red cell Ca-ATPase[35]. This point needs further investigation. The active transport of Ca out of squid axons seems to be partly dependent on external

---

T.J.B Simons is in the Department of Physiology, King's College, London.

0028-0836/79/400337-02$01.00

Na, and partly on internal ATP. Vanadate selectively inhibits ATP-dependent Ca extrusion[36], which suggests that it is brought about by a Ca-ATPase similar to that in the red cell membrane. Selective inhibition by vanadate might therefore be used to investigate the mechanism of Ca extrusion from heart, smooth muscle and other cells.

Physiological effects

There is an extensive literature on the toxic effects of vanadium salts, and some current observations, of effects on the heart or circulation for example, are not really new[37]. Recent work has shown that it exerts a positive inotropic effect (increases the force of contraction) in ventricular muscle, but a negative inotropic effect on cat and guinea-pig atria[39, 40]. Since the (Na + K)-ATPase in membrane preparations from both ventricles and atria is inhibited by vanadate, it must act on cell components other than the (Na + K)-ATPase. Action potential duration is lengthened by vanadate in guinea-pig papillary muscle (ventricle), yet shortened in atria[39]. This correlates well with the inotropic effect. Catecholamines have a positive inotropic action on the heart, lengthening the action potential, and augmenting inward Ca current. This is associated with a stimulation of adenyl cyclase and a rise in intracellular cyclic AMP[41]. Vanadate is known to stimulate adenyl cyclase[12, 40], so this could account for its positive inotropic actions, but not the negative effect in the atria. Obviously, much work remains to be done to understand the actions of vanadate on the heart.

Recently, deSousa and Grosso reported that vanadate blocks the cyclic AMP-induced stimulation of Na and water transport in amphibian epithelia[42]. The first finding, that Na transport is inhibited, can easily be explained by inhibition of (Na + K)-ATPase. The block of vasopressin- or isoprenaline-stimulated passive water permeability is much more interesting. Vasopressin increases the water permeability of many epithelia. This is associated with a rise in intracellular cyclic AMP, and can be mimicked by exogenous cyclic AMP. Cyclic AMP is thought to affect the phosphorylation of one or more membrane proteins that control permeability[43]. The effect of vasopressin can be blocked by colchicine, a microtubule-disrupting agent. This observation has led to the suggestion that microtubules are involved in the action of vasopressin[43]. Dynein is associated with microtubules, and can be inhibited by vanadate. Perhaps it also plays a part in the vasopressin response[42].

A regulatory role for vanadate?

Several authors have suggested that vanadate may have a regulatory role in mammalian tissues[2, 18, 22, 30]. Small concentrations of vanadium are present, and these would be sufficient to affect the (Na + K)-ATPase, if it were present as vanadate. Regulation could be provided by controlling the vanadyl/vanadate redox reaction. However, all that can be said at present is that there is no evidence for or against this hypothesis. □

The genesis of a void lattice

from Robert W. Cahn

WHEN a metal crystal is irradiated with neutrons or other more massive projectiles then, within certain temperature limits, it acquires a population of microcavities known as 'voids': these arise as a result of the preferential agglomeration of the crystal vacancies which are formed together with interstitial atoms as a result of irradiation. In some metals, voids have been found to arrange themselves in an orderly three-dimensional array – a 'void lattice'. Properly speaking, this is a superlattice, parallel to but coarser than the underlying crystal lattice. The classic instance is the void lattice in irradiated molybdenum, which mimics the body-centred crystal structure of molybdenum itself: but whereas the interatomic distance in the molybdenum lattice is a fraction of a nanometre, neighbouring voids in the void lattice are separated by a distance of 18-27 nm, according to the temperature at which it is created.

A very extensive and effective research effort has developed during the past decade into the genesis and growth of individual voids in the alloys used to contain nuclear fuels and also into the inhibition of void formation; but the origin of the void 'lattice', which is of purely fundamental interest, has only intermittently attracted attention. This is a pity, because the phenomenon is intriguing.

A short paper has just been published in which the known facts concerning void lattice formation in molybdenum are assembled and complemented by some further measurements (Liou, Smith, Wilkes & Kulcinski *J. Nucl. Mater.* **83,** 335; 1979). Molybdenum is the metal in which the existence of a void lattice was originally discovered by Evans in 1971. The new feature which Liou and his collaborators have now established is that voids are originally formed (within a temperature range of about 800-1100 °C) always in a random pattern, and a void lattice is formed only later when a much higher radiation dose has been absorbed and individual voids have grown to a sufficient size. Any theory of the formation of the void lattice therefore has to be based upon the progressive ordering of an initially random dispersion of voids, and indeed such a theory must come to grips with the question of why voids have to grow to a certain size before a lattice can form. Notions such as the nucleation of voids on an ordered pattern of dissolved gas atoms or on an ordered array of dislocation loops (such an array has been observed) are not acceptable.

The stability of a void lattice has been satisfactorily explained by Harwell theorists (for example, Stoneham *J. Phys. F* **1,** 778, 1971). Spherical voids would attract each other at all separations in an elastically isotropic medium, and it is only in an anisotropic medium that a pair of voids can rest stably at a particular separation. Stoneham has proved that a b.c.c. or f.c.c. lattice of voids is stable in molybdenum, though the predicted ratio

---

Robert Cahn is Professor of Materials Science in the University of Sussex.

0028-0836/79/400338-02$01.00

of the separation of voids (in the observed b.c.c. void lattice) to the void diameter is smaller than the values actually observed. Stoneham's theory explains why such a lattice is stable once formed, but not how it is established in the first place.

Liou and his collaborators point out that the formation of a void lattice is analogous to the alignment of precipitate plates on different planes to form a preferred, stable array. This is very commonly observed in alloys formed by spinodal decomposition or by ordering, but had not hitherto been properly analysed. The theoretical basis of this phenomenon has now been rigorously treated by Perovic, Purdy and Brown (*Acta Met.* **27**, 1075; 1979), who calculate the total elastic energy of a regular array of plate-shaped precipitates in a matrix, the precipitates lying on three mutually orthogonal planes. They show that such an array, subject to certain conditions (primarily a low interfacial energy and a large, elastically accommodated misfit between matrix and precipitate) can stabilise at a particular value of the separation of adjacent precipitates, so that further coarsening of the array is inhibited. This presumably is what happens in the formation of a void lattice, though in fact it is not yet known whether a fine void lattice forms first and then coarsens until it becomes stable, or whether the initially disordered voids move about in a kind of Brownian motion until the relative positions of a small group of voids happen to be correct to nucleate a lattice at its proper stable lattice parameter. In the case of a precipitate array, each precipitate plate creates an anisotropic strain field around itself, and an isotropic medium is assumed, for simplicity; whereas in the case of voids, it is only the anisotropy of the medium which allows a void lattice to form at all.

Electron microscopy has shown that an array of precipitates can coarsen progressively by simultaneous dissolution of some portions of a precipitate plate and growth of other portions (Saunderson, Wilkes & Lorimer *Acta Met.* **26**, 1357; 1978), and voids or gas bubbles are known to migrate and merge by a similar mechanism. The growth of voids can be inhibited by small amounts of impurity, which may be fission products such as technetium; the impurity can gather at the void wall and prevent plating out of further vacancies into the void. Because of this, voids may even shrink in the later stages of irradiation (Evans *J. Nucl. Mater.* in the press). In such instances, the eventual shrinkage of the void population is in competition with the formation of a void lattice (which requires a minimum size of void to be attained). What is really required now is simultaneous ion-bombardment and electonmicroscopic observation of the same samples so that the stages of formation of a void lattice can be observed while they actually happen.

Most published photographs of void lattices show them to be distinctly defective (for instance, the photograph on page 338 of Liou's recent paper); the periodicity has a good deal of scatter. It would be interesting to know whether a void lattice, once formed, gradually loses such regularity as it possesses if it is progressively heated; just as a conventional superlattice in, say, Cu_3Au gradually disorders as the alloy is heated. No experiments on annealing of void lattices seem to have been attempted, nor has anyone attempted to improve the regularity of a void lattice by very slow cooling (which is the method used to obtain highly perfect conventional superlattices). There are plainly a number of parallels between void lattices and conventional superlattices which deserve critical examination. □

A spherical structure for allophane

from Ian Smalley

Koji Wada of Kyushu University has produced and collected evidence which strongly suggests that the clay mineral allophane, long regarded as an 'amorphous' constituent of soils, has a unique spherical structure. Although plates and tubes have already been encountered in clay mineralogy, this seems to be the only occurrence of spheres (*Proc. Int. Clay Conf.*, eds Mortland & Farmer, 537; Elsevier, New York, 1978). Taylor and Wilson (*Clays and Clay Miner.* **27**, 261; 1979) describe allophane as consisting of an aluminosilicate core, about 5 nm in diameter, coated to a variable extent with amorphous aluminium hydroxide. The clay surface has hydroxyl and hydronium groups associated with the polymeric hydroxide and the aluminosilicate, and these (by their protonation and deprotonation) are responsible for the *p*H-dependent particle charge developed in aqueous systems. (The nature and properties of variable-charge soils containing allophane will be discussed at the International Society of Soil Science meeting in New Zealand in 1981.)

Allophane usually coexists with imogolite, but the two can be distinguished easily by their shapes, spherical allophane contrasting with tubular imogolite. In 1971 Kitagawa first discovered by high resolution electron microscopy that allophane consists of spherical, hollow unit particles with an average diameter of 5.5 nm. Hemni and Wada (*Am. Miner.* **61**, 379; 1976) observed that similar particles occurred in sixteen allophanic clays, irrespective of their ages and lithological compositions, or the origins of the volcanic ashes and pumices from which the clays were separated. They estimated the external diameter of the particles to range from 3.5 to 5.0 nm and the thickness of the wall to be 1.0 nm or less. The thickness of the wall is broadly consistent with that of a defect kaolin structure.

Wada and Wada (*Clay Miner.* **12**, 289; 1977) determined the density of allophane by float-sink tests in CH_3OH-, CH_3COCH_3-, C_6H_6- and CCl_4-$C_2H_2Br_4$ mixtures as 1.84, 1.94-1.98, 2.35 and 2.35-2.39 g cm^{-3} respectively. Either water molecules only fill the voids of the spherule wall, or all liquid molecules (including $C_2H_2Br_4$) occupy these spaces, the first possibility applying if the wall contains small pores and the second if it contains large pores. It is reasonable to assume that 'defects' in the silicate structure produce such pores or openings in the wall, and the passage of water molecules through these has been confirmed by the ease with which OH ions can be replaced by their deuterium-containing equivalent (OD^-) in allophane.

Wada concludes that the structural formulae for allophanes are in general consistent with the available electron optical and density evidence. The modification of the kaolin layer caused by the size and shape of the unit particles, and by the occurrence of defects, may account for several features of allophanes, especially the absence of both basal and two-dimensional X-ray reflections, the broadness and poor resolution of Si-O-(Al) absorption bands in the 1100-900 cm^{-1} region of the infrared spectra, and the remarkably continuous loss of water with increasing temperature due to dehydration and dehydroxylation. The observed electric charge and acid characteristics of allophanes are also broadly consistent with what is predicted from the structural formule. □

Soil biology and land use

from Clive A. Edwards

A recent symposium* addressed the often neglected subject of the impact of human activities on the soil — the resource on which all plant and animal life depends. Although man's use of the land can often have damaging effects on the soil, work presented at the symposium showed that with care, such effects can be minimised, and careful manipulation of some of the multitide of soil organisms can benefit man by increasing soil fertility, and can help to reclaim polluted land and dispose of an increasing volume of human and animal waste.

There has been much discussion on how

0028-0836/79/400339-02$01.00

pesticides, used in agriculture and in aerial spraying programmes, affect soil ecosystems and a day was devoted to assessing how pesticides affect soil communities and in particular their effects on earthworm and arthropod populations. Work at Rothamsted Experimental Station in England has shown that relatively few pesticides are toxic to earthworms; those that do kill these animals which are important in maintaining soil fertility, include the insecticides chlordane, phorate, parathion and carbofuran, the nematicides D-D, methyl bromide, metham sodium and chloropicrin, and the carbendazim-based fungicides. Work by A.B. Broadbent and A.D. Tomlin, (Canada Agriculture, London, Ontario) and others has shown that pesticides do not have a drastic overall effect on soil arthropod communities but that rather they tend to upset the precarious balance in soil ecosystems, sometimes leading to spectacular upsurges in numbers of those organisms unaffected by a pesticide when their predators were killed; and even, in some instances, new pest problems.

Keen interest was attracted by the work of Roy Hartenstein and his colleagues (College of Environmental Science and Forestry, Syracuse) on the use of earthworms to process human sewage. As restrictions on the dumping of sewage at sea are implemented so waste disposal problems are becoming more serious. The Syracuse workers have found that certain species of earthworms, particularly *Eisenia foetida,* can break down raw sewage into a soil-like material, rich in nutrients and suitable for addition to agricultural land. This process takes about 2 weeks and the commercial development of such a process on a large-scale basis is being investigated and seems likely to succeed. The earthworms produced may be useful as a protein supplement in animal feed. One obstacle to such a process is the rather large concentrations of heavy metals such as lead and cadmium that are often present in sewage, and which would be undesirable in agricultural land from which they might move into edible crops. One group of workers reported investigations into the uptake of heavy metals into earthworm tissues and methods of neutralising the effects of heavy metals on and uptake into crops grown on sewage-amended soil (C. Andersen, Royal Veterinary and Agricultural University, Copenhagen, Denmark).

A third subject that attracted interest was the effects of different kinds of animal wastes added to agricultural land on soil organisms. Workers at University College, Dublin (J.P. Curry & D.C.F. Cotton) have shown that the initial effects of slurries was to decrease earthworm populations in soil to which such wastes had been added drastically but within 7 months populations had recovered and greatly exceeded those in untreated soil. The overall conclusion was that the addition of animal waste to soil tends to favour populations of many soil invertebrates, particularly earthworms, so there seem to be few ecological objections to such a practice.

Surface mining is becoming even more widespread and there is keen interest in the reclamation of such land. The effects of mining iron ore, coal and bauxite on populations of soil organisms were discussed. The general impression was that most mining programmes tend to decrease both species diversity and populations of many soil organisms.

The possibilities of restoring these and other highly disturbed sites to normal biological activity are being investigated by D. Parkinson *et al.* (University of Calgary, Alberta, Canada) by adding different types of surface amendments. They found sewage sludge to be the most effective amendment in terms of plant production and microbial development.

It seems clear from the topics discussed at the symposium that the potential for profitable manipulation of soil organisms to minimise the adverse effects of human activities on soil is considerable and merits much further attention. □

Neurotoxins in Nice

from R. C. Hider

MANY of the most potent animal toxins known are specifically directed against critical membrane proteins of the neuromuscular system. As a result of their specificity and high affinities, biochemists and physiologists have been using many such molecules to great advantage over the past decade. This point was clearly demonstrated at the recent successful EMBO workshop on neurotoxins held in Nice*, where a largely European audience heard presentations on the acetylcholine receptor, the sodium channel and presynaptic membranes.

Postsynaptic toxins

Cobra venom possesses extremely powerful toxins which cause the paralysis of vertebrate skeletal muscle. These small proteins (molecular weight 6,000-7,000) achieve this by binding tightly to the acetylcholine receptor (AChR) which is concentrated at neuromuscular junctions. A toxin-bound receptor is no longer responsive to the natural agonist acetylcholine. The detailed structure of the acetylcholine receptor has been a controversial subject for some years. At the meeting J.P. Changeux (Pasteur Institute) presented compelling evidence that AChR is a hexamer of six identical subunits of molecular weight 40,000. Preparations of this protein have have been successfully incorporated into vesicles and judging from the rapid binding kinetics of a fluorescent agonist, the reconstituted AChR is in a similar state to that found in native membranes. Agonists increase the permeability of these vesicles towards Na ions, the increase being specifically inhibited by α-bungarotoxin (a snake neurotoxin) (Changeux, Heidmann, Popot & Sobel *FEBS Lett.* 105, 181; 1979). A similar mechanism has been established for native AChR *in situ* by electrophysiological experiments. A problem with reconstitution experiments of this type, as pointed out by Changeux, is that the presence of trace quantities of other proteins could be associated with the ion permeability changes. A report from M. Raftery (California Institute of Technology, Pasadena) could have a real bearing on this point because he proposed, on the basis of a large body of evidence, that the receptor is composed of four different proteins (Vandlen, Wu, Eisenach & Raftery, *Biochemistry,* **18,** 1845; 1979). Furthermore he demonstrated that snake neurotoxins bind to two of these components (Raftery *et al. Adv. Cytopharmacol.* **3,** 27; 1979). Both Changeux and Raftery use postsynaptic membranes of the electric organ of *Torpedo* in which AchR constitutes up to 40% of the protein. Significantly, Barnard when isolating AChR from mammalian muscle also finds a single protein of approximately 40,000 molecular weight (Shorr, Dolly & Barnard *Nature* **274,** 283; 1978). Barnard also considers that the ligand recognition unit is possibly an oligomer of six identical units.

If this relatively simple concept proves to be correct then AChR will soon be subjected to classical enzymological studies. Indeed, Changeux presented the N-terminal sequence of the 40K protein (Devillers-Thiery *et al. FEBS Lett.* **104,** 99; 1979) and many advances have been made on the interaction between the snake neurotoxins and this receptor (Maelicke *et al. J. biol. Chem.* **252,** 4811; 1977). The X-ray structure of two such toxins are now established, erabutoxin-b (Kimball *et al.*

---

*EMBO workshop on the Structure and Function of Neurotoxins (24-26 July, 1979) organised by Michelle Lazdunski, Centre de Biochimie, Nice.

0028-0836/79/400340-02$01.00

Biochem. biophys. Res. Comm. **88**, 950; 1979) a-cobratoxin (Walkinshaw *et al. Proc. 6th Int. Symp. on Animal, Plant and Microbiol Toxins* in the press) and suggestions that regions on these molecules mimic agonists (Low, *Handbook exp. Pharmacol.* **52**, 213; 1979) and curarare-like antagonists (Hider, *Adv. Cytopharmac.* **3**, 147; 1979) were presented at the workshop.

As a result of the specificity of these toxins for AChR, they are used for the isolation of the receptor by affinity chromatography and for monitoring AChR levels and turnover rates in muscle and myasthenic patients (Dolly, *Int. Rev. Biochemistry* **26**, 257; 1979).

The sodium channel

Until recently knowledge of the sodium channel has been largely based on electrophysiological data; however, with the discovery of a number of specific toxins this membrane-bound protein has now become susceptible to biochemical study. T. Narahashi (Northwestern University, Chicago) indicated that this large molecular complex appears to be more complicated than AChR, a fact possibly related to its ability to sense membrane potential. Three major toxin-binding sites are being used to characterise the sodium channel — the ionophore site that binds tetrodotoxin (from puffer fish), together with the two peripheral sites, one which opens sodium channels when occupied by the lipophilic toxins, veratridine (a plant alkaloid) and batrachotoxin (from the Colombian frog), and one which blocks sodium inactivation when occupied by polypeptide toxins isolated from sea anemone and scorpion species. An important limitation to the use of lipophilic toxins emerged when W. Ulbricht (Physiologisches Institute, Kiel) warned that the non-specific detergent properties of veratridine begin to predominate above 10^{-4}M.

W.A. Catterall (University of Washington, Seattle) described his two-state model of the channel (*Adv. Cytopharmac.* **3**, 305; 1979) and on the basis of toxin-binding studies suggested a molecular interpretation of the classical Hodgkin-Huxley model of electrical excitation of squid giant axon. Hodgkin and Huxley showed that the activation of sodium channels depends on the value of two voltage-dependant variables (m and H) according to the expression m^3h and Catterall has demonstrated that the ratio of tetrodotoxin and scorpion toxin sites is approximately 3:1 (Catterall & Morrow *Proc. natn. Acad. Sci. U.S.A.* **75**, 218; 1978). This could account for the original m^3h empirical finding. Lazdunski presented recent work on the development of highly radiolabelled derivatives and photoaffinity labels of tetrodotoxin and sea anemone toxin (Lazdunski *et al. Adv. Cytopharmac.* **3**, 353; 1979). It is likely that these compounds will have an important part to play in the elucidation of the sodium channel structure. Indeed the sea anemone toxins may well prove to be suitable for affinity chromatography of the sodium channel. J.C. Fontecilla (University of Alabama) announced the 3-D backbone structure of a scorpion neurotoxin (*Centruroides sculpturatus*), the first to be determined by X-ray crystallography. This important finding, together with the controversy concerning voltage-dependent binding make it likely that the polypeptide toxins will be a focus of attention for the next few years.

Surprisingly, no toxins have yet been found with high affinity for potassium or calcium channels.

Neurotoxic phospholipases

The third major topic of the meeting centred on snake venom phospholipases, and it was fitting that H. Fraenkel-Conrat (University of California, Berkeley) should present a paper as he was the first biochemist to purify a snake toxin (*Berichte* **71**, 1076; 1938). This protein, crotoxin, was isolated from the South American rattle snake and was found to be a phospholipase. His original isolation method is still used today.

Many snake venom phospholipases are extremely potent toxins with a high affinity for neuromuscular junction membranes. P. Strong (University College, London) described the biphasic behaviour of β-bungarotoxin (from the many banded krait) on presynaptic membranes. After an initial binding response which results in a decline of acetylcholine release, a secondary response expressed by an elevated level of release occurs over a 2-hour period. This latter response finally results in the irreversible inhibition of transmitter release. The initial binding response is independent of phospholipase activity, in contrast to the second effect which is completely dependent on such activity (Kelly, von Wedel & Strong *Adv. Cytopharmac.* **3**, 77; 1979). A plausible explanation for this phenomenon is that the toxin initially binds selectively to the plasma membrane and subsequently the phospholipase-active portion of the toxin promotes hydrolysis of the membrane phospholipids. The nature of this specific binding site is not known, although B. Howard (University of California Medical School, Los Angeles) presented evidence to suggest that it would be the Ca translocating system.

One confusing aspect of neurotoxic phospholipases is that many have more than one protein subnit. They all seem to possess a phospholipase unit homologous to porcine pancreatic phospholipase, and this catalytic portion is connected by means of disulphide bonds or electrostatic/hydrophobic interactions to a second nonenzymatic unit. C. Bon (Institut Pasteur, Paris) suggested that the nonenzymatic subunit of crotoxin, which possesses a net negative charge, enhances the pharmacological efficiency of the positively charged phospholipase component by preventing its absorption to nonsaturable binding sites, restricting its binding to specific sites (Bon & Jeng *Adv. Cytopharmac.* **3**, 231; 1979). A similar mechanism has been suggested by Hendon and Tu (*Biochim. biophys. Acta* **578**, 243; 1979). However, this is unlikely to be a general mechanism for neurotoxic phospholipases as, for instance, the net charge of the nonenzymatic portion (B-chain) is 5^+, whereas that of the phospholipase portion (A-chain) is close to zero. An alternative function for the B-chain is implicated for this molecule. Surely it is significant that the B-chain is homologous to the Kunitz-type of proteinase inhibitors (Kondo, Narita & Lee *J. Biochem.* **83**, 101; 1978) and that other such homologues have been isolated from venoms of the Elapidae (Joubert & Strydom *Eur. J. Biochem. 87*, 191; 1978).

It is becoming clear that many of the membrane proteins in excitable tissue undergo conformational changes which can be explained in terms of simple allosteric models. As membrane bound trypsin molecules render lipid bilayers permeable to ions when exposed to typical trypsin substrates it is not difficult to envisage how receptors of the type described by Barnard and Changeux could have evolved from water-soluble enzymes.

Invertebrate respiratory proteins

from E. J. Wood

Because the first X-ray and sequence studies are now appearing, rapid advances can be expected in the next few years in our knowledge of the structure and function of invertebrate respiratory pigments. These proteins, which include the haemocyanins, the erythrocruorins and chlorocruorins, and the haemerythrins (see Hendrickson, *TIBS*, May 1977 for a brief review), were discussed at a recent EMBO workshop in Tours*.

Haemocyanins are non-haem copper proteins which exist as giant aggregates dissolved in the blood of molluscs and arthropods. Mollusc haemocyanins possess very large subunits, and in gastropods, for example, 20 such subunits are assembled in a helical fashion to produce a 9 million molecular weight structure with a 'collar' at each end. The subunits are thought to be single polypeptide chains each consisting of eight

*The EMBO workshop 'Comparative Study and Recent Knowledge on Quaternary Structure and Active Sites of Oxygen Carriers and Related Proteins' was organised by J. & F. Lamy at the University of Tours, France, on 20–24 August.

0028-0836/79/400341-02$01.00

covalently linked oxygen-binding moieties of molecular weight around. 50,000, usually referred to as ‘oxygen binding domains’, in a string. It has proved difficult to determine the exact molecular weight of this basic subunit by physical methods, and SDS-gel electrophoresis does not seem to give reliable values for apparent molecular weights in this range (molecular weight 300,000). Preliminary studies on the biosynthesis of mollusc haemocyanins seem to show that the product of mRNA translation is indeed very large (E. J. Wood, University of Leeds).

From proteolytic digestion studies information on the order of the different types of domain in the string is emerging. (R. Lontie, Katholeike Universiteit, Groningen). Several of the domains are now available in a reasonably pure state and immunological, as well as spectral criteria are used to distinguish them. It seems likely that they differ functionally which may explain certain heterogeneities in functional properties of these haemocyanins.

Arthropod haemocyanins differ from molluscan ones in a number of respects including electron microscopic appearance and their comparatively small subunit polypeptide chains which contain single oxygen-binding sites. Up to seven types of subunits are needed in the assembly of the native molecule in scorpion and *Limulus*, and J. Lamy (University of Tours) has shown how useful immunological techniques are in identifying and quantitating subunits, as well as for helping in the phylogenetic classification of groups of arthropods. Certain subunits share both immunological and assembly correlates in a number of species, and subunit stoichiometry is becoming better understood. Reassembly studies have shown, for example, that for *Eurypelma* haemocyanin, three different types of subunit are needed for the formation of a 16S hexamer, five different for a 24S dodecamer, and all seven for a stable 37S aggregate or ‘24-mer’ (which is the native form). Sequence studies are already showing some homologies between subunits in haemocyanins from *Eurypelma* (a tarantula) and *Androctonus* (a scorpion).

Complete ignorance of the protein structure has so far prevented a description of the changes when O_2 binds to the active site of haemocyanins. A simple model for allostery in haemocyanins was proposed in which Cu—Cu distances affect the strength of O_2 binding and the rate of O_2 dissociation (C. Bonaventura, Duke University Marine Laboratory). Oxygen binding by haemocyanins from both arthropods and molluscs shows certain common features. The discovery that deoxy and carbonmonoxy-haemocyanins (H. Kuiper, University of Rome) have different fluorescence spectra will allow the CO derivatives to be studied in much more detail than has hitherto been possible.

The binding of O_2 by haemocyanin, which is often cooperative, can be described, approximately at least, by a two-state model in which allosteric ligands may bind preferentially to the T or the R state. M. Brouwer (Groningen) has studied the binding of O_2 by *Limulus* haemocyanin and concluded that the ‘switch-over’ in state occurred (mostly) as the fourth O_2 was added. However, binding of the allosteric ligands Cl^- or H^+ can change this. The kinetics of the R-T transition are under investigation and it is suggested that the size of the allosteric unit may be correlated with the rate of the conformational change (M. Brunori, University of Rome).

The relationship between the functional properties of haemocyanins and the haemolymph concentrations of such allosteric ligands (as well as of Ca^{2+} and Mg^{2+} which can control the aggregation state of the molecules) deserves more study than it is receiving at present. The fact that many haemocyanin-containing animals have little or no ability to regulate the ionic composition of their blood may lead to a consequential limitation of O_2-transporting properties, or there may be an important physiological adaptation reflected in the effect of these so-called allosteric effectors on the functional properties of haemocyanin (C. Mangum, Williamsburg).

Several groups are working on the big haemoglobins (or erythrocruorins) of annelids and on the rather similar chlorocruorins. Although the molecules occur in haemolymph as enormous aggregates (molecular weights of up to 4×10^6) they have much smaller subunit polypeptide chains than mollusc haemocyanins. However, general rules about the number of subnits and their sizes have yet to emerge, and it has been difficult to agree on the minimal molecular weight per haem based on chemical determinations. One subunit polypeptide chain from the earthworm, *Lumbricus*, haemoglobin has now been sequenced (Riggs *Fed. Proc.* **38**, 343; 1979) and has 157 residues corresponding to a molecular weight of 17,500. The sequence shows definite homologies with the ß-chain of human haemoglobin. Uncertainties about size and shape of subunits have so far prevented formulation of a definitive model for the native molecular aggregate.

Although the ‘annelid type’ of haemoglobin is common, even being found in a deep-sea tube-dwelling worm from a hydrothermal vent, as reported by N. Terwilliger (Charleston, Oregon), many other types are known. These range from the monomeric (and sometimes dimeric) chironomid haemoglobins, for which there is much sequence information and which are like myoglobin (T. Kleinschmidt, University of Munich), through what might be called medium-sized haemoglobins from *Artemia* (F. De Voeght, Wilrijk, Belgium), branchiopods (E. Ilan, Tel-Aviv) and planorbid snails, to those even bigger than the annelid type such as that from a clam, *Cardita*, reported by R. Terwilliger to have a molecular weight of 8×10^6. In contrast to the annelid type of haemoglobin many of these seem to have very large (presumably multidomain) polypeptide chains.

The third group of invertebrate respiratory pigments comprises the nonhaem iron proteins, the haemerythrins. Very much more is known about these proteins which have only a limited biological occurrence, than about the haemocyanins or invertebrate haemoglobins although admittedly they have a much simpler structure. The coelomic forms (tri, tetra and octomers) have a polypeptide chain of 113 amino acids while the monomeric muscle myohaemerythrin has 118, but there are nevertheless considerable homologies. The coelomic form has four major helical regions (A—D): myohaemerythrin differs in having five extra residues in the C-D corner (W. Hendrickson, Washington). It seems that the polymeric forms possess different subunits, but the differences are minor. The iron site is prominent and resonance Raman studies (D. Shriver, Evanston) have given valuable clues to the mode of oxygen binding. ☐

Crown gall disease

Martin Drummond
ARC Unit of Nitrogen Fixation, University of Sussex, Falmer, Brighton, UK

Agrobacterium tumefaciens *induces tumours in dicotyledonous plants by transferring part of a large bacterial plasmid to the eukaryotic cell. As well as disrupting control of cell division, the transferred DNA determines the synthesis in transformed tissue of novel amino acid compounds which serve as specific substrates for the bacterium. It may prove possible to exploit such DNA transfer for the genetic engineering of higher plants.*

CROWN GALL is a plant tumour caused by *Agrobacterium tumefaciens.* It was first described by Aristotle, first assigned a bacterial aetiology by Smith and Townsend[1], and first proved to be a true oncogenic transformation by White and Braun[2], who showed that crown gall tissue cultured in the absence of the bacterium retained its tumorous properties. The disease occurs in a remarkably wide variety of higher plants[3] but can only be induced in freshly wounded tissue[4]. Oncogenic strains of the bacterium contain a large plasmid, part of which is transferred to the plant cell during oncogenic transformation and maintained there indefinitely[5]; to this extent crown gall resembles the virally induced animal tumours. Transformed tissue is distinguishable by its ability to form an overgrowth when grafted onto a healthy plant, its capacity for growth in tissue culture without added plant hormones[6], and its synthesis of 'opines', unusual derivatives of basic amino acids not found in normal tissue[7-10]. The study of crown gall may help the understanding of carcinogenesis and should be important in elucidating the control of gene expression in higher plants. The possibility of using *Agrobacterium* plasmids as vehicles for genetic engineering in higher plants is also of interest.

Understanding the disease at the molecular level only became possible recently with the discovery that all oncogenic strains of *Agrobacterium* contained large plasmids of about 150–230 kilobases[11], which proved to be essential for tumorigenesis. Hamilton and Fall[12] had shown that one bacterial strain became non-tumorigenic when cultured at 37 °C, and this was shown to be invariably associated with plasmid loss[13-16]. When other *Agrobacterium* plasmids were introduced into the cured strain by conjugation or transformation it recovered oncogenicity, confirming the involvement of the plasmid in oncogenesis[16-21]. Not all large *Agrobacterium* plasmids confer the ability to induce tumours; those that do are designated Ti (tumour-inducing) plasmids. None is smaller than 140 kilobases. So far relatively few genetic markers have been ascribed to them.

The catabolic function of Ti plasmids

The metabolism of opines is a central feature of crown gall disease. Axenic crown gall tissue synthesises opines which can serve as a carbon or nitrogen source for oncogenic agrobacteria. Morel and coworkers noted that the nature of the opine produced is determined not by the host plant but by the bacterium, and is invariably the one catabolised by the inducing strain[22,23]. They interpreted this correlation as evidence for DNA transfer from the bacterium to the plant cell, and suggested that the enzyme catabolising a given opine in the bacterium was identical with that producing it in tumour tissue. In fact two different enzymes are involved, distinguishable both genetically and biochemically[8,24-28]. The enzyme responsible for bacterial catabolism is referred to as an opine oxidase, while that in the plant is termed a synthase. Both are probably plasmid-encoded, although this has not yet been demonstrated unequivocally. With a single exception, the Ti plasmids isolated so far code for the synthesis and breakdown of either octopine or nopaline but not both. The substrate specificity of synthases and oxidases is, however, not exact and both octopine and nopaline tumours contain a characteristic family of opines, comprising analogues of octopine or nopaline (see Fig. 1), which can also support the growth of the inducing strain of *Agrobacterium*[29-34]. Most octopine tumours also contain massive amounts of the recently discovered opine agropine, which is probably the product of a separate synthase, as it is absent from some tumours that do contain octopine (J. L. Firmin, personal communication), and stereochemically is quite unlike octopine[35]. The finding that the plasmid pTi542 codes for agropine metabolism alone bears out this supposition (J. Tempé and J. L. Firmin, personal communications). Three distinct plasmid-encoded permeases exist for nopaline, octopine and agropine[35,36]. The expression of oxidases and permeases by octopine and nopaline determining plasmids has been shown to be coordinately controlled, both enzymes being inducible by their particular substrate[37]. In some strains, the catabolism of arginine, a breakdown product of both octopine and nopaline, is a plasmid-borne trait which is also inducible by the appropriate opine[38].

Ti plasmids promote bacterial conjugation[39,40], and the genes required for their transfer (*tra* functions) are closely associated with opine metabolism, being inducible by the characteristic opine[41,42]. This makes good teleological sense, as in the presence of its substrate the catabolic plasmid will spread rapidly through a mixed population of oncogenic and non-oncogenic bacteria. The three classes of regulatory mutant that can be isolated are most simply explained by postulating separate operons for plasmid transfer and opine catabolism, controlled by the same repressor[43-45].

Tumorigenesis is almost always accompanied by opine synthesis, but as one can isolate mutant plasmids that give tumours failing to produce any opine, such synthesis cannot be necessary for tumour maintenance[45,46]. However, there is some evidence that opines enhance tumour growth[47,48]. Perhaps the

Fig. 1 Structural formulae of opines synthesised by crown gall tumours.

most plausible rationale for the presence of opines in tumour tissue is that they provide a specific ecological niche for the oncogenic bacterium[43]. As only bacteria capable of using opines as carbon and nitrogen sources can exploit the niche, the plasmid thereby generates selection pressure for itself as well as promoting its own transfer through the population. The logical link between opine production and uncontrolled cell division is that the plasmid need only transform a single cell to procure a relatively abundant supply of its opine substrate. It is quite conceivable that other plasmids are also capable of introducing some of their genetic information into eukaryotic cells but go undetected because they lack the more conspicuous oncogenic phenotype.

The opine strategy of the Ti plasmids can be seen as an example of altruism at the molecular level. Altruism is a property of a gene which reduces the darwinian fitness of the individual while enhancing the reproductive potential of the population to which it belongs. T-DNA in the plant cell cannot ultimately enhance its own chances of survival as it must perish with the somatic tissues of the plant, but its expression increases the chances of replication of T-DNA that remains part of the bacterial replicon.

Models of tumorigenesis

A complete description of the crown gall transformation must explain how plasmid DNA enters the plant cell, how it manages to be replicated in the eukaryotic genome and how it exerts its characteristic physiological effects. Much of this is now known, but a full description involves some speculation.

The absolute requirement for a wound for tumorigenesis in the whole plant must be accounted for. Wounding might be necessary to expose bacterial attachment sites on the plant cell surface. A lipopolysaccharide element of the bacterial outer membrane is known to adsorb to specific sites on the plant cell wall[49,50]. An alternative explanation postulates a need for cell division associated with wound healing for successful oncogenesis. This is more consistent with the finding that only if a lesion is inoculated with *Agrobacterium* before the first wave of cell division—up to 2 days after wounding—does oncogenesis proceed as usual[51,52].

The formal resemblance of the plasmid transfer phase of oncogenesis to bacterial conjugation may be reflected at molecular level. Whether the entire Ti plasmid enters the plant cell is not known, but both transformation and conjugation are temperature sensitive with critical temperatures around 30 °C, suggesting that one or more of the oncogenic (*onc*) and transfer functions could be identical[42,53]. However, mapping of the *tra* and *onc* genes in both octopine and nopaline plasmids has not yet revealed any overlap of these functions[45,46].

As well as the genes for plasmid transfer, octopine and nopaline Ti plasmids presumably share at least some of the genetic information involved in oncogenesis. The extent and distribution of DNA sequences conserved on all Ti plasmids is thus relevant to the mechanism of transformation. Octopine plasmids are all very similar in their restriction patterns and

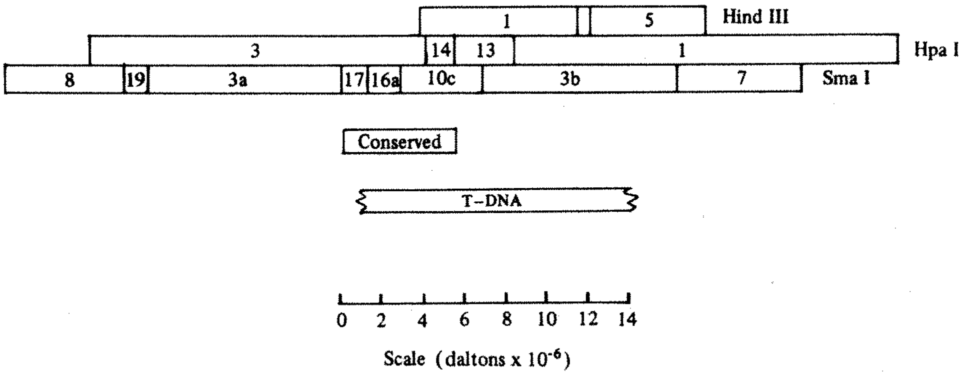

Fig. 2 Section of the physical map of the typical octopine plasmid pTiB6-806 showing fragments detected in tumour tissue (T-DNA) and the DNA which is stringently conserved on all Ti plasmids. Redrawn from Chilton *et al.*[61].

sequence homology[54,55] but are only 20–60% homologous with various nopaline plasmids[56], which themselves form a much more heterogeneous group[52]. Thus if one assumes there has been no divergence in the *onc* functions, only 20% of the information content of the Ti plasmids can be involved in tumorigenesis. This would raise the question of why the plasmids are invariably so large—perhaps the *onc* genes have diverged. It is clear that the opine determinants have done so, maybe to exploit host plants containing different major constituents of a particular opine, and divergence of the *onc* genes in response to host biochemistry is entirely consistent with the plasmid-borne variations in host range which have been observed[57].

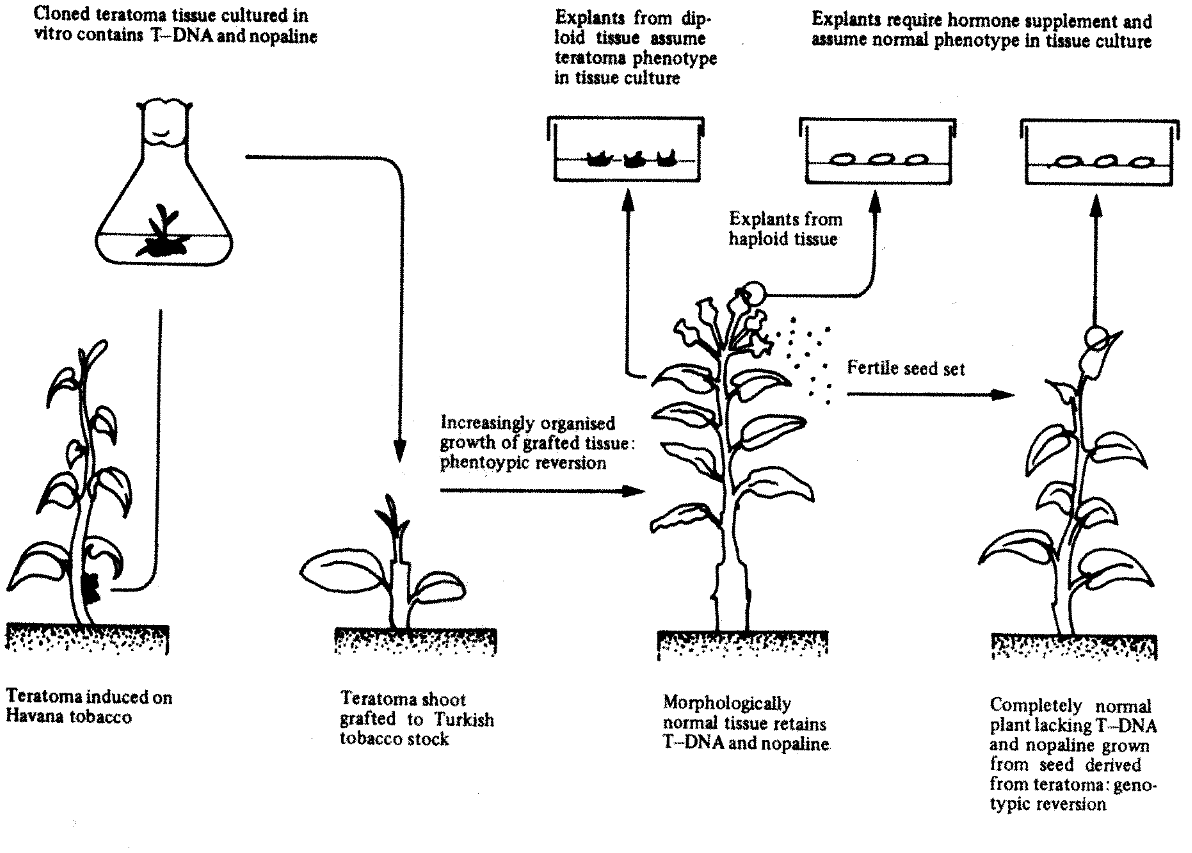
Chilton *et al.*[5] demonstrated the presence of octopine plasmid DNA in a cloned tobacco tumour by using an entire set of plasmid restriction fragments as probes in a series of solution hybridisation experiments. They found $\sim$20 copies per cell of a 6-kilobase segment representing about 3% of the plasmid. Such stretches of plasmid DNA, designated T-DNA, are probably integrated to the plant genome[46]. The mechanism of integration is unknown, but may well differ from that of prokaryotic transposons as stretches of T-DNA derived from a single cell can vary in length[58].

Experiments with restriction fragments containing T-DNA of an octopine plasmid show that the left hand end of the octopine T-DNA and sequences extending as far as its left-hand boundary are highly conserved on all Ti plasmids[59,60] (see Fig. 2). Heteroduplexes of this region show 3–5% base mismatching, markedly lower than the 9–12% mismatching observed for DNA sequences conserved elsewhere on the plasmid[56,60]. Experimental integration of the plasmid RP4 into its area of highly conserved sequences renders a Ti plasmid non-oncogenic[59]. This DNA segment must therefore function in oncogenesis. The greater part of the conserved region is found in all tumour lines that have been examined and is probably sufficient for tumour maintenance[46,58,61]. A 6-kilobase *Sma*I restriction enzyme fragment common to the majority of Ti plasmids encompasses about half of this DNA[60,61] (Fig. 2). The T-DNA to the right of the stringently conserved segment on the octopine plasmid has little or no discernible homology to the corresponding region on the various nopaline plasmids[59,60]. Restriction mapping of insertion mutants of both octopine and nopaline plasmids indicates that this region either contains the opine synthase gene or at least contains the gene that controls opine synthesis by the host[46].

There are two possible ways in which T-DNA could exert its physiological effects. Oncogenesis could result simply from the insertion of T-DNA onto host genes crucial to the control of cell division. The presence of T-DNA in variable copy numbers per cell, and the phenomenon of phenotypic reversion (see below) are, however, easier to accommodate in a model involving a specific oncogenic gene product, analogous to the T-antigen of SV40-transformed rodent cells[62].

At least part of the T-DNA is transcribed in the plant cell. If ^{32}P-labelled RNA from an octopine-producing tumour is hybridised to Ti plasmid restriction fragments that have been transferred to cellulose nitrate paper by Southern's method[63], it binds strongly to *Sma*I fragment 3b, which includes the right-hand boundary of the T-DNA[64]. The labelled RNA is polyadenylated[65] and must include the transcript of the octopine synthase gene if that gene is plasmid encoded. In the nopaline tumour examined by Yang *et al.*[58], there appear to be at least two plasmid RNA species present, indicating that T-DNA sequences other than those coding for nopaline synthase are also transcribed. At least one of these RNA species appears to be from the highly conserved T-DNA, and transcripts from this region have also now been detected in octopine tumours[65,66]. The conserved DNA could encode the putative oncogenic gene product.

Hormone imbalance is strongly implicated in the aetiology of crown gall disease. Cytokinins, which promote cell division, are abundant in crown gall tissue, as are auxins, a class of plant



Cloned teratoma tissue cultured in vitro contains T–DNA and nopaline
Explants from diploid tissue assume teratoma phenotype in tissue culture
Explants require hormone supplement and assume normal phenotype in tissue culture
Explants from haploid tissue

Fig. 3 Reversal of the crown gall transformation.

hormones which stimulate cell enlargement[67,68]. Untransformed tissue cultured *in vitro* does not contain physiologically effective levels of either hormone[6]. Furthermore, plant tumours caused by Black's wound tumour virus as well as those occurring spontaneously in interspecific hybrids of *Nicotiana* also contain abnormally high levels of these hormones[69,70]. Such hormone autotrophy might thus be a sufficient condition for plant neoplasia in general.

Reversion

Crown gall tumours vary considerably in their morphology, some producing recognisable stems or roots while others remain a chaotic mixture of cell types. Ti-plasmid-borne genes determine morphology to some extent[71]. Nopaline tumours typically organise stem primordia on their surfaces, in which case they are referred to as teratomata. When teratoma shoots are grafted to the apex of a normal plant they are forced into rapid growth and gradually regain normal morphology[72,73], a phenomenon termed phenotypic reversion (see Fig. 3). The use of cloned teratoma tissue removes the possibility of selection of untransformed cells, and morphological markers serve to distinguish clearly the scion from the stock. The redifferentiated plant contains T-DNA[58], synthesises nopaline[74], and reverts to the tumour phenotype when explanted into tissue culture[75]. This suggests that phenotypic reversion has an epigenetic basis, in which case studying it should be fruitful in understanding control of gene expression in higher plants.

The crown gall transformation may also be reversed at the genotypic level. Redifferentiated teratoma shoots sometimes flower and set viable seed. Plants grown from this seed lack T-DNA[58], do not synthesise any opine and require a hormone supplement in tissue culture[75]; their recovery is apparently complete. This recovery appears to occur during meiosis, as haploid tissues derived from anther cultures also fail to synthesise nopaline and show the normal hormone requirement in culture. Such complete recovery occurs only very rarely in diploid tissues[75]. Loss of T-DNA at meiosis could occur in one of three ways: (1) haploid progeny carrying T-DNA are not viable (the integration of T-DNA could cause recessive mutations); (2) chromosomes bearing such insertions are specifically excluded from the progeny; or (3) there exists some machinery in the meiotic cell which can excise extraneous material from the genome (controlling elements in maize survive meiosis, however). None of these possibilities can be excluded at present.

Genetic engineering with Ti plasmids

It should be possible to use Ti plasmids as vectors to insert a chosen DNA sequence into the genome of any dicotyledonous plant. The phenotypic reversion described above shows that this need not disrupt normal differentiation, but genotypic reversion may limit the technique to plants that can be propagated vegetatively. The difficulties involved in introducing a bacterial gene into a crop plant and having it expressed appropriately are daunting. For example, simply inserting *nif* (nitrogen fixation) genes into the potato genome would be useless, as to be of value their expression must be subjected to eukaryotic control and some system devised to protect the nitrogenase from oxygen poisoning. More immediate applications of the technique may involve restoring to their original genome plant DNA sequences which have been modified *in vitro*, say to increase the lysine content of a storage protein.

The first step in any such project would be to identify and probably isolate the DNA sequence encoding the desired trait. This must then be inserted into the T-DNA. To introduce foreign DNA sequences into a prokaryotic cloning vehicle it is sufficient simply to cut the vehicle into one or two pieces with a suitable restriction enzyme, then reassemble it with the 'passenger' in place. The Ti plasmids, however, being so large, are extensively cleaved by the available restriction enzymes, and the chances of reassembling a functional whole with the passenger in the desired site are remote. This difficulty could possibly be obviated by deleting unnecessary segments of the plasmid or by modifying restriction sites where cleavage is not wanted. An alternative would be to use a restriction enzyme such as *Hph*I that cleaves at some distance from its recognition site[76]; the 'sticky' ends generated at each cut are then unique, which guarantees accurate reassembly of the plasmid. The passenger could be inserted into an isolated fragment containing T-DNA before the whole is reassembled.

However, it might be possible to avoid manipulating DNA *in vitro* altogether. Schell and his collaborators allowed the transposable element Tn7, which codes for streptomycin resistance, to hop into the T-DNA of a nopaline plasmid. The modified T-DNA was then introduced into the tobacco genome, where it was detected using Southern's[63] technique. The chosen genetic trait is unlikely to be a transposable element, of course, but one could attempt to make it so. Some transposons have been shown to be flanked by insertion sequences[77,78] which may well be sufficient to promote transposition[79]. It should be possible to construct a bacterial plasmid having an insertion sequence at either end of the DNA sequence one wishes to transpose into the T-DNA.

Whether or not it proves possible to exploit the peculiar properties of the Ti plasmids for genetic engineering, work on crown gall disease will continue to make an important contribution to our understanding of the molecular biology of higher plants.

I thank Brigid Hogan, Mary-Dell Chilton, Jacques Tempé, Jeff Schell, Frank Cannon and John Cairns for criticism of the manuscript.

Crust of oceanic affinity in Iceland

I. L. Gibson Iceland Research Drilling Project (Edited by I. L. Gibson*)
Department of Land Resource Science, University of Guelph, Ontario, Canada

Evidence for subsidence of at least 2 km during crustal formation and the absence of an increase in minor intrusion density with depth in the lower 2 km are the major results of the field study of a 3-km vertical section of Icelandic crust.

DURING the past six years major efforts have been made to determine the structure, composition and mode of formation of the oceanic crust. Such investigations are, however, severely hampered by the great depth of water in the ocean basins and the difficulty of deep drilling in the basaltic layer of the crust. An alternative approach is to study elevated mid-ocean ridge segments such as Iceland. Although not underlain by typical oceanic crust, Iceland forms a part of the Reykjanes–Kolbeinsey section of the Mid-Atlantic Ridge and contains a record of eruptive processes at a spreading axis. It is also well exposed and easily accessible for study. A detailed investigation of the Icelandic crust should provide important information on the processes of crustal construction, hydrothermal alteration and magmatic evolution of one part of the Mid-Atlantic Ridge.

The first results from a continuously cored, 1,919-m deep borehole drilled in eastern Iceland, forming the lower part of an intensely sampled 3-km section, are reported here. The section is entirely within seismic layer 2. Overall core recovery was 99.7%. Hole diameter was 7.6 cm down to 1,350 m, then 6.0 cm to the bottom.

The structure of eastern Iceland is relatively simple and consists of a thick succession of deeply dissected Neogene flood basalts which dip gently westwards towards and beneath the Neovolcanic zone of North-east Iceland. Walker[1] showed that the lava pile consists of a series of overlapping groups of flows that thin progressively up-dip. Lava dip decreases from 7–10° near sea level to 2–3° near the 1,000-m summit level. The nature of the regional zeolite grade metamorphism suggests that the basalt pile had a finite limit about 1.5 km above sea level where the intensity of dyke injection approached zero and the lavas were horizontal and unzeolitised.

The drill site (lat 65° 01′ N, long 14° 21′ W) is located near sea level, 8 km east of the centre of the Thingmuli central volcano, at the head of Reydarfjordur in a geologically and geophysically well known area[2–6], where crustal dilation by north–south basaltic dykes is 10% (Fig. 1). Final site selection was on the basis of unpublished gravity data (G. Palmason, personal communication) which were used to identify a location within a large area of anomalously high temperature gradient ($\sim$80 °C km^{-1} (ref. 7)) where the regional gravity anomaly was of average value.

Lava stratigraphy

The combined exposed and drill-hole 3-km section consists of subaerial lava flows, with thin intercalated pyroclastic and volcaniclastic sedimentary horizons, all cut by minor intrusions (Fig. 2*a*, *b*). In the drilled sequence minor intrusions comprise 40% of the core and cut out large sections of flow stratigraphy.

Six minor faults with displacements up to 50 m are present in the exposed section and similar faults probably cut the drilled succession, although no obvious stratigraphic repetitions were observed. Regional mapping has indicated the absence of major faults in the area[2].

All thickness values quoted for both the exposed and drilled sequences are vertical thicknesses. The deviation of the hole from the vertical was measured by acid tests at 100-m intervals and was usually much less than the maximum value of 7°.

The observed dip in the cliff section varied from 2° at 1,000 m elevation to 10–14° at sea level. Dips measured in the drill core are scattered but suggest that the observed increase with depth continues until a value of about 20° is reached at about 500 m below sea level, below which little further increase occurs.

Examination of the drill core in the field showed that the flows are predominantly subaerial fine-grained aphyric tholeiitic lavas characterised by reddened rubbly flow tops and massive to weakly flow-banded grey-green interiors, corresponding to the tholeiites and basaltic andesites of Walker[2]. Notable exceptions include a 12-m thick Icelandite flow from 1,083 to 1,095 m (unit 185.5) and a 31-m thick welded ash-flow tuff sequence from 920 to 951 m (units 157.2, 161.1 and 162.1).

Fig. 1 Map and section showing the geology in the vicinity of the IRDP Reydarfjordur drill site.

It is not possible to correlate the major part of the drill-hole succession with the observed up-dip lava sequences exposed on the north and south sides of Reydarfjordur. This was unexpected in view of the regular nature of the exposed geological structure but several features may explain this situation. First, minor intrusions may cut out some key horizons. Second, an unknown amount of down-dip thickening of the lava units may occur—a simple extrapolation of the rate of thickening observed in the sub-aerial section may not be applicable to the lower part of the section. Third, gradual but large-scale lateral changes in the lava stratigraphy may exist.

Aside from difficulties in making specific correlations between the drill hole and exposed, up-dip sections, a striking general result is the paucity of olivine-bearing basalts in the 3-km crustal section, in contrast with a frequency of occurrence of 23% (ref. 2) in the Reydarfjordur succession as a whole. This paucity of olivine-bearing rocks may relate to the early manifestation of the Thingmuli and Breiddalur centres, which erupted over-saturated basaltic lavas and silicic 'differentiates'.

Minor intrusions

Steeply dipping north–south basaltic dykes that are approximately normal to the flows are found at all levels in the exposed section. Dyke density increases notably towards sea level reaching a dilation value of 10%, measured over a 1.6-km transect normal to the swarm, through the drill site. In spite of the obvious drawback in sampling near-vertical rock units with a vertical drill hole, the excellent core recovery allows dykes to be identified in the core on the basis of their chilled contacts, their essentially non-vesicular character, and frequently by their large vertical extent. An example of the multiple dykes which occur is the particularly thick complex of dykes between 528 m and 586 m (units 90.1, 90.2, 90.3, 90.4, 91.2, 92.1, 94.1 and 94.2). There is a broad distribution of intrusive contact angles in the core. Over 40% of these contact angles lie between 55° and 75°. The remainder are rather uniformly distributed over all other angles. In total, 98 minor intrusions constitute 40% of the drill core; however, 11 of these, with vertical extent of greater than 20 m, account for over half of this percentage. The seven minor intrusions in the uppermost 400 m of the drill core comprise five isolated examples and one two-component multiple dyke of 110 m vertical extent (units 10.1 and 17.1, 63 to 173 m). Below 400 m the distribution of minor intrusions is markedly non-uniform. Minor intrusions are concentrated in three intervals each of about 300 m vertical extent separated by comparable intervals in which intrusions are generally much less common (Fig. 2*b*).

Preliminary observations suggest that the minor intrusions are generally less altered than the intervening flows. Thin-section studies indicate that at least some of the dykes in the core are olivine bearing and thus may not be directly related to the lavas of the drill core which are mainly olivine free.

Some of the minor intrusions occurring below 400 m in the drill core are almost certainly gently dipping sheets of a type characteristic of the deeper parts of many Icelandic Tertiary and Quaternary volcanic centres. There is no demonstrable increase in the proportion of minor intrusions as a whole with depth in the drill core (0–500 m, 34%; 500–1,000 m, 42%; 1,000–1,500 m, 45%; 1,500–1,919 m, 39%) or in the proportion of thick, apparently steeply dipping dykes.

Secondary mineralisation

A generally progressive increase of alteration with depth in the section characterises the lavas but is not obvious in the dykes. The topmost flows in the exposed section are unzeolitised. Zeolites appear lower in the exposed section (Fig. 2*a*). In general laumontite is absent in the exposed section, but is found in the Skessa tuff, a silicic ash-flow 100 m above the drill site.

All the flows in the drill core are variably altered, with macroscopic secondary minerals abundantly developed in the brecciated and vesicular flow tops and bottoms. Laumontite is dominant in the upper 1,000 m of the core. A shift from smectite to chlorite dominated assemblages occurs at the 200–300-m depth. Epidote first becomes very common at 1,200 m, where it occurs in both amygdales and veins and in the groundmass of the basalts. From 1,200 m to the bottom of the core at 1,919 m epidote is patchily distributed with alternating rich and deficient sequences. Calcite, various forms of silica and 'celadonite' are common secondary minerals throughout the drill core and various parts of the exposed section. Of particular interest are grossular garnet at dyke contacts at 425 and 1,166 m and anhydrite at 1,055 m.

The alteration pattern of the lavas in the drill core is very similar to that found in other drilled sections in the Tertiary formations of Iceland[7].

Clearly the secondary mineralisation took place at a very much higher temperature than that measured in the hole at present. Based on data from drill holes in the active volcanic zone of Iceland, the lower boundary for the formation of laumontite seems to be about 110 °C and that for epidote about

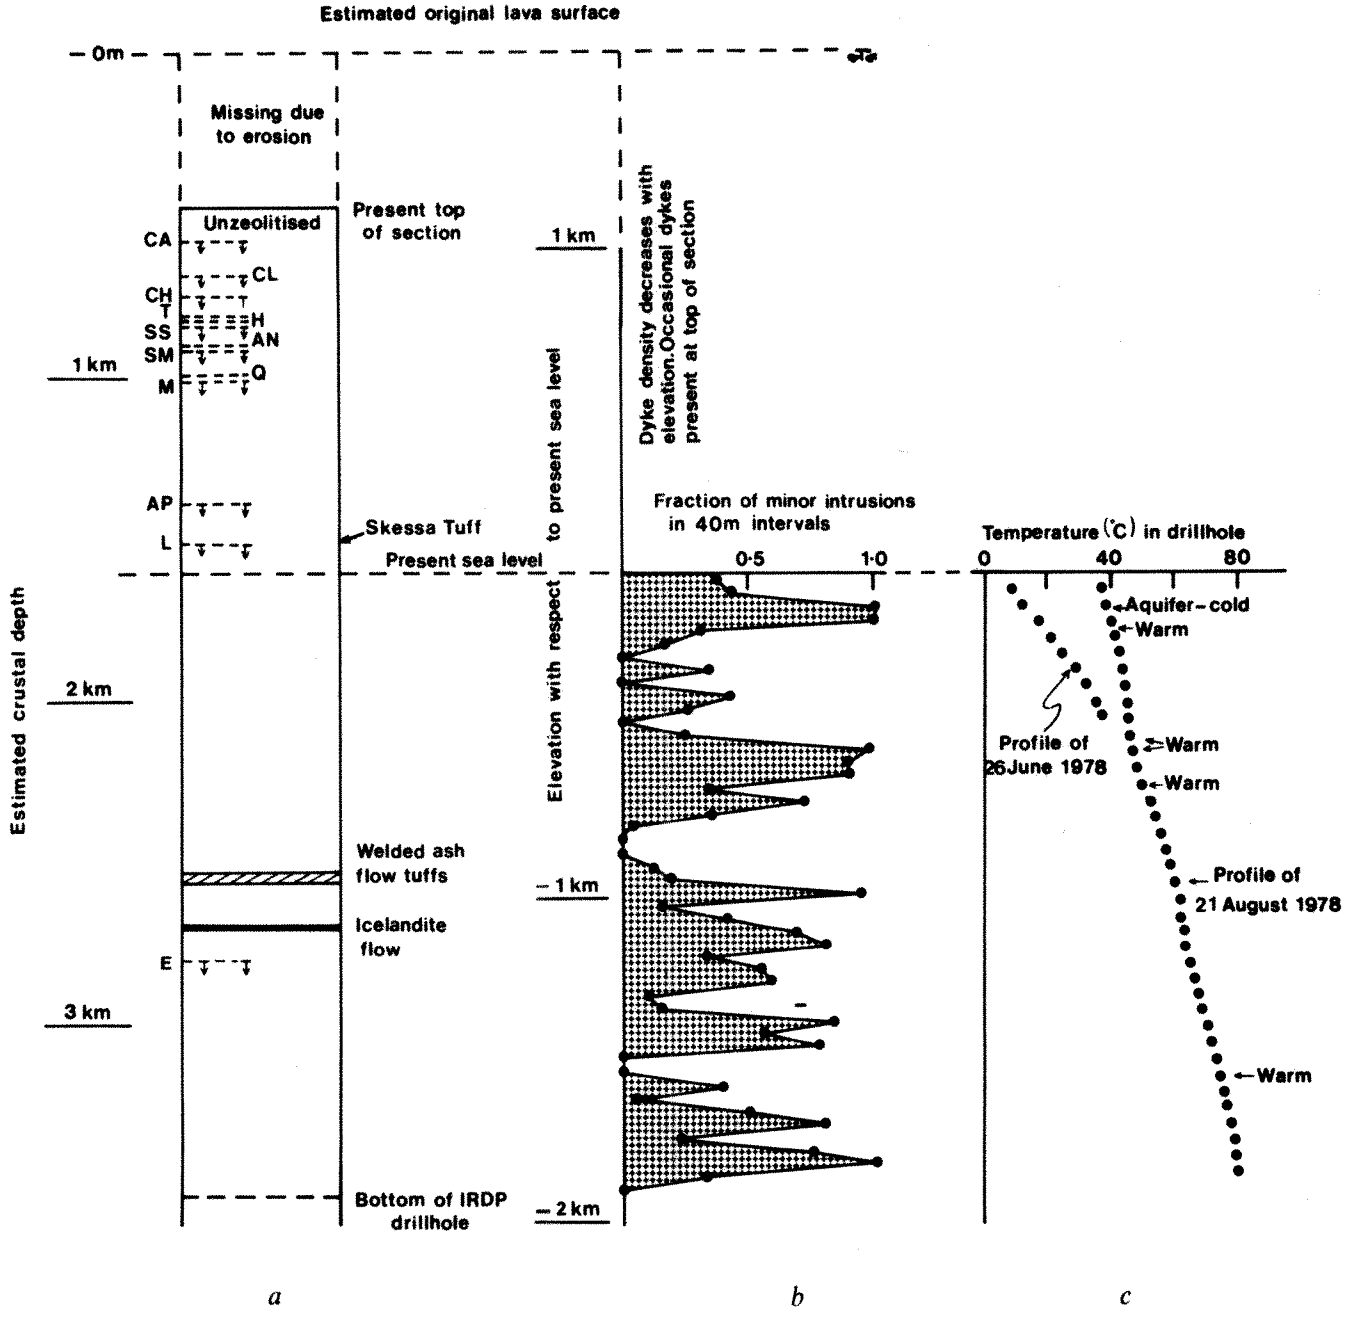

Fig. 2 Profiles through the 3-km Icelandic crustal section. *a*, Marker horizons and highest occurrence of key secondary minerals are indicated by a dashed line and downward pointing arrows. CA, calcite; CL, clay; CH, chabazite; T, thomsonite; H, heulandite; SS, stilbite; AN, analcite; SM, scolecite–mesolite; Q, quartz; M, mordenite; AP, apophyllite; L, laumontite; and E, epidote. *b*, Fraction of minor intrusions in each 40 m depth interval. *c*, Temperature profiles before and after penetration of the series of artesian warm water aquifers between 517 m and 628 m depth.

230 °C (ref. 8). Assuming an original surface 1,500 m above sea level and a linear temperature gradient, the figures suggest the existence of a temperature gradient of close to 85 °C km^{-1} during the formation of the secondary mineralisation.

Magnetic properties

Measurements of initial susceptibility and polarity of natural remanence magnetism (NRM) were obtained for the lower 2 km of the section. Susceptibility values were obtained every 50 cm or less, correction being made for the size and cylindrical shape of the core. Although remanence cleaning is necessary to define the polarity succession reliably, natural remanence polarity measurements may be of some value in locating the section with respect to the known time–magnetic polarity sequence.

The most important feature of the susceptibility measurements is a strong and regular overall decrease with depth for the flows from a mean value of 40×10^{-4} e.m.u. cm^{-3} for the 0–480-m depth interval to 14×10^{-4} e.m.u. cm^{-3} for the 1,440–1,919-m interval. Linear extrapolation of this trend in mean values for the lavas suggests that susceptibility would reach zero value at 2,600 m below sea level or at just over 4 km beneath the original surface of the lava pile. In contrast, no depth trend in minor intrusion susceptibility occurs, with mean values for 480-m depth intervals varying irregularly from 26 to 31×10^{-4} e.m.u. cm^{-3}. Susceptibility typically varies little within minor intrusions, except where fractures or intervals of high permeability occur. In contrast, strong within-unit variation is common for flows, with minima at boundaries and one or two interior maxima. In a general sense, susceptibility variation follows the alteration pattern: the downhole decrease in flow values matches the increase in alteration grade from a laumontite stage to an epidote stage while the minima at flow boundaries correspond to maximum secondary mineral development in these porous regions.

The relatively high average values, and lack of a trend with depth in minor intrusion susceptibility, corresponds with the apparent low alteration state of these units, and may also be indicative of their much younger age. Decomposition of the iron–titanium oxides resulting from zeolite and epidote grade metamorphism is likely to explain reduction of susceptibility in the flows.

Above 1,230 m depth only normal NRM polarity occurs. Reverse NRM polarities, including shallow inclinations, occur mainly within the following depth intervals: 1,445–1,635, 1,690–1,730 and 1,882–1,919 m. Multiple changes of NRM polarity within units have frequently been found in the lower bore-hole section.

At this stage the extended normal polarity zone of the upper half of the core apparently correlates with magnetic anomaly 5 (magnetic epoch 9).

Geothermal measurements

Temperature profiles in the drill hole were obtained weekly, in each case after a 24-h cessation of drilling. Initial water samples were taken from four levels several days after the termination of drilling, but these showed signs of mixing with drilling fluid and the sampling will be repeated. A temperature profile measured when the well was 445 m deep (Fig. 2*c*) showed an approximately linear thermal gradient of about 80 °C km^{-1}. Between 517 m and 628 m a series of prominent artesian aquifers with water at 48 °C were penetrated. These aquifers were tested when the hole was at a depth of 650 m and produced a net flow of 0.8 l s^{-1}. Several smaller aquifers were penetrated at greater depths. Flow of water from the prominent aquifers led to a major change in thermal regime in the hole (Fig. 2*c*); the temperature gradient below these aquifers is much lower.

The site was located within an area of anomalously high surface temperature gradient, and results from the drill hole strongly suggest that this anomalous area is the result of shallow regional geothermal flow of water at moderate temperatures.

Geophysical logging

Extensive geophysical logging of the drill hole was carried out by the Icelandic National Energy Authority with natural γ-ray, neutron–neutron porosity, γ–γ density, caliper, self-potential, 0.4 m and 1.6 m normal resistivity, temperature, differential temperature, sonic velocity and differential magnetic permeability recorded. In the cased central part of the hole (580–1,350 m) self-potential, resistivity and differential permeability could not be recorded. Sonic velocity was recorded from the surface to 1,350 m depth.

Preliminary results show a very pronounced relationship between the physical and lithological parameters. An example is the high resistivity contrast between the massive centres of lava flows and the brecciated or rubbly margins. Dykes and intrusions are also characterised by high resistivity. Relatively few, but prominent, anomalies in the natural γ-ray log are recorded. The sequence of welded ash-flow tuffs between 920 and 951 m depth is characterised by high natural radioactivity and low γ–γ density. Thin breccia layers can be identified in the neutron–neutron porosity log as well as in the γ–γ density log.

Crustal seismology

Two crustal seismic experiments were carried out in association with the drilling project, one by a group from Leningrad and the other by a group from the University of Washington and the Scripps Institution of Oceanography. The results from these experiments are still being interpreted.

Discussion

Although intensive laboratory studies of the 3-km section are continuing, some important points are already evident. Perhaps the most striking feature is the continuously sub-aerial nature of the lavas implying that at least 2 km of subsidence has occurred. No pillowed basalts were found. The absence of marked erosional features in the exposed upper part of the section suggests that the lavas were erupted in an area of low relief at most a few hundred metres above sea level and the implication is that subsidence probably took place concomitant with the volcanism at a rate of at least 1 km Myr^{-1}. Subsidence on this scale is implied in many of the models for crustal growth in Iceland (see ref. 9) and is observed elsewhere where active, volcanic zones occur in areas of oceanic crust[10–12].

The progressive change in the nature of the alteration with depth is also striking. The intensity of metamorphism in the lavas increases gradually, but in detail relatively fresh rocks interfinger with more altered horizons. If the layer 2/layer 3 boundary is fundamentally a metamorphic transition then the present study suggests that such a transition may take place over a distance of the order of 1 km.

The combination of the olivine-bearing nature of some of the minor intrusions, the magnetic properties, and the relative freshness of most of them may imply that they were not feeders for the bulk of the lava succession. The possibility that the dykes are related to the Breiddalur centre[13], 20 km to the south, and that they have been injected laterally northwards in the manner that is presently being observed in the Krafla volcano in north Iceland[14] must be considered.

This article is based on work at the Icelandic Research Drilling Project (IRDP) laboratory in Reydarfjordur Iceland and elsewhere by the following: U. Bleil, N. Christensen, J. Clark, J. Delaney, R. Emmermann, I. Fridleifsson, I. L. Gibson, N. Gruver, J. M. Hall, L. Hall, K. Hattori, J. Helgason, D. Johnson, H. P. Johnson, G. Kimmich, J. Kirkpatrick, H. Kristmannsdottir, S. Levi, B. T. R. Lewis, J. McClain, J. McHegan, C. Peterson, G. Pritchard, P. Robinson, F. Rummel, H. Schmincke, G. Schönharting, S. W. Smith, V. Stefansson, W. H. Thomson, O. Thorpe, R. Thorpe, S. van Waggoner, L. Viereck, R. Wilkens, G. Wörner, M. Zentilli. A number of the above provided extensive notes on which some sections of this article were based.

Financial support for IRDP field operations was from the Icelandic Energy Fund, NSERC (Strategic Grant Program in Ocean Sciences, grant G0063) and Dalhousie University (Canda), NERC (UK), NSF (grant no. EAR 78-11725) and ONR (grant no. N000-14-78-C-0389) (US), BMFT (grant ET 4248) and DFG (grant SCHM 250/21) (West Germany), SNF (Denmark) and NATO. The National Research Council of Iceland granted permission for the work to be carried out in Iceland. We thank the people of Reydarfjordur for their considerable assistance.

Isolation, cloning and sequence analysis of the cDNA for the α-subunit of human chorionic gonadotropin

John C. Fiddes & Howard M. Goodman

Howard Hughes Medical Institute Laboratory, Department of Biochemistry and Biophysics, University of California, San Francisco, California 94143

A 621-base pair fragment of the cDNA for the α-subunit of human chorionic gonadotropin has been isolated by cloning in a plasmid vector, and the complete nucleotide sequence determined. The entire coding region, including the 24-amino acid pre-sequence and most of the untranslated regions, are present in the fragment.

HUMAN chorionic gonadotropin (HCG) is a glycoprotein hormone which is synthesised by the syncytiotrophoblast cells of the placenta. It functions during pregnancy to convey a signal from the placenta to the corpus luteum which results in the maintenance of the corpus luteum and an increased synthesis of steroid hormones (for reviews see refs 1, 2). Certain malignant tumours, not necessarily of placental tissue, also synthesise HCG[3,4]. Detection of HCG by radioimmunoassay is therefore diagnostic of pregnancy or the presence of a tumour[5].

In addition to its medical importance, HCG is an interesting system for studying temporal gene regulation during development. Levels of HCG in the urine can be detected a few days after implantation of the fertilised ovum[6]. Production of the hormone reaches a peak level of about 1 μg ml^{-1} in the plasma at 10–12 weeks and then declines considerably during the second and third trimesters[7]. It is not understood what controls this rise and decline of HCG synthesis during pregnancy nor why such large amounts of the hormone are synthesised towards the end of the first trimester.

The three anterior pituitary hormones, luteinising hormone (LH), follicle-stimulating hormone (FSH) and thyroid-stimulating hormone (TSH), are closely related to HCG in that all four hormones are glycosylated and have a dimeric structure comprising an α-and a β-subunit[1,2,8]. The amino acid sequence of the α-subunit, which is 92 residues long, seems to be identical in all four hormones[9–15], whereas the amino acid sequences of the β-subunits vary[10,16–22]. The β-subunits confer the biological specificity to the hormones[1,2]. Sequence homologies exist between the β-subunits, and to a lesser extent between the β-subunits and the α-subunit, leading to the proposal that all five subunits evolved from a common ancestral gene[23].

The glycoprotein hormones therefore provide an interesting group of structurally related sequences which have been studied extensively in terms of their protein chemistry and biological functions but for which very limited information is available about their mRNA and genomic organisation. This report describes the isolation, by cloning in pBR322, of a 621-base pair cDNA fragment synthesised from first-trimester placental polyadenylated mRNA. The fragment contains the coding sequences for the 92 amino acids of the α-subunit of HCG, the 24 amino acid pre-sequence and most of the 5′- and 3′-untranslated regions.

In vitro translation of placental RNA

Full-term and first-trimester placental mRNA has been analysed by *in vitro* translation and cDNA synthesis to determine whether the higher levels of HCG produced by first-trimester placentae are reflected by higher amounts of cDNA than occur in full-term placentae.

The major protein product synthesised by full-term placentae is the hormone human chorionic somatomammotropin (HCS). Full-term placental polyadenylated mRNA has been analysed previously by wheat-germ translation and immunoprecipitation of the translation products with an antiserum against HCS[24]. The predominant translational product was a protein of molecular weight (MW) 24,000, which contained tryptic peptides in common with HCS[25], and which was precipitated specifically by the antiserum and thus identified as the pre-form of HCS. A similar approach has been used here to analyse first-trimester placental polyadenylated mRNA, which should be enriched for HCG-specific mRNA. The *in vitro* translation products have been compared with those obtained from full-term mRNA, which should have much less HCG-specific mRNA.

DNA was extracted from human placenta obtained either at term (from caesarian sections) or from first-trimester abortions (about 10–12 weeks). The RNA samples were translated in a wheat-germ cell-free translation system with ^{35}S-methionine and the products fractionated on an SDS–15% polyacrylamide gel (Fig. 1). Full-term placental RNA (lane 3) shows the major product of MW 24,000 which has been identified as pre-HCS[24,25]. This product is still observed with first-trimester placental RNA (lane 2) but at a considerably lower level. This is consistent with the observations made by Boime *et al.*[25] and by Chatterjee *et al.*[31], who have also compared the synthesis of HCS by full-term and first-trimester RNA in cell-free translation systems.

The major proteins synthesised *in vitro* by first-trimester RNA (lane 2) have estimated MWs of 13,000 and 16,000 and are only observed in trace quantities with full-term RNA (lane 3). These products are candidates for the pre-forms of the α- and β-subunits of HCG, respectively, as the respective MWs of the

0028–0836/79/400351—06$01.00

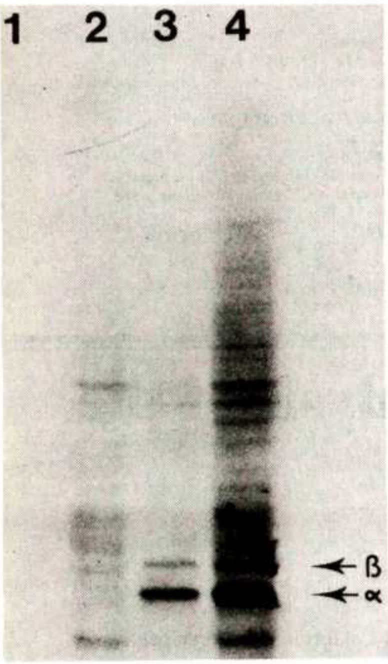

Fig. 1 Wheat-germ translation products of full-term and first-trimester placental mRNA. Human placental tissue was obtained from either caesarian sections or first-trimester abortions. The tissue was washed in cold saline to remove blood, frozen quickly in liquid nitrogen and stored at −70 °C. RNA was prepared by methods similar to those described previously[24,26]. Ten grammes of frozen tissue were added to 100 ml of 5 M guanidine thiocyanate in 50 mM Tris-Cl, *p*H 7.5, 10 mM EDTA and 5% 2-mercaptoethanol and homogenised in a Tissumizer (Tekmar) until all the tissue was dispersed. The solution was centrifuged at 10,000 r.p.m. for 10 min and the supernatant adjusted to 2% Sarkosyl and heated at 65 °C for 2 min. Caesium chloride was then added (0.1 g ml^{-1} of solution) and the resulting solution was layered over 6-ml cushions of half-saturated CsCl in 10 mM EDTA in SW 27 cellulose nitrate tubes. Centrifugation was at 25,000 r.p.m. for 16 h at 20 °C. The RNA pellet was dissolved in 5 mM EDTA, 0.5% Sarkosyl and 5% 2-mercaptoethanol, extracted with phenol and chloroform and precipitated with ethanol. Usually, 0.5–1 mg of RNA were obtained per g of tissue. The RNA was then passed over an oligo(dT)-cellulose column[27] to enrich for the polyadenylated fraction. RNA samples were translated by wheat-germ cell-free extracts[28,29]. Reaction mixtures (40 μl) contained 20 mM HEPES buffer, *p*H 7.6, 2 mM dithiothreitol, 0.1 mM spermidine, 80 mM K acetate, 1 mM Mg acetate, 1 mM ATP, 0.02 mM GTP, 8 mM creatine phosphate, 40 μg ml^{-1} creatine phosphokinase, ~25–50 μCi ^{35}S-methionine (400–900 Ci mmol^{-1}, Amersham), 50 μM each of the other 19 amino acids, 16 μl of wheat-germ extract and 0.5–1.0 μg polyadenylated RNA. Incubation was at 28 °C for 1 h. The products were analysed on an SDS–15% polyacrylamide slab gel[30] and the dried gel autoradiographed. Lane 1, endogenous wheat-germ products; lane 2, first-trimester placental RNA; lane 3, full-time placental RNA. The proposed identifications of the translational products, as discussed in the text, are indicated.

mature forms of these proteins, without glycosylations, are 10,200 and 15,500 (refs 9, 10, 16–18).

The wheat-germ products synthesised in the presence of first-trimester RNA were immunoprecipitated by an antiserum directed against mature HCG and the products fractioned on an SDS–15% polyacrylamide gel (Fig. 2). The translational products generated by first-trimester RNA are shown in lane 4 and the immunoprecipitated products in lane 3. Both the 13,000 and 16,000 MW products seem to precipitate specifically, supporting their identification as pre-forms of the α- and β-subunits of HCG, respectively. In general, however, the immunoprecipitation reactions were inefficient and unreliable. The weak antibody–antigen reaction is presumably related to the fact that the antibody was raised against the mature glycosylated dimeric form of HCG and not against the non-glycosylated pre-forms of the individual subunits which are produced in cell-free translation systems. A small amount of pre-HCS is also precipitated in this reaction (lane 3) but this seems to be the result of a specific reaction between HCS and the formaldehyde-treated *Staphylococcus aureus* cells used to collect the antigen–antibody complex, because it also precipitates in the absence of antibody but in the presence of the *S. aureus* cells.

The data presented here are consistent with other results. It is reasonable to expect a greater quantity of α- than β-specific mRNA as there is an excess amount of free α-subunit over free β-subunit in plasma[33]. Also, Landefeld *et al.*[34] have shown that the major translational product from first-trimester RNA has tryptic peptides in common with the native α-subunit. Daniels-McQueen *et al.*[35] and Chatterjee *et al.*[31,36] have observed lower levels of β-subunit synthesis than α-subunit synthesis in cell-free systems and have demonstrated a greater amount of synthesis of these subunits with first-trimester than with full-term RNA.

Restriction enzyme analysis of placental cDNA

Discrete restriction endonuclease fragments can be generated from heterogeneous cDNA if that cDNA contains a reasonably enriched species. This approach has been used to clone fragments of human growth hormone, HCS, rat growth hormone and rat insulin cDNAs[37–40]. The differences in translational activities observed between first-trimester and full-term human placental RNA should therefore also be observed in the restriction enzyme fragments generated from cDNA synthesised from these two sources of mRNA. Comparison of the two cDNA fragment patterns should allow identification of fragments in first-trimester cDNA which probably correspond to either α- or β-HCG and thus facilitate cloning of these cDNA species.

Double-stranded cDNA was synthesised from polyadenylated RNA obtained from both first-trimester and full-term placentae and was restricted with either *Alu*I or *Hpa*II. The products were fractionated by electrophoresis on a 5% polyacrylamide gel (Fig. 3). With both enzymes a specific band pattern is observed which varies with the RNA used to generate the cDNA. The 340-base pair fragment obtained when full-term cDNA is digested with *Alu*I (lane 1) is known from sequence analysis to be present in HCS cDNA[38] and is only observed at a very low level in first-trimester cDNA (lane 2). In contrast, *Alu*I digestion of first-trimester cDNA (lane 2) generates fragments

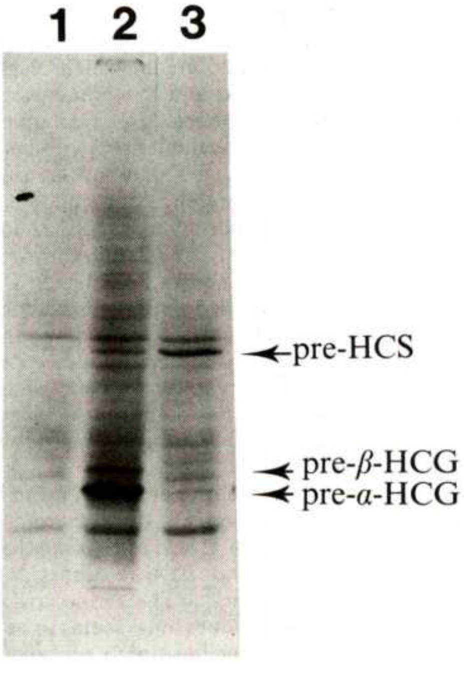

Fig. 2 Immunoprecipitation of wheat-germ products by HCG antiserum. The wheat-germ translation products generated by first-term placental RNA (Fig. 1) were immunoprecipitated by an antiserum directed against native HCG and the antigen–antibody complex collected by formaldehyde-treated *S. aureus* cells[29,32]. The products were fractionated on an SDS–15% polyacrylamide gel[30] and visualised by autoradiography of the dried gel. Lane 1, immunoprecipitation of endogeneous wheat-germ products; lane 2, endogenous wheat-germ translation products; lane 3, immunoprecipitation of wheat-germ translation products directed by first-trimester placental polyadenylated RNA; lane 4, wheat-germ products of first-trimester placental polyadenylated RNA. The proposed identifications of the pre-forms of the α- and β-subunits of HCG are indicated.

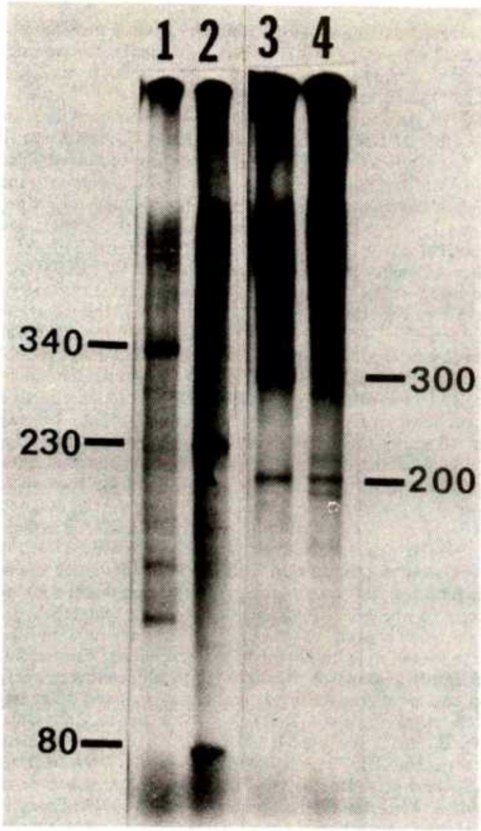

Fig. 3 Restriction enzyme analysis of double-stranded cDNA made from polyadenylated RNA extracted from both full-term and first-trimester human placentae. The methods used for synthesis of double-stranded cDNA were similar to those described previously[37,39,41]. For preparative syntheses, ~20 μg polyadenylated RNA were incubated in 200 μl reactions containing 50 mM Tris-Cl, *p*H 8.3, 10 mM $MgCl_2$, 20 mM KCl, 10 mM 2-mercaptoethanol, 500 μM each of dATP, dCTP, dGTP and dTTP (one [α-^{32}P]-nucleoside triphosphate at specific activity 500 c.p.m. ^{32}P per pmol), 20 ng μl^{-1} oligo$(dT)_{12-18}$ and 200 units reverse transcriptase. Incubation was at 42 °C for 30 min and was stopped by the addition of EDTA to 10 mM. After extraction with phenol and chloroform and precipitation by ethanol, the material was fractionated on a 25 × 0.25 cm column of Sephadex G-50 in 1 mM Tris-Cl, *p*H 7.4, and 0.01 mM EDTA. The leading peak was collected (~200 μl) and adjusted to 0.3 M NaOH and 10 mM EDTA and incubated overnight at room temperature. Following neutralisation with sodium acetate, *p*H 5.5, and ethanol precipitation, the second strand was synthesised in a 50-μl reaction containing the same buffer as described above, 500 μM each of dATP, dGTP and dTTP and 100 μM dCTP (10,000 c.p.m. ^{32}P per pmol) (considerably higher specific activities were used for analytical reactions) and 50 units reverse transcriptase. Incubation was at 42 °C for 90 min. For subsequent restriction enzyme analysis the reaction was stopped by heating to 65 °C for 10 min and the appropriate restriction enzymes added directly. Alternatively, the reaction products were fractionated as described above on a Sephadex G-50 column and the peak evaporated to dryness before proceeding to treatment with S_1 nuclease (see Fig. 4 legend). Lane 1, *Alu*I digest of full-term placental cDNA; lane 2, *ALu*I digest of first-trimester placental cDNA; lane 3, *Hpa*II digest of full-term placental cDNA; lane 4, *Hpa*II digest of first-trimester placental cDNA. Sizes are in base pairs.

of 230 and 80 base pairs that are not observed in full-term cDNA. The enzyme *Hpa*II also generates different fragments from full-term and first-trimester cDNAs (lanes 3, 4). It is reasonable to assume that the fragments specific to first-trimester cDNA correspond to either α- or β-HCG cDNA.

Cloning of the cDNA for the α-subunit of HCG

The comparisons of the wheat-germ translation products and the cDNAs synthesised from full-term and first-trimester placental polyadenylated mRNAs suggest that it should be possible to clone the HCG cDNA species from first-trimester material without any further enrichment procedures.

Double-stranded cDNA was synthesised by reverse transcriptase from 20 μg of first-trimester polyadenylated mRNA[37,39,41] (Figs 3, 4). Yields of about 5% and 25% were obtained on the first- and second-strand syntheses, respectively. An aliquot of the double-stranded cDNA was electrophoresed on a 5% polyacrylamide gel and the products visualised by autoradiography (Fig. 4, lane 2). A prominent band corresponding to a chain length of about 700 base pairs can be seen above the heterogeneous cDNA background. This species was also observed, but with the expected slower mobility, in the single-stranded cDNA (Fig. 4, lane 1). Presumably, this species corresponds to a full-length cDNA for either the α- or β-subunit of HCG, as 700 base pairs has sufficient coding capacity for either subunit plus untranslated regions, but not for the two together. Cleavage of the double-stranded cDNA with the enzyme *Hin*dIII generates a new band (about 630 base pairs) plus a residual low level of the 700-base pair band (Fig. 4, lane 4). As this was observed reproducibly it is not believed to be the result of partial digestion. Instead, it is interpreted to mean that the initial undigested 700-base pair band contains two cDNA species, presumably corresponding to the α- and β-subunits of HCG, and that the major species of cDNA contains a *Hin*dIII site about 50 base pairs from one end.

The full-length cDNA in the size range 600–750 pairs was then cloned into the unique *Hin*dIII site of pBR322 using synthetic *Hin*dIII linkers as described in Fig. 4 legend. Small plasmid DNA preparations were made from the 22 recombinants obtained in the transformation and analysed by restriction enzyme digestion. The enzymes *Pst*I and *Xba*I were used because first-trimester cDNA cleaved with these enzymes produces specific fragments, about 230 base pairs long in the case of *Xba*I and about 380 and 170 base pairs long in the case of *Pst*I (Fig. 4, lanes 7, 8). These fragments are presumably diagnostic of HCG cDNA and can be readily detected, as the plasmid pBR322 contains a single *Pst*I cleavage site and no *Xba*I cleavage site[44]. One recombinant was obtained; it had a *Hin*dIII insert about 620 base pairs long which when digested with *Xba*I gave fragments of 400 and 220 base pairs and when digested with *Pst*I gave fragments 370, 170 and 80 base pairs long. In addition, this 620-base pair *Hin*dIII fragment contains *Alu*I and *Hpa*II fragments consistent with those observed in first-trimester cDNA (Fig. 3). This recombinant cDNA clone was thus considered a candidate for the α-subunit of HCG because it corresponds to the major cDNA species. No candidates for β-HCG cDNA have been obtained.

DNA sequence analysis of α-HCG cDNA

DNA sequencing was used to show that the *Hin*dIII fragment codes for the α-subunit of HCG and is 621 bases long. Initial identification of the recombinant, designated α-HCG/pBR322, was by a modification of the sequencing technique described by Maat and Smith[45] for sequencing 5′-terminally labelled DNA fragments by the chain termination method (A. J. H. Smith, personal communication). The end-labelled DNA fragments were incubated with DNA polymerase I (Klenow modification) and a single dideoxynucleoside triphosphate, and the products were loaded directly onto a DNA sequencing gel (see Fig. 5 legend). This method results in the introduction of the chain terminators into the double-stranded DNA, presumably at the sites of nicks in the DNA caused by the contaminating DNase in DNA polymerase I preparations. This was found to be a particularly rapid method for analysing potential recombinants, but difficulties were encountered in obtaining accurate sequences where there were stretches of a single nucleotide.

The complete nucleotide sequence of the recombinant was obtained following transfer of the 621-base pair *Hin*dIII fragment to the single-stranded DNA phage vector M13 mp5. Standard chain termination methods were used[46,48] and, where possible, sequences were obtained on both strands, but in all cases the results were confirmed by additional primings. The complete 621-base pair sequence is presented in Fig. 5.

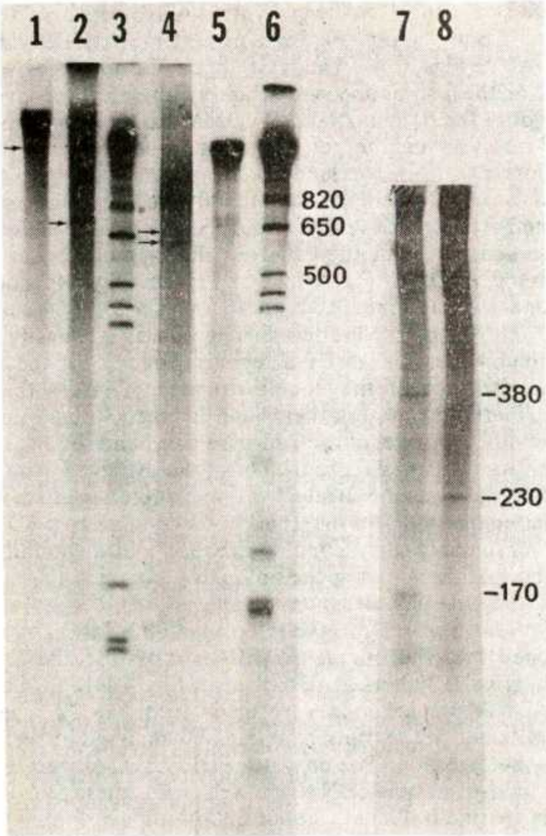

Fig. 4 Synthesis and cloning of first-trimester cDNA. The methods used for cloning the cDNA using *Hin*dIII linkers were similar to those described elsewhere[37,39]. Synthesis of double-stranded cDNA from 20 μg polyadenylated RNA was as described in Fig. 3 legend. After fractionation by Sephadex G-50, the double-stranded cDNA was incubated with 5 units of S_1 nuclease in 300 mM NaCl, 30 mM Na acetate, *p*H 4.5, and 3 mM $ZnCl_2$ at 42 °C for 5 min (refs 37, 41). The reaction was stopped by the addition of EDTA to 10 mM and neutralised with Tris base. Following extraction with phenol and chloroform, the products were fractionated over a Sephadex G-50 column (Fig. 3) and the peak fraction evaporated to dryness. The DNA was then incubated in a 25-μl reaction with 50 mM Tris-Cl, *p*H 7.5, 10 mM $MgCl_2$, 10 mM 2-mercaptoethanol, 25 μM each of dATP, dCTP, dGTP and dTTP and 1 unit of DNA polymerase I (Klenow fragment, Boehringer) at 12 °C for 15 min. The reaction was adjusted to 50 μl in the same buffer with 1 mM ATP and 12 μg kinase-treated [5'-^{32}P]-labelled *Hin*dIII decanucleotide linkers (2×10^6 c.p.m. total) and incubated with 0.3 units T4 DNA ligase and 2.5 units T4 RNA ligase (Biolabs) at 12 °C overnight. After heating the reaction to 65 °C for 10 min, 50 units *Hin*dIII were added directly and the reaction was incubated at 37 °C for 2 h. Aliquots of the reaction were assayed at all stages by electrophoresis on 5% polyacrylamide gels and autoradiography of the dried gels. Following extraction with phenol and chloroform, the cDNA, with cohesive *Hin*dIII ends, was fractionated on a preparative 5% polyacrylamide gel and fragments in the size range 600–750 base pairs recovered by electrophoretic elution. The cDNA was then ligated to 100 ng *Hin*dIII-cleaved, alkaline phosphatase-treated pBR322 (refs 37, 39, 42) and used to transform *E. coli* χ1776 as described elsewhere[43]. Transformation and subsequent growth were carried out in a P3 facility in compliance with the NIH Guidelines for Recombinant DNA Research. Twenty-two colonies were obtained which were resistant to 20 μg ml^{-1} ampicillin and sensitive to 20 μg ml^{-1} tetracycline. The recombinants contained *Hin*dIII inserts of the appropriate size and were analysed by restriction enzyme digestion, in particular with *Pst*I and *Xba*I (see text). Lane 1, full-length single-strand cDNA; lane 2, full-length double-strand cDNA; lane 3, *Hpa*II digest of M13 DNA; lane 4, double-stranded cDNA digested with *Hin*dIII; lane 5, double-stranded cDNA digested with nuclease S_1; lane 6, as lane 3; lane 7, *Pst*I digestion of double-stranded cDNA; lane 8, *Xba*I digestion of double-stranded cDNA. Lanes 1–4, 5–6 and 7, 8 are from separate gels. Autoradiographs were made from dried 5% polyacrylamide gels. Sizes are in base pairs.

Fig. 5 Nucleotide sequence of the 621-nucleotide-long cDNA fragment coding for the α-subunit of HCG. The amino acid sequence of the 92-residue-long mature protein is shown as well as the 24-residue pre-sequence deduced from the cDNA sequence. Nucleotides are numbered below the sequence and amino acids above the sequence. The restriction endonuclease sites used in the sequence analysis are indicated. DNA from α-HCG/pBR322 was cleaved at the unique *Xba*I site, labelled with [γ-^{32}P]ATP by polynucleotide kinase and then digested with *Hin*dIII. The 400-base pair *Hin*dIII–*Xba*I fragment was isolated and divided into four separate 5-μl reactions each containing 6 mM Tris-Cl, *p*H 7.4, 6 mM $MgCl_2$, 1 mM dithiothreitol, 0.2 mM of a single dideoxynucleoside triphosphate and 1 unit DNA polymerase I (Klenow modification) and incubated at 37 °C for 1 h (ref. 45 and A. J. H. Smith, personal communication). The products were analysed directly on thin sequencing gels[46]. After the 621-base pair fragment had been shown by this method to code for α-HCG, it was transferred to the unique *Hin*dIII site of the single-stranded filamentous DNA phage vector M13 mp5. This phage is a derivative of M13 mp2 (ref. 47); its transformation and growth (J. Messing, unpublished results) were done in a P3 facility in accordance with the NIH Guidelines for Recombinant DNA Research. Initially, the host strain 71/18 was used but has lately been replaced by JM101 (J. Messing, unpublished results). Both the coding and non-coding strands of the cDNA were inserted separately into the viral strand of the phage DNA and were used as templates for DNA sequencing reactions by the chain termination method[48]. Restriction enzyme fragments for use as primers were obtained from α-HCG/pBR322.

The finding that the α- and β-subunits of the glycoprotein hormones are synthesised from separate polyadenylated mRNA species agrees with the deduction made by Daniels-McQueen *et al.*[35], who observed that the α- and β-translational activities for HCG sedimented at different positions in sucrose gradients.

The amino acid sequence for the 92 codons of the mature form of α-HCG as determined previously[9,10] corresponds to that predicted from the DNA sequence (Fig. 5) with the exception of codon 15. Morgan *et al.*[10] identified this position as aspartic acid whereas Bellisario *et al.*[9] did not distinguish between aspartic acid or asparagine. DNA sequence analysis shows that the correct amino acid is asparagine. This assignment agrees with the sequences reported for the α-subunits of human LH and FSH[11,12,14] which are probably identical to α-HCG. The sequences reported for the α-subunits of HCG[9,10] and human FSH[14] have the sequence Cys–Ser at positions 84 and 85, whereas this order is reserved in the reported sequence for human α-LH[11]. The DNA sequence analysis of α-HCG cDNA supports the former identification of this dipeptide. N-terminal heterogeneity has been reported for the α-subunits of human glycoprotein hormones involving the first three amino acids and was assumed to be the result of proteolytic cleavage. The identification of the coding sequence for this region supports this assumption.

A pre-sequence of 24 amino acids can be predicted from the cDNA sequence (Fig. 5) and has the same characteristic hydrophobic stretches observed in other pre-sequences (see ref. 49). This sequence agrees with the preliminary results of Boime *et al.*[50], who have identified a pre-sequence of 24 amino acids for the α-subunit of HCG and have located the positions of the Ala, Phe and Leu residues.

The coding region ends with the termination codon UAA and is followed by 220 bases to the *Hin*dIII site. This restriction enzyme site is not the result of a linker ligation but corresponds to the natural *Hin*dIII site observed in the cDNA. Approximately 50 bases of the 3′-terminal region of the cDNA are thus absent from the clone, including the sequence AAUAAA which is characteristic of all polyadenylated eukaryotic mRNA species[51]. Fifty bases of the 5′-untranslated region are present in the clone before the *Hin*dIII linker molecule. The sequence AAGGAG located at positions −10 to −5 before the initiator AUG shows perfect complementarity with the 3′-end of *Escherichia coli* 16S rRNA and is thus similar to a prokaryotic ribosome binding site[52].

The codon usage observed with the α-subunit of HCG, including the pre-sequence, is shown in Fig. 6. Of the 10 serine codons, nine are of the form UCN and only one is AGPy; all four arginine codons are of the form AGPu and none are CGN.

The similarity in amino acid sequence among all four α-subunits for human CG, LH, FSH and TSH suggests that they are coded for by a single gene. To test this, the 621-base pair fragment was labelled with ^{32}P and used as a probe to hybridise to endonuclease-digested human placental DNA by the method of Southern[53] (Fig. 7). With three enzymes, *Eco*RI (lane 1), *Bgl*II (lane 5) and *Pvu*II (lane 6), single hybridising bands are observed. The *Eco*RI fragment is about 6.5 kilobases long. These results suggest the existence of either a single gene or multiple copies arranged in tandem within the 6.5-kilobase fragment.

Fig. 6 Codon usage of α-HCG mRNA.

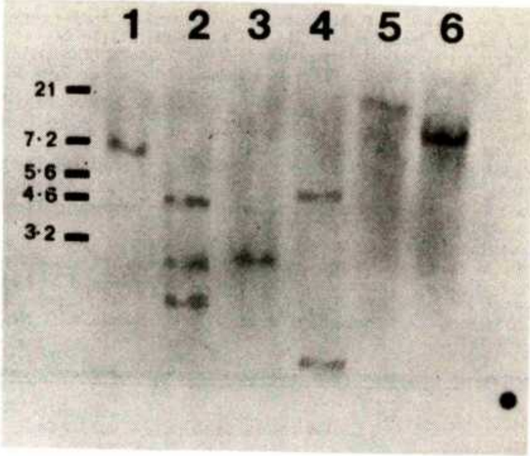

Fig. 7 Autoradiograph of a filter hybridisation between restriction endonuclease-digested human placental DNA, fractionated on a 1% agarose gel, and ^{32}P-labelled, cloned α-HCG cDNA. The filter hybridisation method of Southern[53] was used as described previously[54]. Lane 1, *Eco*RI; lane 2, *Xba*I; lane 3, *Pst*I; lane 4, *Hin*dIII; lane 5, *Bgl*II; lane 6, *Pvu*II. The positions and sizes in kilobase pairs of the fragments produced by an *Eco*RI digest of wild-type bacteriophage λ DNA are shown.

J.C.F. is the recipient of a postdoctoral fellowship from the Anna Fuller Foundation. H.M.G. is an investigator of the Howard Hughes Medical Institute. The work was supported by a grant (no. CA14026) to H.M.G. We thank P. Seeburg, A. Ullrich, J. Martial, J. Roberts, J. Messing and J. Ramachandran for advice and materials, members of the Department of Obstetrics and Gynecology at UCSF for assistance in obtaining placental material, P. Burnett (of Lilly) for use of facilities, F. M. DeNoto for assistance in preparing plasmid and phage DNA, C. Bisaillon for typing the manuscript and H. Martinez for use of computer programs for analysing DNA sequences. Avian myloblastosis virus reverse transcriptase was from the NCI.

Note added in proof: A more accurate estimate of the size of the hybridising *Eco*RI fragment is 5.0 kilobases.

Diffusion of the highest energy cosmic rays from Virgo

J. Wdowczyk

Institute of Nuclear Research, Lodz, Poland

A. W. Wolfendale

Department of Physics, University of Durham, UK

The origin of the predominant particle component of cosmic rays is still undecided although at 'low' energies ($E \sim 10^9$–10^{10} eV) γ-ray data provide circumstantial evidence in favour of an origin in galactic sources[1]. The galactic magnetic field deflects trajectories, at least until about 10^{18} eV, and almost completely destroys any relationship between the directions from which cosmic rays arrive and the directions to their sources, making the elucidation of origins a problem. Above 10^{18} eV, if the primary cosmic rays are mainly protons, as would be expected and as is claimed[3], then the absence of large anisotropies associated with the galactic plane strongly suggests that the particles are from extragalactic sources. If they are extragalactic and their sources are distributed widely in the Universe then, because of interactions between the protons and the photons of the 2.7 K relict radiation, the observed spectrum should steepen considerably above several times 10^{19} eV. However, the opposite appears to be happening: the measured spectrum flattens above about 10^{19} eV (refs 4–6) (see Fig. 2). Several suggestions have been made to account for this paradox, in each case the idea being to generate in extragalactic space a production spectrum which is so 'flat' that even after energy losses are taken into account, the resulting spectrum at the Earth has the characteristic observed flattening (for example ref. 7). Here we put forward an alternative model where the observed spectral shape arises in a rather natural way, being due to propagation characteristics in the local supercluster, the bulk of the very energetic particles having originated in its central region.

Many studies have been made of the diffusion of cosmic rays within the Galaxy but little attention has been given to the possibility of propagation in extragalactic space being by diffusive rather than rectilinear motion. This is due to lack of knowledge of the topography of the magnetic field in space. Recent measurements of X-ray emission from clusters of galaxies (some of which seems to be due to thermal bremsstrahlung from hot intergalactic gas) make us believe, however, that significant magnetic fields exist. For example, if some measure of equipartition exists between field energy ($B^2/8\pi$) and kinetic energy of gas clouds ($\rho v^2/2$) then the likely gas densities of $\approx 10^{-4}$ atoms cm^{-3} in clusters indicate fields of $\approx 10^{-8}$ G.

A necessary parameter for particle diffusion is the cell length over which the field can be regarded as uniform—rough arguments suggest that a dimension of the order of a few galactic diameters (say 0.1 Mpc) might be reasonable. These arguments are: (1) A likely source of at least some of the cluster field is clouds of gas containing cosmic rays which are forced out of the galaxy when supernovae explode. Such clouds, with closed field loops, would presumably have dimensions of a few kpc on emergence from the galaxy and would expand at greater distances. (2) Within the galaxy the cell length seems to be about one hundredth of the mean linear dimension of the galaxy. One hundredth of the characteristic dimension of the supercluster would correspond to a few hundred kpc. There is, of course, no certainty about the magnitude of the cell length adopted, but it does seem as though a value within a factor 10 either way of 100 kpc is likely.

The Larmor radius of a proton of energy E_{20} (in units of 10^{20} eV) in a field of 10^{-8} G is $E_{20}.10$ Mpc, so diffusion might be expected to be very important for particles from all extragalactic sources at energies below $\simeq 10^{18}$ eV and for particles from sources within some tens of Mpc with energy below 10^{20} eV or so. Above a few times 10^{21} eV there will be rectilinear propagation from sources within tens of Mpc.

The attenuation length for protons on the microwave background is well known. This length, λ, equals the distance to the centre of Virgo (19 Mpc) at $E_0 \simeq 3\times10^{20}$ eV. The next 'large' cluster, Pegasus I, is at 65 Mpc, for which $E_0 \simeq 1.3\times10^{20}$ eV. If the sources of particles of energy $\approx 10^{20}$ eV are only present in cluster centres, then these particles will only arrive from Virgo, particles from further afield having had insufficient time to travel to Earth. It is this feature of depressing cosmic rays from sources beyond Virgo that distinguishes the present model from previous ones (for example, the supercluster enhancement models of Strong *et al.*[8] and Stecker[9,10]).

We now consider a model in which particles diffuse from the centre of Virgo and are removed after a mean time T determined by the Hubble time or the attenuation time (λ/c), whichever is the shorter.

Calculations have been made for a variety of forms of the dependence of the diffusion coefficient on energy $D(E)$. General arguments dictate that D should be a function of E but the dependence is not known. For galactic cosmic rays the change of slope of the spectrum at $\sim 3\times10^{15}$ eV is often interpreted as due to a change of the form of $D(E)$ from $D(E)=$

0028-0836/79/400356—02$01.00

constant below 3×10^{15} eV to $D(E)\not\propto E^{0.5}$ above. The latter is our preferred choice for the supercluster.

The flux of cosmic rays at a distance x from a continuously emitting source can be shown to be

$$n(x)=\frac{qcT}{2\pi^2x^3}w\phi(\sqrt{2w}),$$

where $w=x^2/4DT$ and

$$\phi(y)=\frac{1}{\sqrt{2\pi}}\int_y^\infty \exp-\frac{s^2}{2}\,ds \tag{1}$$

where q is the rate of emission of particles from the source. It is assumed that D is only a slowly varying function of E. The expression is valid only at energies significantly below E_0 where $D(E_0)=cx/3$; at significantly higher energies straight line propagation occurs and $n(x)=q/4\pi x^2$ (the flux being collimated from the source). For very low energies, where $\phi(y)$ is given by the recurrence formula,

$$n(x)\rightarrow\frac{cq}{8\pi^{5/2}}\frac{1}{x^2D}\sqrt{DT}\exp-\frac{x^2}{4DT} \tag{2}$$

Figure 1 shows $n(x)$ for two forms of $D(E)$. The curves are normalised at 10^{19} eV. Above 10^{20} eV there is increasing inaccuracy as straight line propagation is approached and our estimate is only approximate. The forms chosen for $D(E)$ were $D(E)\propto E^{1/2}$ and $D(E)\propto E$—the galactic situation seems to require the former and we regard this as the preferred expectation for supercluster propagation, at least above 10^{18} eV.

Figure 2 shows the prediction for $D(E)\propto E^{1/2}$ normalised to the experimental results at 10^{19} eV. The required production spectrum is

$$q(E)=7.4\times10^{24}\left(\frac{E(\mathrm{GeV})}{10^{10}}\right)^{-2.44}\ \mathrm{s^{-1}\,GeV^{-1}} \tag{3}$$

and the diffusion coefficient is

$$D(E)=5\times10^{33}\left(\frac{E(\mathrm{GeV})}{10^{10}}\right)^{1/2}\ \mathrm{cm^2\,s^{-1}} \tag{4}$$

There is quite good agreement between prediction and observation, at least above about 5×10^{17} eV (in this model, particles of lower energy would come from galactic sources).

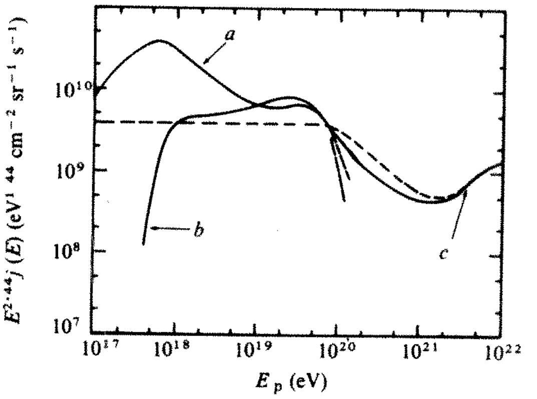

Fig. 1 Spectra of protons expected from the centre of Virgo. Predictions for alternative choices of $D(E)$ are indicated. Chain lines above 10^{20} eV are predictions for the diffusion model in this region; there must be a transition to the situation for straight line propagation (c), which must be reached above about 2×10^{21} eV, and the full line represents an approximate estimate. If there were no extragalactic magnetic field (--- $B_{\mathrm{EG}}=0$) the contribution from Virgo alone would follow the dashed line indicated. The drop above 10^{20} eV is due to interactions with the 2.7 K radiation. An energy-independent $D(E)$ would not give the required upturn in the spectrum. a, $D=5\times10^{33}\sqrt{E(\mathrm{GeV})/10^{10}}\ \mathrm{cm^2\,s^{-1}}$. b, $D=5\times10^{33}(E(\mathrm{GeV})/10^{10})\ \mathrm{cm^2\,s^{-1}}$.

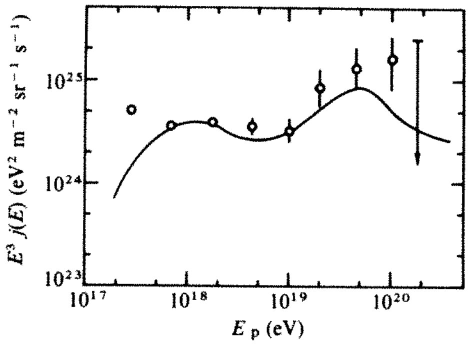

Fig. 2 Spectra of extragalactic protons (from Virgo) predicted using the form of $D(E)\propto E^{1/2}$ given in Fig. 1. The experimental intensities come from a summary of all the experimental measurements[4–6].

The numerical values for the parameters can be examined to see if they are reasonable. $D(E)$ gives $\lambda\simeq150$ kpc at $E=10^{19}$ eV and this is of the expected order of magnitude. The production spectrum, however, gives a high output; extrapolating $q(E)$ back to 1 GeV gives a total rate of energy production of $\sim7\times10^{46}\ \mathrm{erg\,s^{-1}}$, compared with $\sim6\times10^{40}\ \mathrm{erg\,s^{-1}}$ for the Galaxy. This ratio of 10^6 is much bigger than the ratio of 500 or so which pertains at radio wavelengths[11]. A further difference is that the spectral slope ($\gamma=2.44$) is less than that associated with galactic particles below 10^{15} eV. However, a number of points can be made in support of the argument: (1) The exponent of the production spectrum for galactic particles is probably significantly smaller than the measured value of 2.6 (and nearer 'our' 2.44) because of the likelihood of the cosmic ray lifetime falling with increasing energy. (2) Other galaxies near Virgo may also be contributing. More important, with the likelihood of a different acceleration mode for M87, the exponent could be different at very low energies and the total energy produced consequently much smaller.

An indication that the yield of particles from the M87 region as a whole is high is provided by observations of the diffuse X-ray flux from this part of the supercluster. Forman *et al.*[12] quote an emissivity of about $10^{43}\ \mathrm{erg\,s^{-1}}$ for this diffuse component, to be compared with our own estimate of $10^{38}\ \mathrm{erg\,s^{-1}}$ for the Galaxy, that is a ratio 10^5, a result only a factor 10 different from that required on our model for cosmic rays.

Finally some remarks can be made about the expected anisotropy. The magnitude of the anisotropy for particles diffusing from a source in the x direction is $\delta=(3D(E)/CN(x))\times dN(x)/dx$ and this has been evaluated for energies above 10^{18} eV where, on the present model, the particles are largely extragalactic. The values predicted are $\delta=1\%$, 4% and 20% for primary energies of 10^{18}, 10^{19} and 10^{20} eV, respectively. Measured anisotropies to date are imprecise, and firm evidence for finite anisotropies is absent above 10^{18} eV; however, there seems to be a trend in phases with increasing energy[13], not inconsistent with an approach to the Virgo direction above 10^{20} eV. The proof of the present model will clearly rest on the observation of such a collimation of arrival directions at these ultra-high energies.

An evolution free test for non-zero cosmological constant

Charles Alcock

The Institute for Advanced Study, Princeton, New Jersey 08450

Bohdan Paczyński*

Department of Astronomy, University of California at Berkeley, Berkeley, California 94720 and Princeton University Observatory, Princeton, New Jersey 08540

The cosmological constant has recently been questioned because of difficulties in fitting the standard $\Lambda = 0$ cosmological models to observational data[1,2]. We propose here a cosmological test that is a sensitive estimator of Λ. This test is unusual in that it involves no correction for evolutionary effects. We present here the idealised conception of the method, and hint at the statistical problem that its realisation entails.

Consider a collection of test objects emitting radiation containing spectral lines (so that redshifts may be determined), which are distributed on the surface of a sphere. (Any spherically symmetric, bounded distribution will do; this idealisation is for convenience only.) Let the sphere expand with the local Hubble flow. When observed at a great distance the redshifts of these objects will be confined to some narrow interval $(z - \Delta z, z + \Delta z)$, and their distribution on the sky will be confined in some circle of angular radius $\Delta\theta$. Our task is to evaluate $\Delta z/(z\Delta\theta)$.

We discuss only the homogeneous, isotropic cosmologies described by the Robertson–Walker metric[3],

$$ds^2 = -dt^2 + R^2(t)\left\{\frac{dr^2}{1-kr^2} + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)\right\} \tag{1}$$

where the dynamical evolution of the Universe is expressed by the equation

$$\dot{R}^2 = R^{-1}\left\{\frac{\Lambda R^3}{3} - kR + \frac{8\pi}{3}\rho_0 R_0^3\right\} \tag{2}$$

All symbols have their usual meanings. It is easy to evaluate $\Delta z/(z\Delta\theta)$ by tracing the null geodesics of this geometry. We do this and express the answer in terms of q_0 and Ω_0 by using[4],

$$\begin{aligned}\rho_0 &= \left(\frac{3}{8\pi}\right) H_0^2\,\Omega_0\\ \frac{k}{R_0^2} &= H_0^2\left(\frac{3}{2}\Omega_0 - q_0 - 1\right)\\ \Lambda &= 3H_0^2\left(\frac{1}{2}\Omega_0 - q_0\right)\end{aligned} \tag{3}$$

from which we obtain

$$\begin{aligned}\frac{\Delta z}{z\Delta\theta} = &\frac{\{\frac{1}{2}\Omega_0 - q_0 - (\frac{3}{2}\Omega_0 - q_0 - 1)(1+z)^2 + \Omega_0(1+z)^3\}^{1/2}}{z|\frac{3}{2}\Omega_0 - q_0 - 1|^{1/2}}\\ &\times \sum_k \left(|\tfrac{3}{2}\Omega_0 - q_0 - 1|^{1/2}\int_1^{1+z}\right.\\ &\left.\times\frac{dy}{\{\frac{1}{2}\Omega_0 - q_0 - (\frac{3}{2}\Omega_0 - q_0 - 1)y^2 + \Omega_0 y^3\}^{1/2}}\right)\end{aligned} \tag{4}$$

where

$$\sum_{+1}(x) = \sin x,\ \sum_{-1}(x) = \sinh x \tag{5}$$

In the case $k = 0$,

$$\frac{\Delta z}{z\Delta\theta} = z^{-1}\{1 - \Omega_0 + \Omega_0(1+z)^3\}^{1/2}\int_1^{1+z} dy\,\{1 - \Omega_0 + \Omega_0 y^3\}^{-1/2} \tag{6}$$

For the 'conventional' cosmologies where $\Lambda = 0$ there is the simple expression,

$$\frac{\Delta z}{z\Delta\theta} = \frac{(1+2q_0 z)^{1/2}}{q_0^2 z}\{q_0 z + (q_0 - 1)((1+2q_0 z)^{1/2} - 1)\} \tag{7}$$

Numerical evaluation of equation (7) shows that $\Delta z/(z\Delta\theta)$ is not a powerful estimator of q_0 in the $\Lambda = 0$ case—there is only 11% variation of $\Delta z/(z\Delta\theta)$ between $q_0 = 0$ and $q_0 = 1$ at $z = 2$. However, the general expressions (4) and (6) show great variations of $\Delta z/(z\Delta\theta)$ with the parameters. This is shown in Fig. 1.

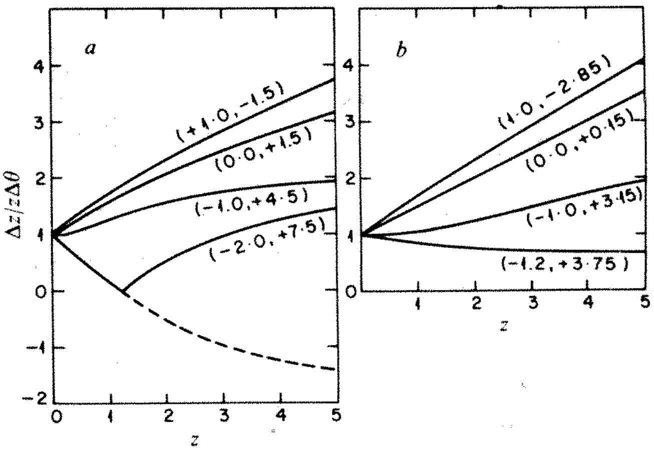

Fig. 1 The variation of $\Delta z/(z\Delta\theta)$ with z is plotted for cosmologies where *a*, $\Omega_0 = 1.0$; *b*, $\Omega_0 = 0.1$. Each curve is labelled by $(q_0, \Lambda H_0^{-2})$ where $\Lambda H_0^{-2} = 1.5\,\Omega_0 - 3\,q_0$. The drastic variations possible in $\Delta z/(z\Delta\theta)$ can be seen even at small z in the event that Λ is significant. The zeros of the lowest curve occur because of antipoles in the null geodesics. The dashed line gives the formal negative result of equation (4), describing apparent reflection of $\Delta\theta$ at the antipoles. The solid curve is the observable result. All of these models have initial singularities. (Note that with $\Omega_0 = 0.1$, $q_0 < -1.28$ means there was no initial singularity.)

The greatest advantage of this method is its independence of the evolutionary corrections which plague most other tests (the proposal to compare X-ray core radii with microwave diminution measurements is a promising exception[5,6]). There is the problem, however, that the natural 'test objects' are galaxies in clusters, which have large peculiar velocities. It will be necessary to separate statistically the peculiar and Hubble velocities in a large number of clusters of different angular extent, but at approximately the same mean redshift. This can be done (in principle) because the Hubble velocities scale $\alpha\ \Delta\theta$, whereas the peculiar velocities will have a very different dependence on $\Delta\theta$.

The analysis will require that there be some clustering which is not gravitationally relaxed. Candidate structures which have been observed at low redshifts might be superclusters[7], or long range correlations around rich clusters[8]. These structures show density enhancements over scales up to $\sim 20\,h^{-1}$ Mpc (where the Hubble constant h is in units of $100\ \mathrm{km\,s^{-1}\,Mpc^{-1}}$). The galaxy two-point correlation function could be measured in z and θ. If the observed correlations have the same shape in z and θ one may be confident that pollution of the Δz by peculiar motions is unimportant. (This is true because, in general, gravitational perturbations produce peculiar velocities with the scaling behaviour $\Delta z \propto \Delta\theta^{1/2}$. This will produce a very different

0028–0836/79/400358—02$01.00

shape in the correlation function than the linear relation being searched for.) By matching the amplitudes one constructs a measured $\Delta z/(z\ \Delta\theta)$ which can be used to estimate ΛH_0^{-2}.

It is reasonable to suppose that substantial clustering may occur without the accompanying peculiar velocities. Origins for clustered galaxies have been proposed where, because of dissipation, the peculiar velocities have been damped out. An example is the 'pancake' model[9] where galaxies form on caustics of the gas motion at redshift ≥10.

Helium gas-bubble superlattice in copper and nickel

P. B. Johnson* & D. J. Mazey

Metallurgy Division, UKAEA AERE Harwell, Oxon, UK

The microstructural changes occurring in metals during ion bombardment with helium or hydrogen isotopes have important implications in several areas of technology[1] such as in the deterioration of the accelerator targets suggested for use as intense neutron sources in cancer therapy[2]; and in the plasma-wall interactions which could strongly influence the operation of future thermonuclear fusion reactors (see ref. 3). Research has shown that helium ion irradiation of Mo[4,5], Cu, Ni and stainless steel[1] to high doses can result in a superlattice of small (~2 nm diameter) helium bubbles in very high concentration (~10^{25} m^{-3}) even at temperatures up to 0.35 T_m (refs 1, 4). The mechanisms involved in the bubble growth[6] and in the superlattice formation have been discussed but the role of displacement damage collisions on bubble growth has received little study. In the present work, specimens containing a superlattice of helium bubbles formed during prior helium ion irradiation have been irradiated with 1 MeV electrons to create a specific collision regime. This was found to induce bubble growth and changes in superlattice parameters, in both copper and nickel.

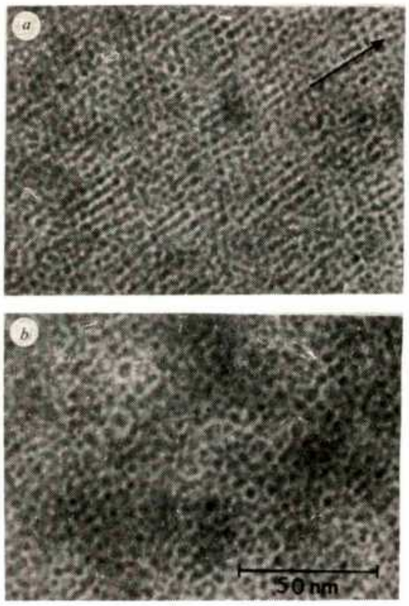

Fig. 1 *a* Direct transmission electron micrograph of helium gas bubbles in copper following helium-ion irradiation to a level of ~4×10^{17} 30 keV He ions cm^{-2} at 300 K. The 100 keV electron beam is along [110] in the matrix and is normal to the plane of the bubble-containing layer. The direction of the trace of one set of (111) matrix planes in the (110) plane is indicated. *b*, Direct transmission electron micrograph of the gas bubbles in the same specimen as *a* but in an area, of diameter ~2μm, which has been irradiated at 300 K with 1 MeV electrons to increase the damage dose by ~15 dpa without the deposition of further helium.

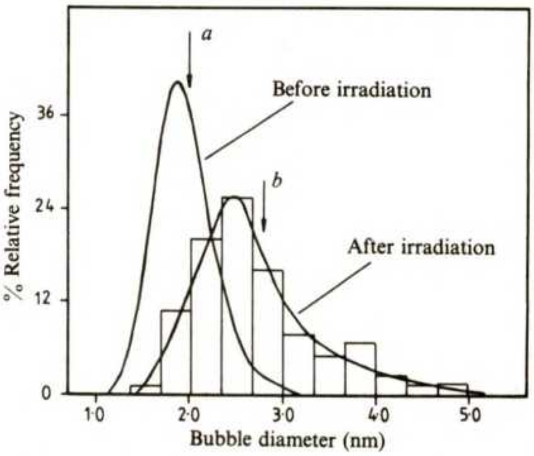

Fig. 2 Bubble size distributions corresponding to Fig. 1*a* and *b*. The average bubble diameters (based on average bubble volumes) indicated by the arrows are ~2.0 nm and ~2.8 nm respectively. It is evident that the 1 MeV electron irradiation has caused a coarsening of the bubble structure.

An annealed copper target was irradiated in bulk at 300 K with 30-keV helium ions at normal incidence and an electron-transparent specimen containing the bubble layer was prepared. The bubbles lay predominantly on a superlattice having an f.c.c. structure aligned with the copper matrix (see Figs 1*a*, 3*a* and ref. 1). The calculated value of the mean projected range was 97 nm with the maximum damage estimated to be ~23 dpa (displacements per atom) at depth ~80 nm. The subsequent 1 MeV electron irradiation at 300 K was carried out on the Harwell AEI HVEM. The damage dose over an irradiated area ~2 μm in diameter was calculated to be 15 dpa and was accumulated in 1 h at a rate similar to that occurring during the ion irradiation at the depth of maximum damage. High resolution microscopy was performed in a Philips EM301 100 keV electron microscope. Electron micrographs taken on, and outside, the 1 MeV electron irradiated area are shown in Fig. 1. For copper, bubble size distributions are shown in Fig. 2, and selected-area diffraction patterns in Fig. 3. It can be seen that following electron irradiation, there is an increase in the average bubble size. A similar result was obtained for nickel in the same conditions. At 300 K the thermal mobility of single vacancies is low in copper and negligible in nickel. The change in the electron diffraction pattern confirms that there has been a genuine change in the bubble structure.

The increase in the bubble lattice constant in copper (from ~7.0 nm to ~9.0 nm) suggests that bubbles may have moved apart under electron irradiation. Between the domains of good order evident in the bubble structure there are regions which seem less well developed[1]. It is possible that local lattice expansions are accommodated by a movement of bubbles outward from the domains into these regions.

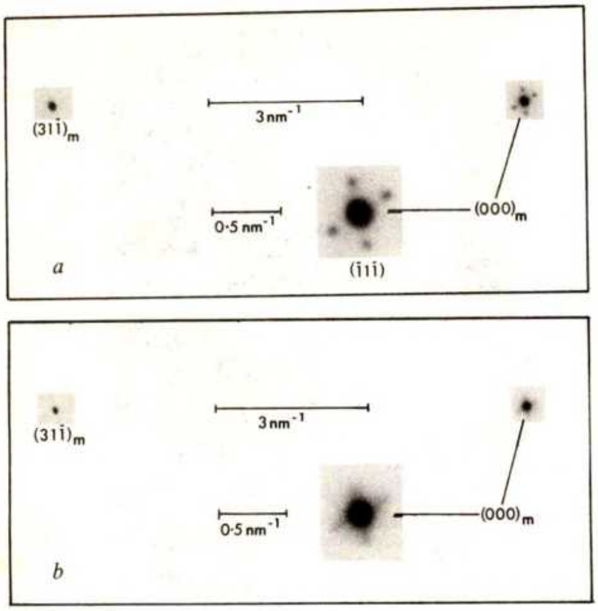

Fig. 3 A section of the [110] selected-area electron diffraction pattern from the copper specimen of Fig. 1. *a* and *b* are respectively outside and on the 1 MeV electron irradiated area. The electron energy is 100 keV. Diffraction from the bubble array causes the splitting that can be seen around the matrix reflections. The superlattice diffraction pattern centred on the (000) transmitted beam is shown enlarged as an inset in each case. Spots which were evident around the (000) reflection in the original negative of *b* have not survived reproduction here. Values for the average spacing between (111) bubble planes, as deduced from the separations of the (111) superlattice spots in the original negatives are ~4.0 nm for *a*, and ~5.2 nm for *b*. (Quantitative results were not obtained for nickel because the patterns were affected by the magnetic nature of the specimen.) The radial streaking evident in *b* shows that in this case there are interplanar spacings ranging from the quoted value through to higher values.

For irradiation at low temperature Evans[6] has suggested that the most likely growth mechanism is one in which overpressurised bubbles punch out interstitial dislocation loops. Assuming that this is the mechanism operating and that no significant long-range movement of the helium takes place during implantation, an estimate can be made of the helium content of the visible bubbles before the electron irradiation (P.B.J. and B. Newport, unpublished). For depths of ~100 nm only ~15% of the helium implanted seems to be in the bubbles. Although the uncertainties involved are large the general conclusion is that an appreciable fraction of the helium is trapped in the matrix probably in the form of helium-vacancy complexes[7]. The estimated density for helium in bubbles (~10^{23} atoms cm^{-3}) exceeds, by a factor ~3, the average value calculated for helium in the matrix at the same depth. This suggests that some helium atoms have moved to the bubbles from their initial place of implantation in the matrix during the course of the helium irradiation. There is no obvious increase in the bubble size once irradiation is stopped. The continued growth during electron irradiation may be in response to bubbles gaining further helium, and perhaps vacancies, displaced from the matrix as a result of electron–atom collisions. It should be emphasised, however, that there are other possibilities which cannot be ruled out.

That collision or displacement events alone can give rise to bubble growth is an important observation in relation to developing an adequate understanding not only of bubble growth during inert gas or proton irradiation but also of synergistic effects when different types of radiation are present, for example in a fusion reactor where the first-wall surface is expected to be bombarded by a variety of ions and particles of widely varying energy[3]. The results presented here could be explained by several different mechanisms acting either individually or in concert. Amongst these are: (1) processes involving the detrapping of helium from helium-vacancy complexes; (2) the radiation assisted migration of helium; (3) the dynamic re-solution of helium from existing bubbles and its redistribution; and (4) the athermal radiation stimulated migration of vacancies to the bubbles[8]. These and other mechanisms will need to be investigated in further experiments to elucidate their roles more precisely.

We thank colleagues at Harwell and Wellington for discussions. P.B.J. thanks the New Zealand Cancer Society and the Nuffield Foundation for financial assistance.

Identification of clear taenite in meteorites as ordered FeNi

Edward R. D. Scott

Department of Terrestrial Magnetism, Carnegie Institution of Washington, 5241 Broad Branch Road, N. W., Washington, DC 20015

Roy S. Clarke, Jr

Department of Mineral Sciences, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560

In the Fe–Ni system, the face-centred cubic (f.c.c.) phase (called taenite in meteorites) is stable for all compositions above 1,185 K. Below this temperature, the body-centred cubic phase (kamacite) is stable and has a maximum Ni concentration of about 7% around 720 K (ref. 1). Metal in meteorites is commonly found to contain kamacite with 4–7% Ni and taenite with 20–45% Ni. Taenite grains have M-shaped Ni profiles which formed on slow cooling during diffusion-controlled growth of kamacite and preserve a record of the cooling rates. Another Fe–Ni phase with 49–57% Ni was found in ordinary chondrites by Taylor and Heymann[2] and identified as a variety of taenite. They called it clear taenite to distinguish it from the zoned variety, which develops cloudy borders on etching with acid, and proposed that it nucleated at 660–610 K on the edge of isolated kamacite grains. We report here studies of meteoritic metal with reflected-light microscopy and electron-probe analysis, in which we discovered that clear taenite is optically anisotropic and we have found it in all meteorite groups. We use the term clear taenite as originally defined to include only alloys with ~48–57% Ni, not those with ~25–30% Ni, which Lin *et al.*[3] called clear taenite II. Except for cloudy taenite which contains ~30–40% Ni and looks cloudy because it is a submicroscopic two-phase mixture, taenite remains clear on etching. We conclude that clear taenite is the ordered, tetragonal FeNi phase found by Albertsen *et al.*[4–6] in two iron meteorites using Mössbauer and X-ray techniques, and that it formed from taenite, not kamacite. This tetragonal phase has been synthesised by irradiating FeNi alloys with neutrons or electrons below 593 K (refs 7, 8).

Optical anisotropy in clear taenite is best observed in well polished sections using oil-immersion objectives and a powerful

Table 1 Range and mean composition in wt % of 25 clear taenite grains in eight chondrites and mesosiderites determined by electron-probe analysis

	Range	Mean

source of polarised light. Contrast can often be improved by slightly uncrossing the polars. Clear taenite shows a characteristic pattern of irregular grains (Fig. 1) in which subdomains are usually visible. These subdomains show flame-like or more intricate arrangements and are probably magnetic domains judging from their similarity to those seen in cohenite (Fe_3C) in the same conditions. From the descriptions of Gooley *et al.*[9] it is evident that the mineral in which they found optical anisotropy was in fact Taylor and Heymann's clear taenite. Careful observations of a few large areas of clear taenite reveal three distinct orientations of grains, consistent with the symmetry change from cubic to tetragonal which occurs on ordering in FeNi. Because etching may cause apparent anisotropy, we used only unetched sections to characterise this mineral. In such sections, clear taenite is virtually identical in colour to the zoned taenite which is adjacent, although their interface may sometimes be observed without crossed polars.

In addition to the 10–60-μm diameter grains which Taylor and Heymann[2] identified, clear taenite occurs in sharply defined rims on normal zoned grains. These rims, which are 1–5 μm wide, contain 48–57% Ni and under crossed polars show an irregular grain structure which is characteristic of clear taenite. On etching it can be seen that the anisotropic taenite rim corresponds precisely to the zone of clear taenite between kamacite and cloudy taenite (Fig. 1). Electron probe traverses zoned taenite grains with broad rims in over 10 mesosiderites and chondrites (Figs 2 and 3) show a relatively homogeneous rim and a discontinuity at the interface between clear and cloudy taenite like that found in Estherville[10]. These features in the M-profile were not resolved by other workers (for example, refs 11, 12) because they did not analyse small favourably located grains with broad rims.

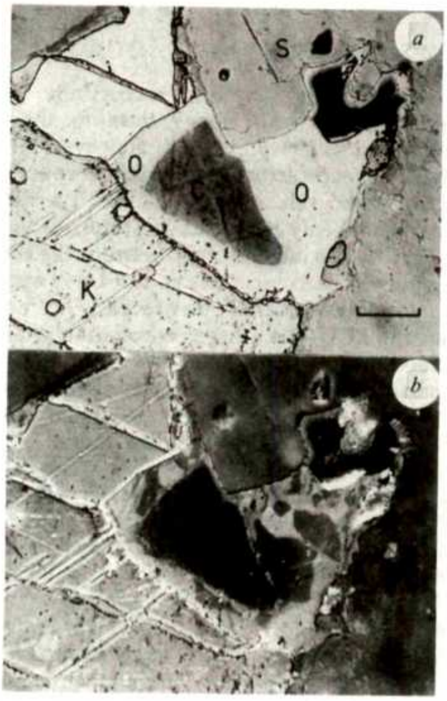

Fig. 1 Reflected light photomicrograph of metal grain in Mezö-Madaras, an L3 meteorite, etched with acid to reveal structure; *a*, polarised light; *b*, crossed polars. In *a* cloudy taenite (C) is surrounded by a white rim of clear taenite (O). Crossed polars show that clear taenite is optically anisotropic and reveal an irregular grain structure. Clear taenite is surrounded by kamacite (K) and silicate (S). (Polished section is carbon coated; this enhances contrast between grains in clear taenite by reducing the visibility of the subdomains.) Scale bar, 20 μm.

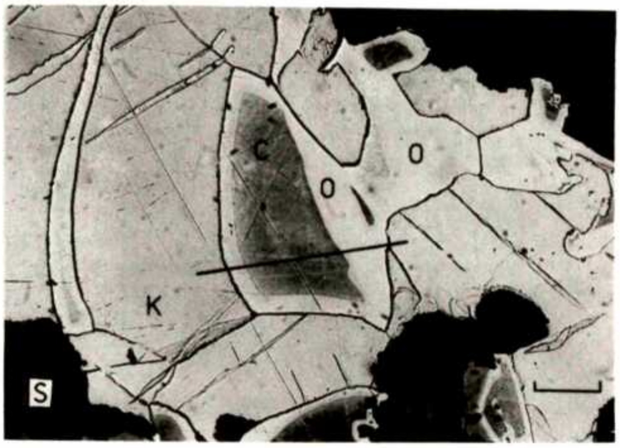

Fig. 2 Reflected light micrograph of metal grain in Mezö-Madaras. The line across the cloudy taenite grain (C) which is rimmed by ordered clear taenite (O) marks the location of the compositional profile shown in Fig. 3. Kamacite, K; silicate, S; scale bar, 20 μm.

We have found optical anisotropy in clear taenite from over 40 meteorites including H, L, LL and CO3 chondrites, diogenites, iron meteorites, mesosiderites and pallasites and conclude that all slowly cooled meteorites with zoned taenite contain some clear, anisotropic taenite also. Table 1 summarises the compositions of clear taenite found by electron-probe analysis of eight meteorites. With the exception of reheated meteorites and heat-affected surfaces we have not found normal isotropic taenite with compositions in the range 46–60% Ni.

The intimate association of clear taenite with zoned taenite and its growth on grain boundaries within polycrystalline taenite show that few clear taenite grains could have formed in isolated kamacite grains as Taylor and Heymann[2] suggested. Instead we propose that large clear taenite, which is found in ordinary chondrites and mesosiderites, formed by the inward growth of clear taenite rims at low temperatures (<700 K). In the mesosiderites Estherville and Emery and the L chondrite Mezö-Madaras, we have seen complete sequences of structures ranging from large clear taenite grains enclosing micrometre-sized blobs of cloudy taenite to large-zoned grains with micrometre-wide rims of clear taenite enclosing cloudy taenite. In most chondrites the intermediate stages in this sequence are less common and there seem to be two distinct populations of grains. Diffusion of Ni through up to 30 μm of clear taenite, which is required in our mechanism, may be facilitated by the numerous grain boundaries.

Even in pallasites and slowly cooled iron meteorites, massive clear taenite grains are absent and the clear rims on zoned grains are relatively narrow compared with those in chondrites. This may be a result of relatively high metallic concentrations of P, which reduce the equilibrium concentration of Ni in taenite[13]. Taenite with about 50% Ni has also been reported in shocked sulphides in irons[14]. Other processes must be responsible for its formation there.

The anisotropic FeNi mineral which we have described is undoubtedly the ordered phase reported by Albertsen *et al.*[5,6] in two iron meteorites. They identified it by the similarity of its Mössbauer spectrum to that of tetragonal FeNi synthesised with neutron irradiation[7,8] and the presence of X-ray reflections

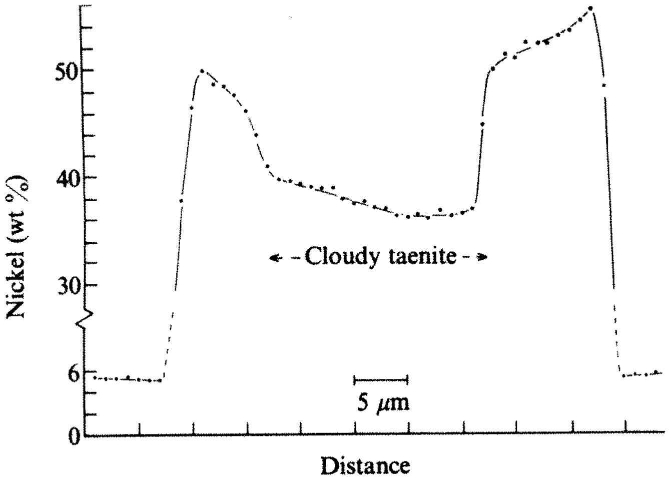

Fig. 3 Electron probe Ni profile across composite taenite grain shown in Fig. 2. The Ni profile is not smooth as others have found; instead there are discontinuities between the clear taenite rim which has 46–55% Ni and the cloudy taenite which has less than 40% Ni.

which violated the f.c.c. lattice of taenite. The only possible ordering arrangement which satisfied their data was the tetragonal L10 structure (AuCu), which can be derived from taenite by ordering Fe and Ni atoms on alternate (002) planes. From etching experiments on zoned taenite lamellae, Albertsen *et al.*[6] deduced that FeNi was concentrated in the outer rims of these lamellae. Our observations and probe analyses of anisotropic rims are entirely consistent with their work, and taken together they characterise clear taenite containing 48–57% Ni as a new mineral.

Ordered FeNi areas several micrometres in size have also been reported[15,16] in another iron meteorite, Santa Catharina, which contains 34% Ni (ref. 14). Nickel could not have been concentrated in this iron by growth of kamacite, which is virtually absent; instead, local oxidation of Fe has been suggested as a mechanism by Bowles *et al.*[15] but refuted by Danon *et al.*[16]. Although the meteorites in which we observed clear taenite are not all entirely unoxidised, the areas which we studied were free from visible oxidation.

As the phases in cloudy taenite can only be resolved by electron microscopy[3,10] we cannot confirm that cloudy taenite also contains ordered FeNi (refs 4, 5). It is plausible that exsolution in the cloudy zone is triggered by ordering of FeNi, possibly through spinodal decomposition. Electron microscopy of Santa Catharina by Jago[17] did show two submicrometre taenite phases in a structure which seemed to be a precursor to cloudy taenite. However he detected extra reflections consistent with ordering in taenite (and kamacite) only after the second taenite had disappeared on heating at 200 °C.

Estimates of cooling rates[11,12] ignore the existence of ordered FeNi rims and the two-phase nature of cloudy taenite. Although this is unlikely to cause large errors, a quantitative investigation of these effects is needed. The abundances of clear and cloudy taenites provide a useful visual estimate of the cooling rate as there are rough inverse correlations between abundances and cooling rates.

We thank R. S. Rajan for discussions, and C. G. Hadidiacos and E. Jarosewich for the provision of electron probe facilities at the Geophysical Laboratory and the Smithsonian Institution, respectively.

On the total CO_2–titration alkalinity–oxygen system in the Pacific Ocean

Chen-Tung A. Chen & Ricardo M. Pytkowicz

School of Oceanography, Oregon State University, Corvallis, Oregon 97331

Decomposition of organic matter changes the concentrations of carbon, nitrogen, phosphorus, oxygen and titration alkalinity (TA) in the ratio 106:16:1:138:–17 (refs 1–3), so the combined effect of decomposing *x* mol of $CaCO_3$ and *y* mol of organic matter in 1 kg of seawater on the preformed total CO_2 (ΣCO_2^0), preformed TA (TA^0), biogenerated ΣCO_2 [$\Delta\Sigma CO_2$(biol)] and the apparent oxygen utilisation (AOU) can be represented as[4]

$$\Delta\Sigma CO_2 = \Sigma CO_2(\text{measured}) - \Sigma CO_2^0 = x + 106y$$

$$\Delta TA = TA(\text{measured}) - TA^0 = 2x - 17y$$

$$\Delta\Sigma CO_2(\text{biol}) = 106y; \qquad AOU = 138y$$

Eliminating *x* and *y* from the above equations yields

$$\Delta\Sigma CO_2(\text{biol}) = 0.768\ AOU \tag{1}$$

$$\Delta\Sigma CO_2 - 0.5\Delta TA = 0.83\ AOU \tag{2}$$

Several early workers[5–8] have successfully correlated $\Delta\Sigma CO_2$(biol) to AOU with slopes close to the Redfield, Ketchum and Richards (RKR) model[1]. However, the methods used often have not satisfactorily taken into account the variation of the preformed values for ΣCO_2 and TA with sample depth or have mistakenly taken $\Delta\Sigma CO_2$(biol) to be equal to $\Delta\Sigma CO_2 - 0.5\Delta TA$. The inconsistency between the correlations above and below the thermocline is also not well explained. A modified computational scheme[5,8] has recently been developed for calculating the ΣCO_2-TA-oxygen correlation with the depth dependent variations of ΣCO_2^0 and TA^0 accounted for. The method of calculating $\Delta\Sigma CO_2$ is the same as that described in ref. 4 but further useful information has been obtained by plotting $\Delta\Sigma CO_2$ against AOU, rather than depth. The results in the Pacific Ocean, presented here, suggest a linear correlation between the bio-generated CO_2 and AOU with a slope of 0.722 ± 0.05, in good agreement with that predicted from the RKR model. The deviation of the data from this linear correlation for shallow water can largely be explained by the influences of human induced CO_2.

The values for ΣCO_2^0 and TA^0 are needed in order to calculate $\Delta\Sigma CO_2$ and ΔTA. It has been shown[8,9] that the surface values of ΣCO_2 and TA show a linear correlation with temperature. Using more recent data (Geochemical Ocean Section Study, Atlantic Ocean), Chen and Millero[4] have confirmed that TA^0 and ΣCO_2^0 show a linear temperature dependence on the constant salinity basis, but only at the lower temperatures. We have, therefore, normalised the values for ΣCO_2^0 and TA^0 in the Pacific Ocean (GEOSECS) to 35‰ salinity using

$$\Sigma CO_2^0(\text{or } TA^0) = \frac{\Sigma CO_2^0(\text{measured}) \ [\text{or } TA^0(\text{measured})] \times 35.000}{S(‰, \text{measured})}$$

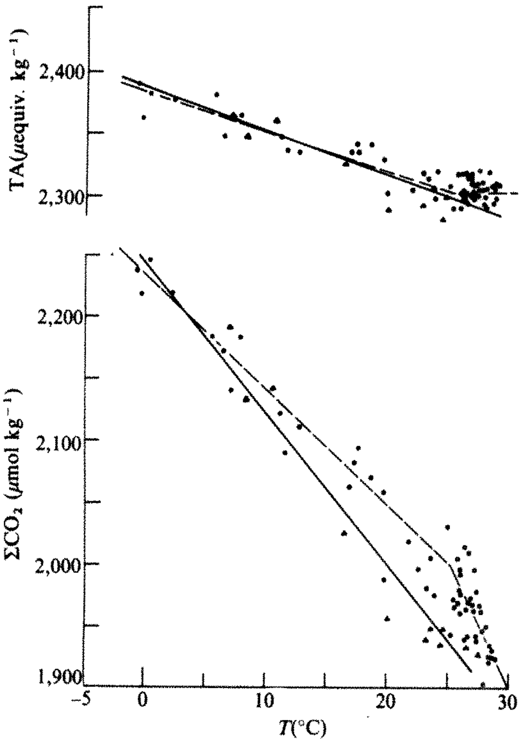

Fig. 1 The surface TA and ΣCO_2 values, normalised to 35‰ salinity, at various temperatures. The triangles and the solid line represent the data in the Northwest Pacific. The circles and the dashed line represent the data elsewhere in the Pacific Ocean.

These normalised values also correlate with the potential temperature in the Pacific Ocean although they seem to fall in two groups (Fig. 1). Stations in the north-west region (shaded area on Fig. 2) seem to have different values for ΣCO_2^0 and TA^0 than the rest of the Pacific Ocean. As a result, the following equations are used to represent ΣCO_2^0 and TA^0 in the north-west region (triangles, represented by solid lines on Fig. 1):

$$\begin{aligned} \Sigma CO_2^0(\mu\text{mol kg}^{-1}) &= 2{,}242 - 12.08\theta\ (\pm 18) \\ TA^0(\mu\text{equiv kg}^{-1}) &= 2{,}384 - 3.36\theta\ (\pm 11) \end{aligned} \qquad (3)$$

Whereas, the following equations are used to represent the values elsewhere in the Pacific (circles, represented by dashed lines on Fig. 1):

$$\begin{aligned} \Sigma CO_2^0(\mu\text{mol kg}^{-1}) &= 2{,}236 - 9.4\theta\ (\pm 21) \qquad \theta \leq 25\,°\text{C} \\ &= 2{,}500 - 20\theta\ (\pm 23) \qquad \theta > 25\,°\text{C} \end{aligned} \qquad (4)$$

$$\begin{aligned} TA^0(\mu\text{equiv kg}^{-1}) &= 2{,}383 - 3.1\theta\ (\pm 10) \qquad \theta \leq 25\,°\text{C} \\ &= 2{,}306 \qquad\quad (\pm 10) \qquad \theta > 25\,°\text{C} \end{aligned} \qquad (5)$$

The numbers in parentheses give one standard deviation of the least squares fit for the above equations. The salinity and higher order temperatures terms are not statistically significant.

The GEOSECS station GS 347 has been chosen as a demonstration station. The values for $\Delta\Sigma CO_2 - 0.5\Delta TA$ calculated from equations (2)–(5) are plotted against AOU in Fig. 3. The dashed line (*a*) on Fig. 3 has a slope of 0.83, therefore, one might expect the data points to fall on the line if both the computational scheme and the RKR model are correct. This is clearly not the case. Although the sample at 20 m falls near the theoretical line, that at 189 m falls away from it and that at 336 m falls even further away. The samples below 589 m deviate from line *a* the most but seem to correlate linearly with AOU (line *b*) with a slope of 0.76 ± 0.05 similar to that predicted by the RKR model.

Two possibilities may explain the phenomenon, which is typical for the stations we examined. First, that the RKR model is invalid in the near-surface layer but becomes valid for deep waters—this seems unreasonable. Second, there may be a deficiency in our computational scheme—the values of present-day ΣCO_2^0 used to calculate $\Delta\Sigma CO_2$ might not represent the values of ΣCO_2^0 for waters formed in the past.

Human activities, mainly the burning of fossil fuels and possibly also the cultivation of virgin lands and clearing of forests, have significantly increased the amount of CO_2 in the atmosphere over the last 130 years[10–18]. Recent work[4,19–21] has shown that the human-induced CO_2 has penetrated into the oceans. Consequently, the ΣCO_2^0 values calculated from the present-day data probably are higher than the ΣCO_2^0 values for old waters. The values for TA^0 probably do not vary with atmospheric CO_2 and we will assume that the present-day TA^0 values represent the values of TA^0 for water of various ages in our discussion.

Since the values of ΣCO_2^0 for younger waters are closer to the present-day ΣCO_2^0 values (equations (3) and (4)), the computational scheme is 'more correct' for younger waters. This agrees with the data shown on Fig. 3; the shallower, and presumably, younger samples fall closer to the theoretical line. The waters below 589 m deviate from the line by a nearly constant amount which indicates that the ΣCO_2^0 values for these waters deviate from the present day ΣCO_2^0 by approximately a constant amount. In other words, the waters below 589 m probably have not felt the influence of the atmospheric CO_2 variations. Although the ^{14}C and tritium have different source function and equilibration time as compared to CO_2, their vertical distributions[22] seem to substantiate this conclusion, at least qualitatively (Fig. 3). Very little tritium, but large negative values for $\Delta^{14}C$ have been found below 590 m.

It is generally accepted that protein is utilised more readily than carbohydrate as particulate organic matter is transported from surface to deep waters[23–26], consequently, the C/N/P/O ratio changes accordingly. However, our results indicate that since the changes in the masses of nitrogen and phosphorus are small as compared to the changes in the masses of carbon and oxygen, the changes in the C/N, C/P, N/P, N/O and P/O ratios probably do not significantly affect the C/O ratio. The preferential retention of carbon over oxygen in upper waters could indeed change the C/O ratio. However, this process has to be significantly effective everywhere from surface to 589 m deep. No known process and no experimental data support this. As a result, the increase of ΣCO_2 due to the bioregeneration correlates linearly with AOU (line *b* on Fig. 3) below 589 m with a slope close to the value predicted by the RKR model.

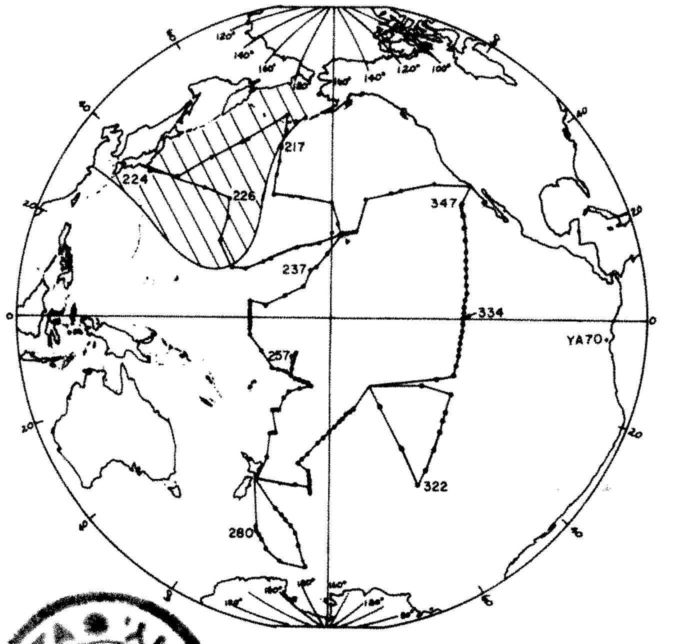

Fig. 2 Station locations in the Pacific Ocean.

The deviation of the data from the predicted values in the upper layer probably is largely caused by the influx of human induced CO_2. The best linear fit of the values for $\Delta\Sigma CO_2 - 0.5\Delta TA$ gives a value of $41 \pm 15\ \mu mol\ kg^{-1}$ (the distance between O and A) at AOU = 0. The value of $41 \pm 15\ \mu mol\ kg^{-1}$ probably represents the change in ΣCO_2^0 ($\Delta\Sigma CO_2^0$) due to the change of CO_2 concentration in the atmosphere. (The uncertainty of $\pm 15\ \mu mol\ kg^{-1}$ reflects only the random error due to scatter of the observed data and does not include any systematic error.) Integrating $\Delta\Sigma CO_2^0$ from surface to 589 m gives a total CO_2 increase of $1.2\ m\,mol\ cm^{-2}$. As a very crude first approximation, we assumed that the average difference in the concentration of man-made ΣCO_2 was $5 \pm 5\ \mu mol\ kg^{-1}$ between surface and 589 m over the last 130 yr and arrived at an eddy diffusion coefficient of $3.5 \pm 3.5\ cm^2\ s^{-1}$. The value is in reasonable agreement with the findings of Pytkowicz for oxygen[27] and Oeschger *et al.* for CO_2[28].

Data from stations widely scattered in the Pacific Ocean (Fig. 2; GS 217, 224, 226, 237, 257, 280, 322, 334, 347 and YALOC 69 station 70) have also been examined and the results follow the same pattern as GS 347. The values for $\Delta\Sigma CO_2 - 0.5\Delta TA$ for these stations have been plotted against AOU in Fig. 4. These values from the deep layers (filled circles; depth varies from below 100 m at YA 70 to below 1200 m at GS 226 and 322) correlate linearly (line *b*) with AOU with an average slope of 0.78 ± 0.05, which corresponds to a slope of 0.722 between $\Delta\Sigma CO_2$ (biol) and AOU. The data from the shallower layers (open circles) deviate from this best fit straight line with the near surface values centred around (0, 0) interception. Line *a* has the same slope as line *b* but is drawn through the (0, 0) interception. The vertical distance between a data point and line *a* probably represents the difference between the previous and present ocean surface ΣCO_2 concentrations.

Note that our computational scheme represents only first approximations of the very complicated system in the oceans[4]. Although the decrease of TA^0 and ΣCO_2^0 with increasing temperatures can be qualitatively explained as due to the decrease in the solubility for $CaCO_3$ and CO_2, the magnitude of the decrease cannot yet be estimated theoretically. There is also no satisfactory explanation as to why the correlations of TA^0 and ΣCO_2^0 with temperature change slope at higher temperatures. Whether they are caused by the change in the biological activity, or by the change in current flow patterns, or other physical processes such as equatorial upwelling[29] deserves further investigation. Moreover, the GEOSECS summer data in the Pacific Ocean have been used in our calculations although the winter TA^0 and ΣCO_2^0 concentrations in the Atlantic and Pacific polar regions where intensive vertical mixing occurs may be different from the Pacific summer data. This summer–winter incompatibility may cause a systematic error in addition to the random error. However, our preliminary estimation indicates that the $\Delta\Sigma CO_2^0$ value calculated here is unlikely to be systematically too high by more than $15\ \mu mol\ kg^{-1}$. A maximum value of $26\ \mu mol\ kg^{-1}$ in $\Delta\Sigma CO_2^0$ would give an eddy diffusion coefficient of $2.2 \pm 2.2\ cm^2\ s^{-1}$, which is in good agreement with the results of Pytkowicz[27] and Oeschger *et al.*[28]. The slope of the $\Delta\Sigma CO_2 - 0.5\ \Delta TA$ against AOU correlation would remain essentially the same, however.

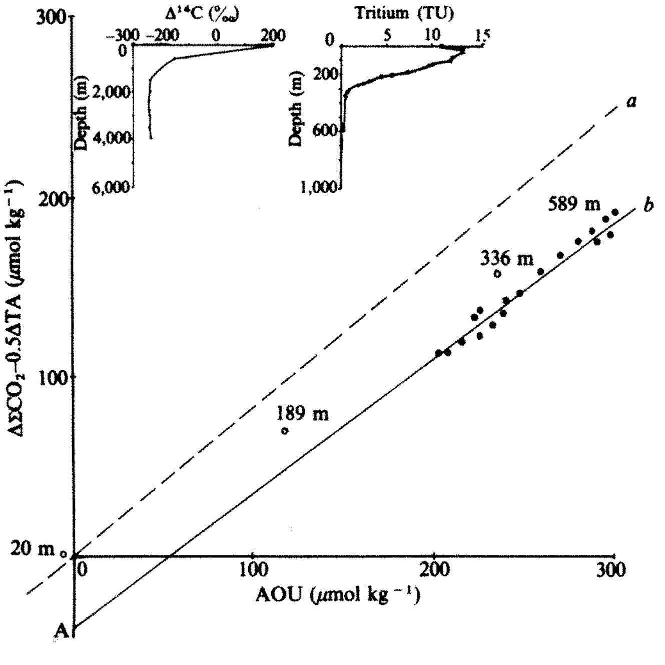

Fig. 3 The relationship between $\Delta\Sigma CO_2 - 0.5\Delta TA$ and AOU at GS 347. Open circles denote young waters and filled circles, old waters. Line *a* represents the theoretical correlation predicted from the RKR model. Line *b* is the best-fit correlation for the old water samples. The insert shows the tritium (in tritium units, TU) and $\Delta^{14}C$ (‰) profiles.

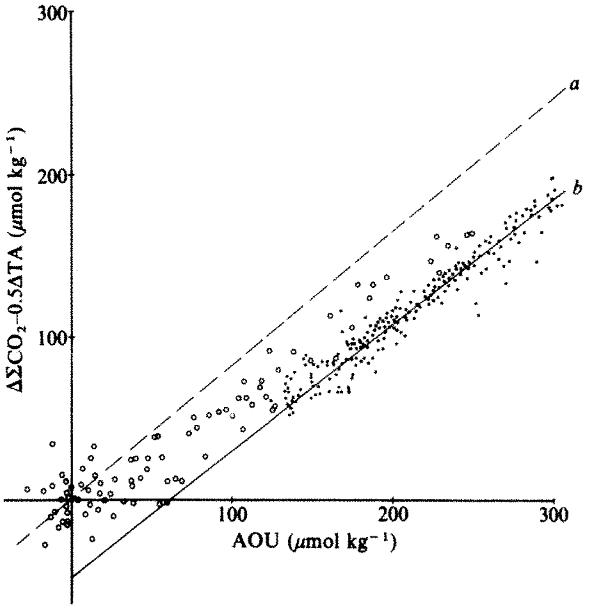

Fig. 4 The relationship between $\Delta\Sigma CO_2 - 0.5\Delta TA$ and AOU at 10 stations in the Pacific Ocean. Line *b* is the best fit straight line for the old water samples (filled circles). Line *a* has the same slope as line *b* but is drawn through the (0, 0) interception.

These data were obtained as part of the Pacific GEOSECS Expedition carried out aboard RV Melville of the Scripps Institution of Oceanography during 1973 and 1974. The shipboard work was largely carried out by personnel of the GEOSECS Operations Group under the direction of the late Arnold E. Bainbridge.

Access to this data and stimulating discussions with J. M. Gieskes and C. D. Keeling are acknowledged. We thank H. G. Ostlund for supplying the tritium and ^{14}C data before publication and L. F. Small for helpful comments. The work was supported by the School of Oceanography, Oregon State University and by grants from the Oceanography Branch of the NSF (OCE-78 20449, OCE-77 00018) and the Office of Naval Research (contract N00014-79-C-0004 under project NR 083-102).

Primitive lead in deep crustal xenoliths from the Snake River Plain, Idaho

William P. Leeman

Department of Geology, Rice University, Houston, Texas 77001

The petrology and geochemistry of deep crustal rocks are poorly understood due to the inaccessibility of such materials. Most inferences of the lower crust are based on studies of ancient high-grade metamorphic terranes now exposed after a history of deep burial. However, direct sampling of deep crustal rocks is feasible when they are carried to the surface as accidental fragments (or xenoliths) in lava flows. Ferro-basalt to ferro-latite lavas from Craters of the Moon lava field (COM) in the Snake River Plain, southern Idaho are characterised by variable and high $^{87}Sr/^{86}Sr$ ratios (0.708–0.712) interpreted as reflecting variable degrees of crustal contamination[1,2]. Some of these lavas contain xenoliths of crustal derivation (silicic charnockites and pyroxene granulites) that are found nowhere in the vicinity in surface outcrops. I present here initial isotopic and trace element results for a suite of these crustal xenoliths. As part of a detailed Pb isotopic study of the lavas (in preparation), three granulites were analysed to test the contamination hypothesis. The results indicate an affinity between the xenoliths and many exposed granulite-facies metamorphic terranes, and the unusually primitive lead isotopic ratios recorded establish the presence of early Archean crust beneath south-central Idaho.

The crustal xenoliths all contain quartz, plagioclase, Fe–Ti oxides, and hypersthene ± clinopyroxene ± alkali feldspar. These mineral assemblages place the rocks in the granulite facies at intermediate crustal depths. Three fresh xenoliths, 15–50 cm in approximate diameter, were sampled by drilling 1.2-cm cores, weighing about 30–50 g, from central portions of the rocks. In one case a core was taken near the xenolith rim to test for contamination from the host lava. The cores were washed in dilute HCl and deionised triple-distilled H_2O, crushed in a WC mill, digested in HF–$HC10_4$ in Teflon beakers in a low-Pb laboratory. Pb was separated by a $Ba(NO_3)_2$ precipitation and purified by anodic electrodeposition. Pb isotopic compositions and trace element concentrations were determined on separate dissolutions. Analyses were made on a 30 cm NBS-design mass spectrometer using the Si-gel method and isotopic compositions were corrected for mass fractionation by the double-spiking method[3]. Blanks run with these samples averaged about 5 ng and are insignificant for the reported analyses. All isotopic ratios are accurate to about 0.15% relative to NBS standard SRM-981. Pb, U, Th, Rb and Sr concentrations were determined by isotope dilution methods and are accurate to within 3% of the amount present. Table 1 shows replicate analyses (full procedural duplicates).

Isotopic compositions of the xenoliths are extremely primitive and are quite distinct from the host and all other analysed COM lavas. Core and rim analyses of xenolith CKI-1 are marginally distinct, but in fact the rim sample is the least radiogenic and seemingly precludes addition of Pb to the xenolith from the host lava. Isotopic ratios for this xenolith are among the least radiogenic values reported from the US. The $^{206}Pb/^{204}Pb$ and $^{207}Pb/^{204}Pb$ ratios plot near the 2,900 Myr isochron through the Stacey–Kramers growth curve for conformable ore leads[4] and

indicate that CKI-1 represents a terrane at least that old. Other reasonable growth curves (for example, a single-stage growth curve with a ^{238}U/^{204}Pb value of about 8.5 and Th/U value of about 6) yield model lead isotopic ratios similar to those in CKI-1 at about 2,900 Myr ago. The actual age of the xenolith (or strictly speaking, the age of granulite metamorphism) is probably slightly greater than 2,900 Myr because no correction has been applied to the observed isotopic ratios to account for *in situ* decay of U and Th isotopes. This correction is not large for CKI-1 due to its low U and Th contents. Acid leaching studies are in progress to estimate more closely the initial lead isotopic composition of this rock. The other xenoliths are somewhat more radiogenic than CKI-1 in accordance with their higher U and Th contents. The model age for CKI-1 is supported by a ^{207}Pb/^{204}Pb–^{206}Pb/^{204}Pb secondary isochron age of 2,870 Myr for the pair of xenoliths, CKI-1 and 70–40. However, a secondary isochron age of 3,760 Myr is indicated for the pair, SI-1 and CKI-1; this result probably reflects complex pre-metamorphic evolution of the lead in these two rocks. Further work is required to define the pre-metamorphic history of the COM xenoliths.

All of the xenoliths have high K/Rb ratios (730 to 1,360) and very low U contents and two have low Th contents. These geochemical features are characteristic of high-grade metamorphic terranes[5]. Considering their primitive lead isotopic compositions, it is clear that the low U and Th contents reflect depletions of these elements during an ancient metamorphic event and cannot have resulted from interaction with the host lavas. Thus it is clear that these few samples record the presence of a deep Archean basement complex at least several hundred kilometres west of other known outcrops in the northern Rocky Mountains. Archean metasedimentary rocks (2,500 Myr) occur south of the Snake River Plain in the Albion Range[6], but these are of a lower metamorphic grade than the COM xenoliths.

Sr isotropic ratios for the COM xenoliths are high and, with the low Rb/Sr ratios, provide a further indication of the antiquity of the underlying crust. The few available Rb-Sr data[1] are too scattered to provide a whole-rock isochron. If the model lead age is accepted, it is likely that the xenoliths were characterised by varied initial ^{87}Sr/^{86}Sr ratios unless the Rb-Sr systematics have been disturbed.

This work was carried out at University of Texas at Dallas. I thank W. I. Manton for hospitality and assistance. Field work was supported by grants from the National Geographic Society and the Penrose Fund of the Geological Society of America.

Biopedological origin of peatlands in South East Alaska

F. C. Ugolini & D. H. Mann

College of Forest Resources, University of Washington, Seattle, Washington 98195

Peatlands are the final stage in plant succession on level surfaces in South East Alaska, a region where bogs and forests in the process of turning into bogs occupy nearly as much surface area as do forests proper[1–3]. Plant succession in this area is in part conditioned by progressive bogging[4]; however, no previous attempts have been made to relate paludification to soil development. We now propose that the formation of peatlands in the Lituya Bay area of South East Alaska is caused by the deterioration of the internal drainage of the soil as an iron-cemented pan develops during the process of podzolisation. This situation provides a clear example of soil-induced bog formation, a process that may be important in other parts of the world.

Along the coast of the Gulf of Alaska, in Glacier Bay National Monument, tectonic uplift along the active Fairweather Fault and eustatic sea-level changes have produced marine terraces (Fig. 1). The wave-planed, seaward-sloping bedrock of the terraces is covered by 2–4 m of beach sands and gravels. The terraces provide a chronosequence of surfaces on which plant communities and soils have developed.

Terrace A, the lowest, is 150 m wide with an average elevation of 9 m above sea level; its minimum age is estimated at 400 yr from the ages of the oldest trees (Fig. 2). Terrace B is approximately 250 m wide with an average elevation of 26 m; its estimated age is $2\text{–}3 \times 10^3$ yr (ref. 5). Terrace C is 1,600 m wide with an average elevation of 80 m, and is estimated to be $6\text{-}8 \times 10^3$ yr old[5].

We investigated five transects across these terraces near Lituya Bay. For each transect, soils and the vegetation were described, and the ages of the largest trees determined by coring. We will describe here the results from a representative transect, the Steelhead Transect, 10 km south-east of Lituya Bay (Figs 1, 2).

The seaward edge of terrace A is covered by rye grass (*Elymus arenarius*) and supports immature soils with A/C sequences (regosols or typic udipsamments). A Sitka spruce (*Picea sitchensis*) forest occupies the inland side of this terrace, and the soil has weakly developed B horizons with A(B)C profiles.

The seaward side of terrace B is covered by Sitka spruce with western hemlock (*Tsuga heterophylla*) in the understory. Soils on the seaward side are mature typic haplorthods or placorthods (podzols) with an A2, a friable B2hir and a firm or cemented B2ir horizon. The inland side of terrace B is dominated by western hemlock and Alaska yellow cedar (*Chamaecyparis nootkatensis*). The soils exhibit thick organic horizons, impervious B horizons (placic horizons) and impeded drainage.

Alaska yellow cedar and mountain hemlock (*Tsuga mertensiana*) form a stunted forest on the seaward edge of terrace C. Soils in this forest are histosols (peat soils) with some spodic (podzolic) characteristics, but the organic horizons are in excess of 1 m and extremely poorly drained. The rest of terrace C is occupied by peatland vegetation dominated by sphagnum, sedges and ericaceous shrubs growing on 1.5–2.0 m of well decomposed peat. This peat lies on a thin (15 cm), compacted, iron-stained layer, rich in woody organics, resting on sand which shows no morphological or chemical evidence of B2hir or B2ir horizons. Biotic remains in this profile indicate a successional change from forest to peatland. The basal woody layer contains remains of a carabid beetle, *Patrobus fossifrons*, which normally does not inhabit sphagnum bogs[6]; abruptly above this level seeds of the bog plant *Menyathes trifoliata* appear.

The successional sequence is further described by the following chemical, physical and biological parameters of the soil. With distance from the sea, the organic horizon thickness increases from 2 to 20 cm across terrace A and from 22 to 35 cm across terrace B. On terrace C, a 100-fold increase occurs across the stunted forest/peatland boundary. The abundance of collembola and mites in organic horizons provides an index of the decomposition due to aerobic organisms. These soil arthro-

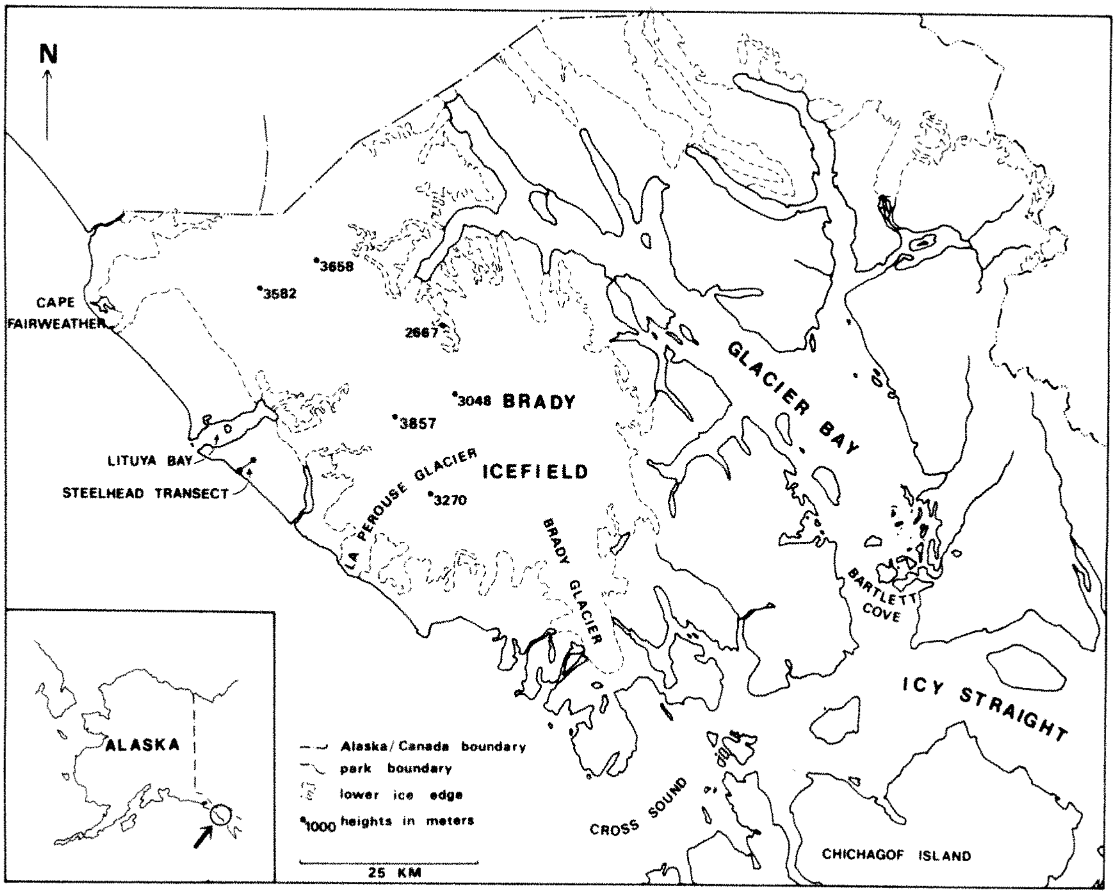

Fig. 1 Map of Glacier Bay National Monument, Alaska, showing the Lituya Bay and the location of study site.

pods disappear rapidly inland along the transect, reaching lowest numbers in the stunted forest of terrace C. The *p*H decreases with increasing age and development of the soil. It decreases 2.5 units between the beach meadow and the bog, the greatest drop occurring at the start of the conifer forest. The amount of iron in the B horizon, as crystalline, inorganic amorphous, and organically complexed, parallels the soil development; it increases from 0.16% in the beach meadow to a maximum of 1.84% in the B2hir of the seaward side of terrace B. It decreases rapidly on terrace C as the soils become more poorly drained. The organically complexed iron increases from 0.60% in the B2 horizon at the rear of terrace A to a maximum of 1.00% in the B2ir of the seaward side of terrace B. Such iron is progressively depleted at the rear of terrace B and on terrace C. Virtually the only form of iron left in the profile at the bog site is organically complexed and associated with the basal layers of woody peat. The log of saturated flow of intact soil cores decreases from 1 ml min^{-1} cm^{-2} in the B2 of terrace A to −3.5 ml min^{-1} cm^{-2} in the B2hir of terrace C. Field observations revealed an abundant flow of water along the surface of the B2hir in several profiles on terraces B and C.

The above observations clearly show that the terraces near Lituya Bay comprise a soil and vegetation chronosequence spanning about 8,000 yr and telescoped into an horizontal distance of less than 1 km. The rapid rates of both soil formation and plant succession are favoured by the maritime climate of South East Alaska which allows an unusually long growing season for this latitude[7]. Heavy precipitation (280 cm) and low evapo-transpiration encourage lush plant growth and rapid mineral weathering.

The terrace chronosequence near Lituya Bay offers a new perspective on the interaction between soil development, paludification and plant succession in South East Alaska. We propose the following sequence of events for peatland development on the terraces south-east of Lituya Bay (Fig. 3). (1) Soil-forming processes initiate the development of genetic horizons on surfaces newly emerged from the sea. (2) The accumulation of sesquioxides in the B horizon, induced by podzolisation, results in the formation of placic horizons. In South East Alaska placic horizons are known to appear after about 500 yr[8]. (3) Placic horizons cause deterioration of the soil's internal drainage, creating anaerobic conditions in the overlying horizons with attendant lowering of the decomposition rate of organic matter in the forest floor. Field observations show that placic horizons form an effective barrier to plant roots. (4) Because of slowed decomposition, litter accumulation on the forest floor proceeds rapidly. (5) At some point, equivalent to the stunted forest zone of terrace C, the litter layer surpasses a critical mass and becomes capable of retaining water the whole year round to maintain anaerobic conditions without the help of impervious B horizons. (6) In the face of continuous anaerobic conditions, the iron-cementing agents of the placic B horizons become reduced and removed in the groundwater. (7) Organic acids have lowered the *p*H and conditions are right for

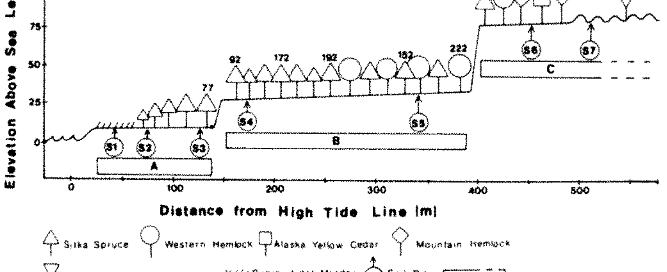

Fig. 2 Cross-section of the Steelhead Transect showing soil pit locations and tree ages across the raised terraces.

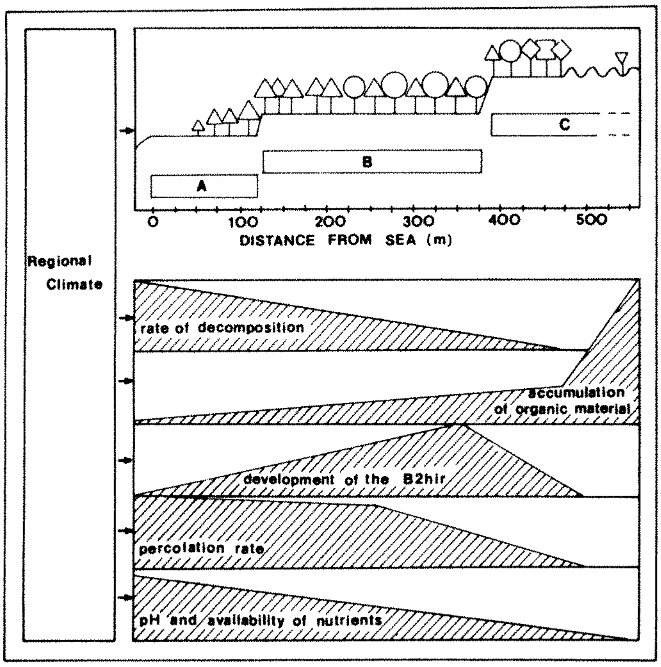

Fig. 3 A model of bog formation near Lituya Bay, South East Alaska.

the succession of bog vegetation onto a surface which once supported a well drained spruce forest.

Along this chronosequence of marine terraces, forest paludification is seen to accompany the development of spodosols. Iron cementation of B horizons, thickness of organic horizons, and hydraulic conductivity in these soils suggest a causative role for placic horizons in the paludification process. Other possible mechanisms of bog formation such as lake-infilling or the presence of impermeable parent material can be eliminated as alternative causes of paludification at this site. The spodosols responsible for paludification disappear in the anaerobic conditions occurring once the bog is established. Hence, little evidence for a pedogenic origin is available under existing bogs; a surface chronosequence seems necessary to document this process.

The role of soil development in peatland formation has been mentioned but seldom documented in the literature, and never previously assigned a major role in widespread paludification[9-11]. The data and model presented above suggest that pedogenically induced bog formation may be more common in South East Alaska and perhaps in other regions of the world than previously recognised.

Behavioural access to short-term memory in bees

Randolf Menzel

Institut für Tierphysiologie, Freie Universität Berlin, Grunewaldstrasse 34, 1000 Berlin 41, FRG

Memory formation proceeds in temporal phases which differ in their effectiveness in controlling subsequent behaviour and in their susceptibility to amnestic treatments[1]. The initial phase of memory formation, frequently termed short-term memory, is generally considered a necessary precursor to long-term memory. However, the course of short-term memory differs widely between animal species and is dependent on experimental procedure. Information may even bypass the short-term phase en route to the long-term one[2,3]. Experiments reported here using honey bees in a behavioural learning situation suggest that the greatest significance of short-term memory is its function as a mode of memory storage which may be altered effectively by new and contradictory information. Freely flying honey bees were presented two colour alternatives and rewarded on first one and then the other in a reversal learning paradigm. Subsequent colour preference was dependent on the interval between the two trials. Several new features of short-term memory are described. It is concluded that a single mechanism of short- to long-term memory transfer cannot account for the observed bimodal interval dependent behaviour. Two mechanisms are proposed.

The experimental procedure resembled that used in previous studies in which freely flying bees were taught to associate food with a colour stimulus[2-5]. Several bees are trained to use a feeding station. A newly recruited bee is marked as the experimental animal and given three pretraining trails to a neutral grey background. Two coloured cards, blue and yellow, are then presented and spontaneous choice test used to establish that the bee has no colour preference. Actual training starts by rewarding the bee once on one of the two colours. Choice behaviour is tested after each reward. The experimental protocol is illustrated in Fig. 1. The first reward is on blue, the second on yellow. A reversed order of colour training gives the same results. Time interval between these trials is varied between 10 s and 10 min. This scheme tests the effects of information initiated by the second trial on that stored during the first. In addition, the effects of temporal separation of the two training trials are also elucidated. Previous results[2,3,5] suggested that the information capacity of short-term memory is both limited and time dependent. Thus variation of the inter-trial interval is a tool to describe short-term memory by a simple behavioural method. Another test after a second reversal learning trial gives information on the stability of these effects. Results are shown in Fig. 2.

Spontaneous choice activity was 50%. The results of learning and reversal learning in the long term are shown by arrows on the right ordinate of Fig. 2; reward duration was 60 s, and the interval between learning and reversal trials 10 min. The time course of interference between initial and reversal learning in the short term is examined by shortening the inter-trial interval. This is accomplished by decreasing reward duration to only a few seconds, making intervals as short as 10 s possible. The percent of choice behaviour has been shown to be independent of both duration and quantity of reward[2,6]. Accordingly, reward durations of 5 and 15 s were used. In both situations there was a dominant reduction in response to the initially rewarded blue colour mark for inter-trial intervals of 3 to 5 min. During this period information from the second trial, the first reversal trial

0028-0836/79/400368—02$01.00

on yellow, dominates the choice behaviour. At both greater and lesser inter-trial intervals choice behaviour was dominated by information from the initial trial on blue.

The results may be interpreted as follows. A learning trial initiates a short- term memory phase, which terminates 3–5 min later, and is followed by a consolidation phase. During the initial period of short-term memory and later with increasing consolidation new and contradictory information does not reach the memory store since the short-term memory and the consolidation process are already occupied by the information coming from the initial trial. In the transitional phase between short-term memory and consolidation, however, the information is more labile; it controls the choice behaviour less accurately[2,3,4] and more readily accepts new and contradictory information. This interpretation is in agreement with previous results[7] in which subjection of bees to electroconvulsive shock, cooling or N_2 and CO_2 narcosis disrupted memory only during the first few minutes after the learning trial. Since response levels in sessions A and B are similar and response functions from the first and second tests are parallel, the inter-trial interval must be the crucial parameter. No additional previously cryptic learning is expressed in the second test.

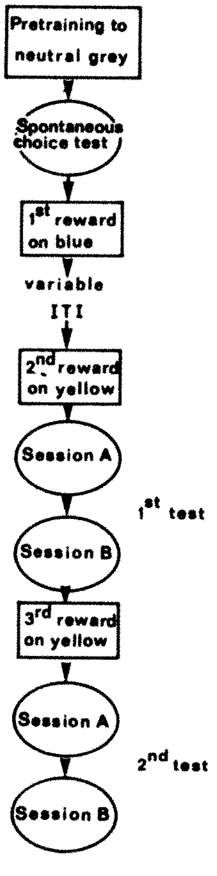

Fig. 1 Experimental scheme. Training sessions are shown in rectangles, and tests in elipses. Single, individually marked foraging bees (*Apis mellifera carnica*) are pretrained to grey cards and then tested for spontaneous choice between blue and yellow cards presented simultaneously. All cards are 7 cm in diameter. The first training reward is on blue, the second on yellow and the third on yellow. ITI (inter-trial interval) is defined as the period between the first and second training trials. Tests consist of two sessions, A and B. Each session lasts 4 min. Time interval between A and B is 3–6 min. Three classes of choice behaviour are monitored: (1) approaching the colourmarks, (2) touching colourmarks with antennae and/or legs, and (3) landing on colourmarks. Approach data are presented here. Touching and landing data show similar results.

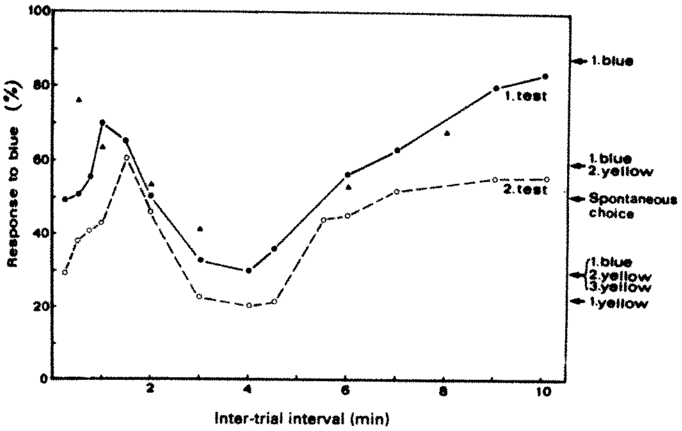

Fig. 2 Inter-trial interval and reversal learning. Results of sessions A and B are similar and, therefore, pooled. Circles are used to illustrate experiments with 5-s reward durations (no. of test animals 57; no. of choices 1,493); triangles represent experiments with 15-s reward duration (14 bees, 278 choices). Arrows on right ordinate: 1. blue, response level after one reward on blue (60-s reward duration); 1. blue 2. yellow, response level after a first reward on blue and a second on yellow (60-s reward duration); 1. blue 2. yellow 3. yellow, response level after a first reward on blue, a second on yellow and a third on yellow (60-s reward duration); 1. yellow: response level after one reward on yellow. In all cases averaged responses of five to eight bees are given. Differences of averaged responses of 15% or more are significantly different at the ≤0.01 level (χ^2 test, 2×2 table).

Our hypothesis does not account for the results obtained when the two training trials are presented within 1 min of each other. In this case, short-term memory should be strongest immediately after the trial[2,5,7]. However, for such short inter-trial intervals the bees switch to the second colour (see Fig. 2, first min of inter-trial interval). Furthermore, if bees are rewarded for 15 s (triangles in Fig. 2) there is not such an early reversal effect. We interpret these findings to indicate an additional mechanism which acts only during the period immediately following the initial trial and 'erases' the information just stored in the short-term memory by the action of new, contradictory information. This mechanism works only if contradictory information arrives in the period immediately following trial. Identical information in massed learning trials adds to each other and can even reach long-term memory directly[3].

Thus there are two temporal periods where reversal of learned behaviour is facilitated: The first ($t \leq 1$ min) is during the assimilation of the short-term phase, the second ($3 < t < 5$ min) is during the transition from short-term to consolidation phases. Information is eliminated most effectively if it has not yet been stored firmly in either the short-term or the long-term phase. The biological function of short-term memory is therefore not limited to that of a precursor for long-term memory; more importantly it is a mode of memory storage which allows for refinement by new incoming information.

Experiments reported here were carried out at the Marine Biological Laboratory, Woods Hole during the tenure of a Rand Fellowship. I thank Dr D. Sandeman, Dr R. Mark and R. Rose for stimulating discussions.

An unusual benzazocine elicits acetylcholine release in the isolated guinea pig ileum

R. J. Valentino, C. B. Smith & J. H. Woods

Department of Pharmacology, University of Michigan Medical School,
Ann Arbor, Michigan 48109

UM-1037 (3-allyl-1, 2, 3, 4, 5, 6-hexahydro-8-hydroxy-6-methyl-3-benzazocine), a benzazocine compound related structurally to the narcotic antagonists cyclazocine and the *N*-allyl analogue of cyclazocine, SKF-10,047, but lacking the 2,6-methano bridge, has been found to produce similar signs in normal rhesus monkeys to those characteristic of the narcotic abstinence syndrome[1]. Narcotic antagonists have been reported to produce contraction in the isolated guinea pig ileum[2,3]. However, only when the ileum has been continuously exposed to morphine or related drugs *in vitro* or has been isolated from animals made dependent on a narcotic, does it contract when an antagonist such as naloxone is added to the perfusion medium[4]. Thus, this preparation has been used as an *in vitro* model of the narcotic abstinence syndrome, and the contraction might be considered an 'abstinence sign'. In the present study, UM-1037 was found to produce a contraction of the guinea pig ileum isolated from normal animals similar to the contraction produced by naloxone in preparations exposed to morphine or related drugs. UM-1037, like naloxone, seems to act by releasing acetylcholine (ACh), because its actions were antagonised by atropine and tetrodotoxin. However, morphine, which is necessary for the naloxone-induced contraction, reversed the effect of UM-1037 on the ileum. Responses to UM-1037 were not altered in the presence of naloxone. Thus, the release of ACh which is produced by this unusual benzazocine in the ileum does not seem to be mediated by the opiate receptor.

The isolated guinea pig ileum was prepared as described by Paton[5]. Segments of ileum were suspended in a Krebs physiological buffer at 37 °C, saturated with 95% O_2–5% CO_2. The buffer contained NaCl, 118 mM; KCl, 4.75 mM; $CaCl_2.2H_2O$, 2.54 mM; $MgSO_4.7H_2O$, 1.19 mM; KH_2PO_4, 1.19 mM; glucose, 11 mM; $NaHCO_3$, 25 mM; hexamethonium Br, 0.07 mM; pyrillamine maleate, 0.125 μM. Resting tension on the tissue was 0.5 g. Tissues were equilibrated for 30–40 min with washes every 10 min. After the equilibration period, ACh, 5×10^{-6} M, was added to the bath to determine the maximum contraction of the tissue. Ten minutes after washing the ACh from the organ baths, cumulative concentration–response relationships were determined for UM-1037 by increasing the concentration of the drug by three-fold increments until a maximum response was obtained. After washout of UM-1037, ACh, 5×10^{-6} M, was added once again to determine whether the contractility of the preparation had changed.

Addition of UM-1037 to the organ bath produced a contraction of the isolated ileum (Figs 1, 2). The maximum contraction produced by UM-1037 was $53.5\pm8.1\%$ of the contraction produced by ACh, 5×10^{-6} M, and ED_{50} for UM-1037 was $5.33\pm0.97\times10^{-6}$ M ($n = 8$). The effect produced by UM-1037 in the isolated ileum not exposed to morphine-like drugs resembles that produced by naloxone in preparations exposed to such drugs[2].

As the contraction produced by naloxone is inhibited by atropine, 10^{-7} M, and tetrodotoxin, 2×10^{-7} M, it is thought to be caused by a release of ACh from postganglionic cholinergic nerve terminals in the myenteric plexus[6]. To determine whether the contraction produced by UM-1037 was due to a similar mechanism, we investigated the effects of atropine and tetrodotoxin on this response. Atropine, 10^{-8} M or 10^{-7} M, added to the organ bath 20 min before UM-1037, antagonised the effects of UM-1037 (Fig. 2). In the presence of atropine, the concentration–response curve for UM-1037 was shifted to the right, and the maximum response was decreased. Tetrodotoxin, 2×10^{-7} M, also blocked the response of the ileum to UM-1037 when added 10 min before UM-1037 (Fig. 2). Although this concentration of tetrodotoxin inhibited the electrically induced contraction of the ileum, it did not affect the response to ACh. The interactions with atropine and tetrodotoxin suggest that UM-1037, like naloxone, produces a contraction of the tissue by releasing a limited store of ACh from cholinergic neurones; this in turn acts on the muscarinic receptors of the intestinal muscle.

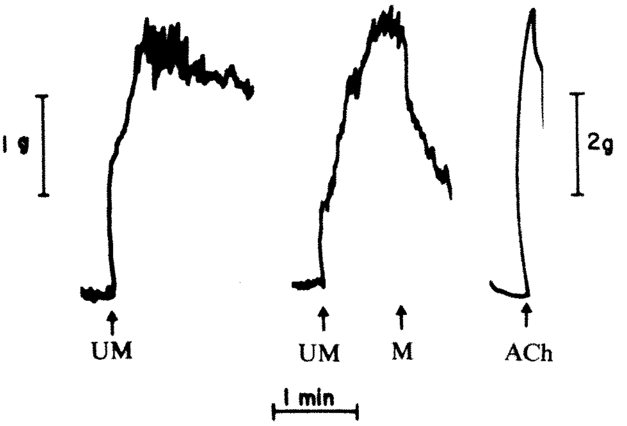

Fig. 1 Effects of UM-1037 on the isolated guinea pig ileum and antagonism by morphine. UM-1037, 3×10^{-5} M, was added to the organ bath at the time indicated by arrow UM. Morphine. 10^{-7} M, was added at arrow M. After washing the preparation, ACh, 5×10^{-6} M, a maximally effective concentration, was added to the organ bath at arrow ACh.

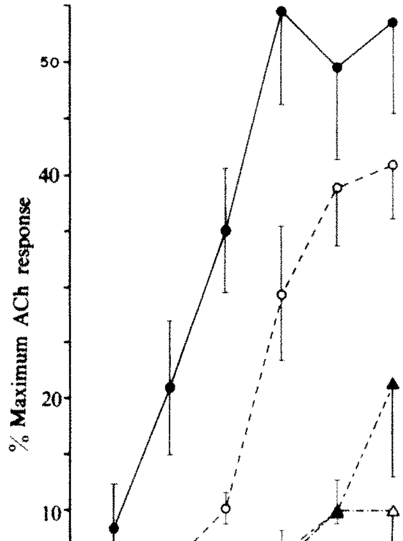

Fig. 2 Antagonism of UM-1037 by atropine and tetrodotoxin. Ordinate, per cent maximum contraction produced by ACh, 5×10^{-6} M. Abscissa, molar concentration. Concentration–response curves for UM-1037 in the guinea pig ileum are shown: eight control ilea (●——●); five ilea in the presence of atropine, 10^{-8} M, added to the bath 15 min before UM-1037 (○---○); five ilea in the presence of atropine, 10^{-7} M, added to the bath 15 min before UM-1037 (▲---▲); three ilea in the presence of tetrodotoxin, 2×10^{-7} M, added to the bath 10 min before UM-1037 (△—·—△). Mean values are given; vertical lines represent s.e.m.

0028–0836/79/400370—03$01.00

Morhpine-like agents inhibit the release of ACh from postganglionic cholinergic nerve terminals in the myenteric plexus of the guinea pig ileum[7,8]. This ability to inhibit ACh release is correlated with the ability to bind with specific receptors in the ileum[9]. To determine whether UM-1037 acts at specific opioid receptors, the interaction between UM-1037 and morphine was studied. Morphine, 10^{-7} M, reversed the contraction produced by a maximally effective concentration of UM-1037 (Fig. 1), and when added to the organ bath before UM-1037, it caused a parallel shift to the right in the UM-1037 concentration–response curve (Fig. 3). To ascertain whether muscarinic receptors in the ileum were affected by this concentration of morphine, the effect of carbachol was studied in the presence and absence of morphine. The ED_{50} values for carbachol alone, and when morphine, 10^{-7} M, had been added 5 min previously, were $1.15 \pm 0.09 \times 10^{-7}$ M ($n = 4$) and $1.37 \pm 0.38 \times 10^{-7}$ M ($n = 6$), respectively. Therefore, morphine reverses the effect of UM-1037 at a concentration which does not block muscarinic receptors. The antagonism of the effect of UM-1037 by morphine as well as by tetrodotoxin and atropine, further indicates that the contraction is due to release of ACh.

The interaction between morphine and UM-1037 may be due to competition at the same receptor site or to opposing effects mediated by interactions of the drugs at different receptor sites. Naloxone, a competitive narcotic antagonist, was used to elucidate this interaction further. Concentration–response relationships for UM-1037, determined 5 min after the addition of naloxone, 10^{-7} M, to the bath, did not differ from those for UM-1037 alone (Fig. 3). This suggests that naloxone and UM-1037 occupy different receptor sites. Naloxone, when added 5 min before morphine, 10^{-7} M, prevented the reversal of the effect of UM-1037 by morphine (Fig. 3). Because naloxone competes with morphine for opiate receptor-binding sites, it is probable that the antagonism of UM-1037 by morphine is mediated through the interaction of morphine with the opiate receptor to decrease ACh release in the guinea pig ileum. These results suggest that the interaction between UM-1037 and morphine does not occur by competition at a common receptor.

To determine whether UM-1037 is a narcotic antagonist, the effect of morphine was studied in the presence and absence of UM-1037. The preparation was coaxially stimulated at 0.1 Hz and supramaximal voltage for 1 h. Then cumulative concentration–response relationships were determined for morphine alone and repeated on other segments of tissue when UM-1037, 10^{-6} M, had been added 5 min previously. UM-1037 decreased the maximum inhibition produced by morphine (24.4% decrease), but did not produce a parallel shift to the right of the morphine concentration–response curve. The ED_{50} values for morphine in the presence and absence of UM-1037, 10^{-6} M, were $2.97 \pm 0.55 \times 10^{-8}$ M ($n = 5$) and $2.33 \pm 0.97 \times 10^{-8}$ M ($n = 5$), respectively. These results are consistent with the concept that morphine and UM-1037 do not compete for common receptors, and that UM-1037 decreases the maximum effect of morphine in the guinea pig ileum through an interaction with another site.

Prior exposure to a narcotic is a requirement for antagonist-precipitated abstinence in animals as well as for the antagonist-precipitated contraction of the isolated guinea pig ileum. The mechanism of narcotic antagonist-precipitated abstinence is generally thought to involve displacement of the narcotic from receptor sites.

In this study, the effects of UM-1037 on the isolated guinea pig ileum were studied. In this preparation, as in the monkey, a sign considered to be characteristic of narcotic abstinence was produced in the absence of narcotic exposure. The effects produced by this drug in the isolated guinea pig ileum resemble those produced by naloxone in preparations exposed to morphine in that release of acetylcholine mediates the contraction of the tissue in both cases. Unlike the naloxone-precipitated abstinence sign in the ileum, the effect produced by UM-1037 is antagonised by morphine.

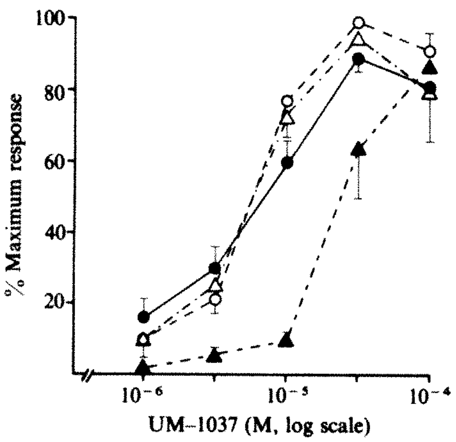

Fig. 3 Interaction between UM-1037, morphine and naloxone on the isolated guinea pig ileum. Ordinate, per cent maximum contraction. Abscissa, molar concentration. Concentration–response curves for UM-1037 in the guinea pig ileum are shown: eight control ilea (●——●); four ilea in the presence of morphine, 10^{-7} M, added to the bath 5 min before UM-1037 (▲---▲); three ilea in the presence of naloxone, 10^{-7} M, added to the bath 5 min before UM-1037 (○---○); four ilea in the presence of both naloxone, 10^{-7} M, added to the bath 10 min before UM-1037 and morphine, 10^{-7} M, added to the bath 5 min after naloxone and 5 min before UM-1037 (△—·—△). Mean values are given; vertical lines represent s.e.m.

A syndrome resembling the narcotic abstinence syndrome has been described in normal rats after the administration of phosphodiesterase inhibitors[11]. This 'quasi-abstinence syndrome' is antagonised by narcotics and potentiated by naloxone. However, UM-1037 does not act like a phosphodiesterase inhibitor. Although morphine antagonises the effect of UM-1037 in the isolated guinea-pig ileum, naloxone does not alter the response to UM-1037. Furthermore, theophylline, a methylxanthine which is a phosphodiesterase inhibitor, does not produce a contraction of the isolated guinea pig ileum, although the methylxanthines do enhance the electrically induced contraction of the ileum[12]. At high concentrations theophylline inhibits the twitch of the stimulated preparation[12]. UM-1037 produces a contraction of the isolated ileum and does not inhibit the twitch at any concentration. Therefore, UM-1037 and phosphodiesterase inhibitors do not seem to share a common mechanism of action in this preparation.

Like UM-1037, nicotine and 5-hydroxytryptamine cause a release of ACh from cholinergic neurones in the isolated guinea pig ileum[12]. Preliminary studies indicate that the actions of UM-1037 on this preparation are not mediated by either nicotinic or tryptaminergic receptors[13,14].

Although the present study suggests that the precipitation of the abstinence syndrome by narcotic antagonists in morphine-dependent ilea and the abstinence-like syndrome produced by UM-1037 in non-dependent ilea involve different receptor sites, it is possible that common mediators or neural pathways are involved in both drug effects. UM-1037 and related compounds may be important in elucidating the mechanism underlying the narcotic abstinence syndrome.

UM-1037 was provided by Dr W. E. Scott (Roche). This study was supported by USPHS grants DA-01474 and DA-00254.

Curare has a voltage-dependent blocking action on the glutamate synapse

Daisuke Yamamoto & Hiroshi Washio

Laboratory of Neurophysiology, Mitsubishi-Kasei Institute of Life Sciences, Machida, Tokyo 194, Japan

---

The skeletal muscle of members of Orthoptera and Diptera receives an innervation which is probably glutaminergic[1–3]. Recent study of the ventral muscle fibres in the larvae of the beetle, *Tenebrio molitor*, has revealed that the transmitter action can be mimicked by the iontophoretic application of L-glutamate to the junctional sites at which the extracellular excitatory postsynaptic potentials (e.p.s.ps) could be recorded (D.Y. and H.W., unpublished observation). Contrary to the evidence favouring glutamate as a transmitter of junctional excitation in insects, some investigators have found that curare (+)tubocrarine, TC), a classic acetylcholine (ACh) antagonist, suppresses the neurally evoked muscle potentials in the fly *Sarcophaga*[4,5], and *Tenebrio*[6]. Here, we have analysed the action of curare on the neuromuscular junction of *Tenebrio* larvae and found that curare blocked the glutaminergic transmission by antagonising the transmitter at the postsynaptic site.

The dissection used has been described previously[7]. The ventral muscle fibres were penetrated by two microelectrodes, one for recording and another for passing current, filled with 3 M KCl and 2 M K citrate, respectively. When necessary, the muscle fibres were voltage clamped using a two-microelectrode method[8]. For focal extracellular recording, electrodes were filled with 3 M NaCl. Although the signals recorded extracellularly could be resolved into single traces on the oscilloscope, a minicomputer (Sanei signal processor 7T07A) was used to obtain a signal averaging so as to improve the signal-to-noise ratio. The iontophoretic electrodes were filled with 1 M solution of monosodium L-glutamate (*p*H 8.0). The e.p.s.ps were evoked by stimulating the innervating nerve close to the segmental ganglion. All experiments were carried out in a low Ca^{2+} saline solution to any minimise movement artefacts accompanying an action potential. The standard bathing saline solution had the following composition (mM): NaCl, 70; KCl, 30; $CaCl_2$, 0.8; $MgCl_2$, 14.2; glucose, 445; HEPES, 5. The *p*H of the solution was adjusted to 7.2 with NaOH.

Curare, when applied to the bathing solution at concentrations higher than 5×10^{-4} M, reversibly depressed the e.p.s.p. amplitude without affecting either the input membrane resistance or the resting potential of the muscle fibre. Simultaneous focal recordings have revealed that the postsynaptic current was substantially depressed but that the presynaptic impulse and the synaptic delay remained essentially unchanged (Fig. 1). The quantum content estimated by the failure method[9] was unaffected by the application of curare (Table 1). These facts indicated that the site of action of curare was on the postsynaptic membrane. The observations do not necessarily mean that the presynaptic terminal of *Tenebrio* neuromuscular junction lacks the ACh receptors reported to be present on the locust junction[10], because curare failed to affect transmitter release even in the locust system unless it was applied simultaneously with ACh[10,11].

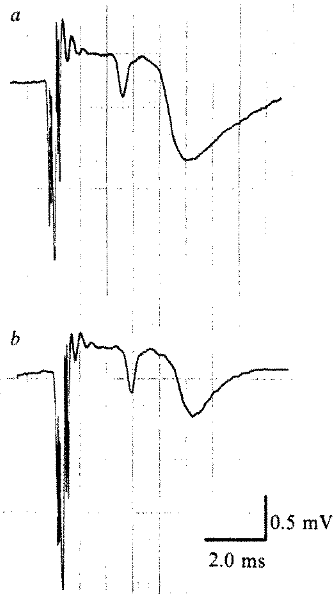

Fig. 1 The nerve terminal action potential and the e.p.s.p. recorded extracellularly from the neuromuscular junction. Records were taken before (*a*) and 5 min after (*b*) bath perfusion of 7.5×10^{-4} M curare. Signals were averaged over 99 trials.

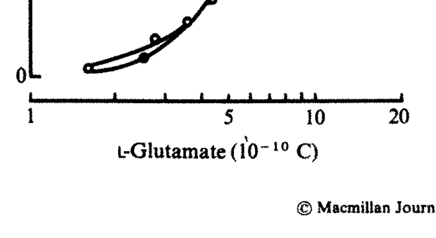
To characterise the curare-induced suppression further, we examined the action of curare on the glutamate potential. We found that the amplitude of the glutamate potential decreased and the time to peak was markedly prolonged after treatment with 5×10^{-4} M curare. One possible explanation for the prolonged glutamate potentials in TC solution is that the L-glutamate molecules ejected must diffuse over a greater distance to reach the sensitive receptors than would be required in normal conditions because some accessible receptors which are distributed on the fibre surface may become unavailable through the action of TC. Both effects of curare on the glutamate potential were fully reversible. Curare also produced a reduction in the apparent maximum of the dose–response curve for glutamate-induced depolarisation (Fig. 2). The non-competitive

Fig. 2 Effect of curare on the dose–response curve to glutamate recorded from a single mealworm muscle fibre: Results are of glutamate-evoked membrane depolarisation measured in control solution (●) and in 7.5×10^{-4} M curare (○).



0028–0836/79/400372—02$01.00

Table 1 Effect of curare on quantum content

Expt	Concentration (mM)	Before TC	During TC	Quantum content ratio (during/before)
1	0.75	2.15	2.03	0.94
2	0.75	1.74	1.56	0.90
3	0.5	1.03	0.90	0.87
4	0.5	1.41	1.82	1.29
Mean and s.e.				1.00 ± 0.098

Quantum content was calculated from the number of failures of extracellular e.p.s.ps. The number of stimuli ranged from 198 to 396; the stimulation rate was 5 Hz.

antagonism has been taken as evidence that the drug blocks ionic channels mediated by the transmitter rather than acting on the receptor itself[12]. Furthermore, there is additional evidence supporting the notion that curare is acting on the glutamate channel. Thus, in contrast to its normal behaviour, the amplitude of the glutamate current under voltage clamp does not increase with hyperpolarisation, but may actually be reduced (Fig. 3). At cholinergic synapses in *Aplysia* neurones[13] and frog muscle[14], curare has been shown to produce a negative slope in the membrane potential–ACh current relationship with hyperpolarisation, but the amplitude of the excitatory postsynaptic current (e.p.s.c.) increased linearly with hyperpolarisation even in the presence of curare ('Manalis effect' (ref. 15)). Contrary to results in these cholinergic synapses, curare influenced the membrane potential–e.p.s.c. relationship in a similar manner to that observed in the iontophoretically induced responses in the present system. Representative families of e.p.s.cs before and during application of curare are shown in Fig. 4. In this respect, the action of curare on the glutamate-mediated junction resembles that of local anaesthetics on the cholinergic synapse. For example, procaine produces a non-linearity of the membrane potential–e.p.s.c. amplitude relationship in the frog neuromuscular junction[16], suggesting that the drug becomes more effectively attached to its binding site in the activated receptor–mediator complex during hyperpolarisation. As in the case of procaine blockade of the cholinergic synapse, curare might combine with the receptor–transmitter complex, thereby 'plugging' the open channel itself[15,17,18]. Alternatively, the present results showing an effect of curare on the e.p.s.c. as well as on the glutamate current may favour a model[19] in which local anaesthetics can bind to the receptors before ACh does.

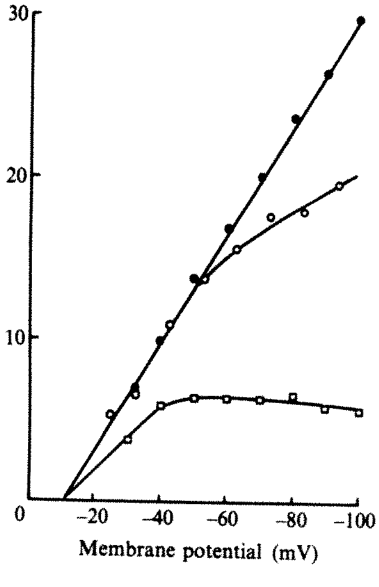


Fig. 3 Voltage dependence of the amplitude of the glutamate current measured before (●) and 5 min after (□) perfusion of 7.5×10^{-4} M curare and 15 min after washing with drug-free saline (○). The recovery after washing is incomplete in this fibre.

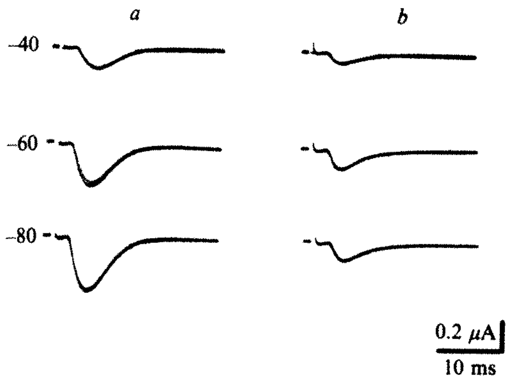

Fig. 4 Excitatory postsynaptic currents recorded at three different holding potentials (indicated at the left side of the each trace) before (*a*) and during (*b*) application of 7.5×10^{-4} M curare. Three successive e.p.s.cs evoked by repetitive stimulations at 0.5 Hz were superimposed on each record. Downward deflections indicate inward currents.

The blockade of non-cholinergic transmission by curare has already been reported in *Aplysia* neurones[20,21]—depolarisations induced by dopamine and serotonin as well as Cl-dependent hyperpolarisation caused by serotonin were suppressed by curare. In addition, K^+-dependent hyperpolarisations induced not only by dopamine and serotonin but also by ACh were completely insensitive to curare. Therefore, it seems possible that curare acted on the ionic channels rather than on the receptors in *Aplysia* neurones.

The present experiments demonstrate that the site of action of curare in *Tenebrio* ventral muscle is on the subsynaptic membrane. However, there is no evidence that curare has similar effects on synapses in other *Tenebrio* muscles. Reports that curare is inactive at synapses on some other insect muscles, such as *Periplaneta*[22] and *Schistocerca*[23], probably reflect a species difference. The results are against the explanation that curare can indirectly depress the muscular electrical potentials by blocking conduction in the motor nerves[24–26]. The study also suggests that results using curare as a pharmacological indicator of cholinergic involvement should be interpreted with caution.

We thank Professor and Mrs Takeuchi for their critical reading of the manuscript, and Miss J. Kaneko for technical assistance.

Recycling of noradrenergic storage vesicles of isolated rat vas deferens

Arun R. Wakade

Department of Pharmacology, State University of New York,
Downstate Medical Center, 450 Clarkson Avenue, Brooklyn,
New York 11203

Del Castillo and Katz established the theory of quantal release of acetylcholine from the neuromuscular junction[1]. The concept was expanded by showing that quanta of transmitter was packaged in, and released from, storage vesicles of the nerve endings. Noradrenaline (NA) is also believed to be stored in, and released from, storage vesicles of the sympathetic nerves. The requirement of Ca for NA release[2] and concomitant secretion of the vesicular enzyme, dopamine-β-hydroxylase[3], on stimulation lends strong evidence to the theory of exocytosis. However, it remains unclear whether storage vesicles after fusing with neuronal membrane to release NA into cleft, are once again reused for further storage and release of NA, or are discarded by the nerve endings. I have investigated this question by making use of the fact that tetraethylammonium (TEA) causes profound facilitation of the overflow of ^{3}H-NA when the sympathetic nerves of the isolated vas deferens are electrically excited[4], and that this excess release is accompanied by a significant reduction in tissue NA content[5]. The principal advantage of the method is that the reduction in tissue NA content is effected exclusively by the exocytotic release of NA from the nerve terminals and easy washout of TEA allows one to study uptake of exogenous NA by the tissue. The results presented here support the hypothesis that NA storage vesicles are recycled.

Male rats weighing 300–400 g were killed by a blow on the head, and the vasa deferentia were removed. Vasa deferentia were placed in 1 ml Krebs solution gassed with 95% O_2–5% CO_2, and incubated at 37 °C for 30 min, and then incubated for 15 min with 0.35 μM ^{3}H-labelled (±)NA (specific activity, 13 Ci mmol^{-1}, Amersham Searle). Following termination of incubation, the tissues were washed three times with Krebs solution over a 30-min period, at the end of which tissues were removed to study either NA content and ^{3}H-NA accumulation or the overflow of ^{3}H-NA upon transmural stimulation as described previously[6]. In the case where repetitive stimulation was used for longer periods, a train of 150 impulses at 5 Hz was delivered every 30 s of 1 min for varying periods of time (80 V, 1-ms duration) from a Grass stimulator, Model S-88. In the case where overflow of ^{3}H-NA was studied before and after TEA and repeated stimulation, the vas deferens was stimulated by a train of 900 impulses at 30 Hz. To obtain net overflow of ^{3}H-NA released by stimulation, the amount of radioactivity spontaneously released within the immediately preceding equivalent time period was subtracted from the total amount released during the stimulation period[6]. Overflow of ^{3}H-NA is expressed as a fraction of the total ^{3}H-NA content of the tissue at the onset of stimulation. Endogenous NA content of the vas deferens was analysed fluorometrically[7] as described earlier[8]. The same method was used to separate ^{3}H-NA and ^{3}H-catechol metabolites from the tissue bathing medium as previously described[6].

As TEA enhances stimulation-induced overflow of radioactivity in the ^{3}H-NA-labelled rat vas deferens by about 20-fold at 5 Hz, as compared to a four- to five-fold increase with phenoxybenzamine[4], TEA was used to study its effect on tissue NA content at rest and during nerve activity. As shown in Table 1 the NA content of right vas deferens exposed to TEA was comparable to that of the contralateral control tissue. Intermittent transmural stimulation of the right vas deferens caused no significant change in the NA content. However, transmural stimulation in the presence of TEA significantly lowered tissue NA content. Figure 1 shows the combined effect of TEA and transmural stimulation on tissue NA content for different time periods. A significant reduction in NA content (27±4%, $P<0.01$) was found after 30 min and the degree of reduction increased with the exposure to TEA and transmural stimulation. A maximum reduction of 87% occurred after 4 h.

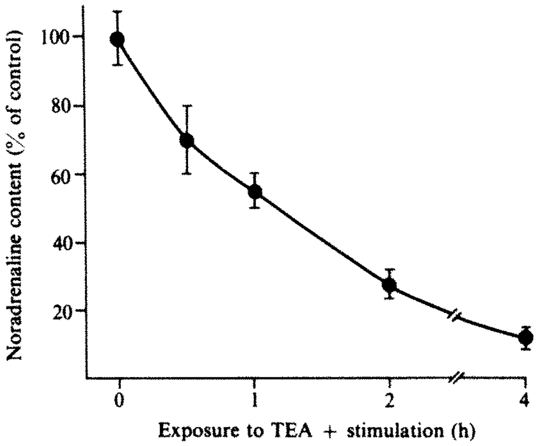

Fig. 1 NA content of the vas deferens various times after exposure to TEA and transmural stimulation. The right vas deferens was exposed to 10 mM TEA plus transmural stimulation (5 Hz, 30 s min^{-1}) for different time periods. The NA content of the treated tissue is expressed as a percentage of that found in contralateral control tissue (11.6±0.1 μg g^{-1}, $n=20$) kept in 10 mM TEA–Krebs solution for a comparable time. Each point, except the 0-h point, represents a mean of 5 observations. Vertical lines show s.e.m.

NA is equally distributed throughout the vas deferens[8]. Therefore, during the course of an experiment the tissue can be cut in several portions, each portion initially having comparable amounts of NA (or ^{3}H-NA). Initial NA and ^{3}H-NA contents present in a small portion of the vas deferens were 13.01±0.75 μg g^{-1} and 4,520±412 c.p.m. mg^{-1}, respectively (Fig. 2).

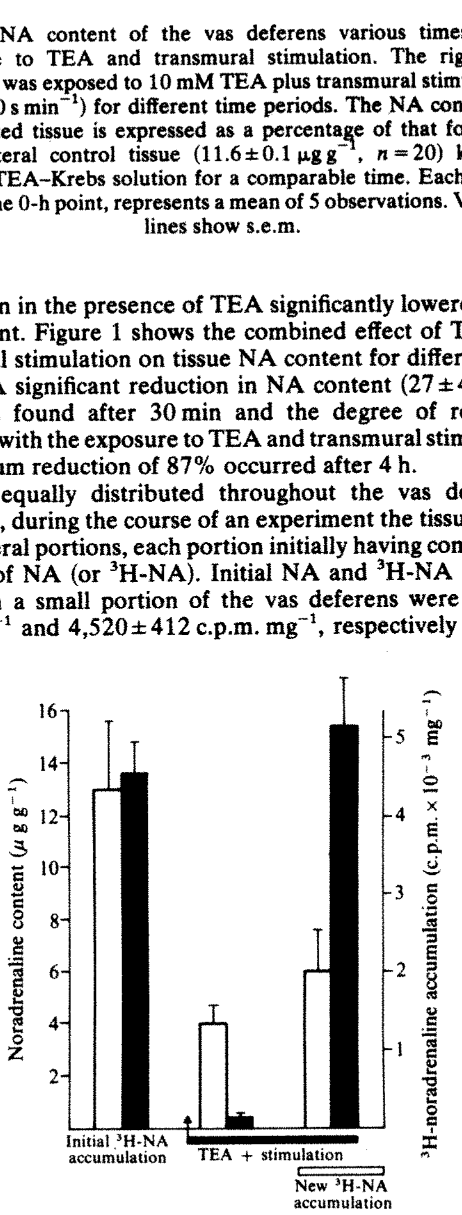

Fig. 2 Depletion and retention of ^{3}H-NA before and after TEA and transmural stimulation for 2 h. NA content (open columns) and ^{3}H-NA accumulation (solid columns) are shown in control tissue (first paired columns), in the same tissue after exposure to TEA plus stimulation for 2 h (Fig. 1) (middle paired columns), and in the same tissue after exposure to TEA plus stimulation for 2 h, and then incubation with ^{3}H-NA (last paired columns). For details see text. Each column represents a mean of 5 experiments. Vertical lines show s.e.m.

Table 1 Effects of TEA and transmural stimulation, separately and together, on NA content of the vas deferens

Experimental conditions	No. of experiments	NA content Control, left vas deferens ($\mu g\ g^{-1}$)	 Experimental, right vas deferens	% Of control
TEA (10 mM, for 2 h)	5	10.06 ± 1.40	12.08 ± 1.70	120 ± 13 (NS)
Transmural stimulation (5 Hz, 30 s min^{-1}, for 2 h)	7	12.08 ± 1.70	12.80 ± 1.0	106 ± 9 (NS)
TEA + transmural stimulation	7	11.40 ± 0.8	2.90 ± 0.40	25 ± 6*

After 30 min equilibration of both vasa deferentia in Krebs solution, right vasa deferentia were exposed to either TEA, transmural stimulation, or TEA plus transmural stimulation for a total period of 2 h. Left vasa deferentia remained in Krebs solution (first 2 groups of experiments) or in 10 mM TEA (the third group) for 2 h to serve as controls. NS, not significantly different from the control.

* $P < 0.001$.

The remaining tissue was subjected to the combined treatment of TEA and transmural stimulation for 2 h. TEA was washed out for 15 min and the tissue was cut into two portions; one was again incubated with ^{3}H-NA and subsequently washed, while the other remained in Krebs solution. TEA and stimulation lowered NA content by about 70%, and the ^{3}H-NA level was 3% of the initial control. Such depleted tissue, when re-exposed to ^{3}H-NA, took up and retained large quantities of ^{3}H-NA. The new accumulation of ^{3}H-NA was comparable to the initial accumulation by the control tissues not subjected to TEA and stimulation.

As maximum depletion of NA occurred at 4 h after treatment with TEA and stimulation (Fig. 1) the accumulation of ^{3}H-NA in such severely depleted tissues was investigated. NA content was lowered from a control value of 9.54 ± 0.79 to $1.24 \pm 0.3\ \mu g\ g^{-1}$, and ^{3}H-NA was undetectable after TEA plus stimulation for 4 h. On re-exposure to ^{3}H-NA, such depleted tissue retained ^{3}H-NA in amounts identical to those found in control tissue before depletion ($4{,}190 \pm 396$ against $3{,}826 \pm 321$ c.p.m. mg^{-1}).

Cocaine was used to determine the sites of new accumulation of ^{3}H-NA by the depleted vas deferens. In the control tissue, 3.6 μM cocaine reduced ^{3}H-NA accumulation by 74% ($3{,}238 \pm 605$ against 862 ± 190 c.p.m. mg^{-1}, $n = 3$). Cocaine had a similar effect on ^{3}H-NA accumulation in tissue initially depleted by TEA and stimulation ($3{,}260 \pm 388$ against 754 ± 173 c.p.m. mg^{-1}, $n = 3$).

Figure 3 shows the results of experiments in which overflow of newly acquired ^{3}H-NA was studied in tissues previously subjected to TEA and stimulation. Following initial ^{3}H-NA incubation and its washout, the overflow of ^{3}H-NA induced by stimulation (30 Hz) averaged 17.9 ± 2.2 ($\times 10^{-4}$). TEA and transmural stimulation lowered ^{3}H-NA levels to such an extent that no overflow from such tissues could be measured. However, on reloading of the tissue with ^{3}H-NA, overflow induced at 30 Hz was almost identical to the initial overflow 18.7 ± 2.6 ($\times 10^{-4}$). The new overflow was depressed by over 90% in the absence of external Ca (Fig. 3*b*). Substitution of 2.5 mM Ca restored the new overflow to almost 75% of the initial control value.

As stimulation alone does not alter tissue NA content over a 2-h period, the amounts released through this method may be replenished by either the synthesis of new NA or uptake of released NA, or both of these mechanisms. With TEA and stimulation NA release must be so great that even accelerated synthesis together with reuptake cannot keep up with the release, resulting in a reduction in tissue NA content. Ca is needed for the TEA-induced facilitation of release during nerve stimulation. Therefore, the depletion of NA content of the isolated vas deferens must be a result of exhaustive exocytotic release of NA. The participation of newly synthesised storage vesicles can be totally excluded in this study, as this cannot be done in the case of the adrenal gland or sympathetic organ *in vivo*, because the hypogasting plexus innervating the vas deferens[8] is not present in the preparation. Although certain procedures reduce the NA content of the isolated tissues, these did not involve the exocytotic release of NA. It was shown that Na deprivation results in reduction in NA content of cat spleen slices[9] and the rabbit heart[10] without requiring external Ca. However, intermittent stimulation of splenic nerves of the dog in the presence of phentolamine caused significant loss of splenic NA content[11].

As it was shown that the amounts of ^{3}H-NA retained by previously depleted vas deferens were almost identical to those retained by control tissues and as cocaine, a well-known inhibitor of neuronal uptake of NA[12], blocked initial and new accumulation of ^{3}H-NA to the same extent, it is believed that the new accumulation occurs predominantly in the sympathetic nerves. If NA taken up by the neuronal membrane is not removed by the storage vesicles, then it is rapidly deaminated by intraneuronal monoamine oxidase[13]. In the present work it was found that even 30 min after washout comparable amounts of ^{3}H-NA were retained by normal and depleted tissues. Therefore, it is assumed that ^{3}H-NA taken up by depleted tissue is retained by the storage vesicles of the sympathetic nerve ending. Strong proof for the idea that the newly taken up ^{3}H-NA is accrued to the storage vesicles is that stimulation releases newly acquired ^{3}H-NA. It is known that if ^{3}H-NA is not present in the storage vesicles, but is accumulated in extravesicular sites in the sympathetic nerves, it is not avavilable for release by electrical stimulation[14]. The fact that newly acquired ^{3}H-NA can be

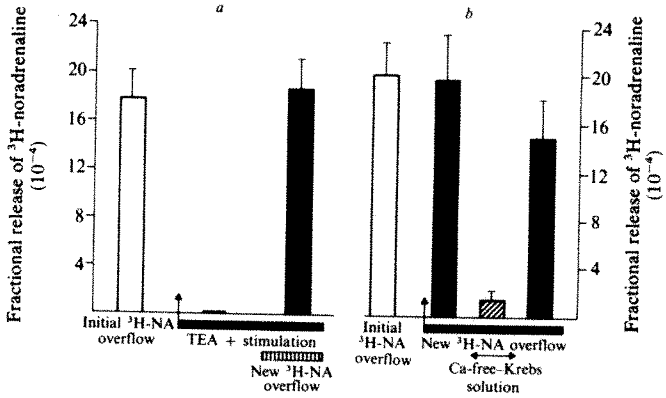

Fig. 3 Overflow of ^{3}H-NA before and after TEA plus transmural stimulation for 2 h. Overflow of ^{3}H-NA was induced by stimulating (30 Hz for 30 s) the initially labelled vas deferens (open column). Overflow of ^{3}H-NE is expressed as fractional release which represents the ratio of the overflow of ^{3}H-NA to that in the tissue at the beginning of the stimulation. The solid column represents the overflow elicited from relabelled tissues subjected to 10 mM TEA plus transmural stimulation in Krebs solution, as described above, then in Ca-free Krebs solution (hatched column), and finally in Krebs solution. *a*, Each column represents a mean of 8 experiments and in *b* represents a mean of 4 experiments. Vertical lines show s.e.m.

released in response to nerve stimulation, and that the new release is Ca dependent, would indicate that the release occurs by exocytosis.

The main question now is whether the same storage vesicles which participate in the storage and release of NA are responsible for the accumulation and subsequent release of ^{3}H-NA. As the maximum depletion of NA stores was 87% after TEA and stimulation, it may be that remaining storage vesicles which did not participate in exocytosis could take over the function of storage and release of the total original population of vesicles. Another possibility is that storage vesicles previously involved in exocytosis can be reused by sympathetic nerve terminals for the purpose of recapturing and releasing new NA.

It has been suggested that the membrane of the large noradrenergic vesicle in nerve terminals may be retrieved after exocytosis in the form of small vesicles. The latter, then, might be the precursors of the functioning small vesicles[15]. In support of such an idea, it has been shown that newly formed small storage vesicles after nerve activity contain significant amounts of dopamine β-hydroxylase, and these vesicles are capable of storing ^{3}H-NA[11]. An alternative suggestion is that after a vesicle fuses with the nerve membrane it becomes nonfunctional and is destroyed by the nerve[16]. Based on the experiments reported here, I feel that noradrenergic storage vesicles of the rat vas deferens can be reused more than once by nerve terminals. However, the lack of recovery of endogenous NA, following its depletion by exhaustive exocytosis, may be an indication that used vesicles lose their ability to synthesise NA and are only capable of storing preformed NA.

This work was supported by USPHS grant HL18601.

The difficulty of working with the intact brain *in vivo* has led to the increasing use of nerve cell cultures in neurobiology. However, dissociated cells cannot be unambiguously identified by morphological criteria before the third week in culture, for it is not until then that the basic morphology and size of neurones become stable so that these and other cell types can be easily distinguished[1]. However, cultured neurones can be identified by various cytochemical techniques based on (1) the detection of neurotransmitters or receptors for transmitters[2–4], (2) the presence of the Thy 1 antigen and the receptor for tetanus toxin, which are present on the membrane of most neurones[5], and (3) the presence in neurones of neurone-specific enolase (NSE), a cytoplasmic enzyme, which can only be identified on fixed specimens[6,7]. Furthermore, other cell types in culture can also be specifically labelled. For instance, antisera to galactocerebroside bind selectively to oligodendrocytes[8], and antibodies to a neural tumour bind selectively to Schwann cells[5,8,9]. We report here the selective interaction of phosphorylcholine-binding myeloma proteins (PC-BMP)[10] with mouse neurones in culture and in suspension. Phosphorylcholine (PC) is found as part of lecithin and sphingomyelin molecules in variable amounts in eukaryotic and prokaryotic membranes, including plasma membranes[11–13].

Dissociated cells from the mouse (C57/B6) nervous system were cultured as previously described[1]. Briefly, spinal cord, dorsal root ganglia or both, were dissected from 12–13-d embryos and cleaned of any adhering tissue. Excised tissue was cut into small pieces, trypsinised (0.25% in Eagle's minimal essential medium (MEM)) and further mechanically dissociated. Cells were seeded (5×10^5 cells per coverslip) on to 12-mm glass coverslips in 24-well plates (Cluster 24, Costar) coated with 0.05% collagen (Calbiochem) in 0.1% acetic acid. Cells were grown under 90% air and 10% CO_2 in bicarbonate-buffered MEM supplemented with 600 mg glucose per 100 ml, 10% heat-inactivated horse serum and, until the cultures reached confluency, 10% fetal calf serum. When confluent (at about 5–7 d), they were exposed for 2 d to 5-fluorodeoxyuridine (Sigma, 1.2 mg per 100 ml) and uridine (3 mg per 100 ml). This treatment, which prevents overgrowth of dividing non-neuronal cells, was repeated 2 weeks later if thought necessary. The medium was changed three times per week. Most experiments were carried out 4 weeks after plating, when the majority of cells could be identified by phase contrast microscopy on morphological criteria. These cultures were fixed with paraformaldehyde (1% for 5 min). Some experiments were carried out on freshly dissociated living cells in suspension.

The myeloma proteins used in these experiments included the following: TEPC 15; MOPC 167 and McPC 603, PC-BMP; XRPC 25, a dinitrophenol-BMP; EPC 109 and UPC 61, inulin-BMPs; XRPC 24, a $\beta(1-6)$ galactan-BMP; and McPC 870, a lipopolysaccharide-BMP which also weakly binds PC[10]. All proteins were IgAκ and were purified by affinity chromatography, with the exception of McPC 870, which was isolated by ion-exchange chromatography followed by gel filtration. Goat anti-mouse IgA antibodies were raised, purified by affinity chromatography and tested as described elsewhere[14,15]. The antiserum was passed over a mixed IgG (MOPC 195, MOPC 70 A, MOPC 173 myelomas)–Sepharose column and then eluted from an IgA (TEPC 15)–Sepharose column. The purified antibodies (GAMα) were coupled to fluorescein by reaction with fluorescein isothiocyanate (FITC)[14] and a fluorescein : protein molar ratio of 4.5 was obtained. Rhodamine-coupled tetanus toxin (RTT) was prepared as described in ref. 16.

Fixed cells were exposed to MPs at concentrations up to 1 mg ml^{-1} for 1 h at room temperature, washed in phosphate-buffered saline (PBS) and incubated in GaMα (0.5 mg ml^{-1}) for 1 h at room temperature. For double-labelling experiments RTT, PC-BMP and GaMα were applied successively, each for 1 h at room temperature. Cells were mounted on glass slides for

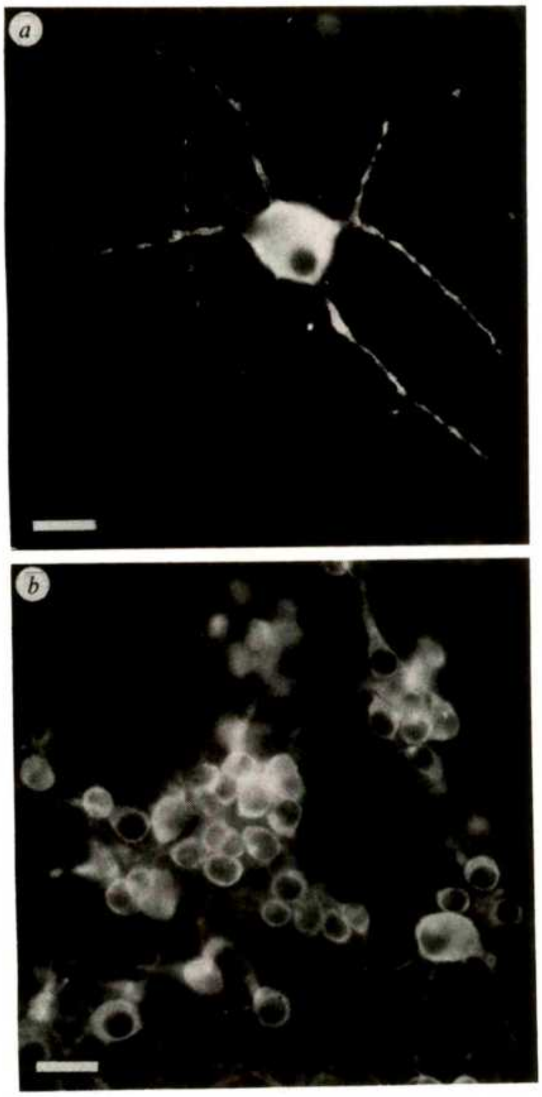

Fig. 1 Immunofluorescence of fixed mouse spinal cord and dorsal root ganglia cells. Four weeks after seeding, cells attached to coverslips were washed with serum-free MEM, fixed in 1% paraformaldehyde in PBS for 5 min at room temperature and washed extensively with PBS. The fixed cells were incubated with affinity-purified PC-BMP, in this case MOPC 167 (1 mg ml^{-1}), for 60 min at room temperature. After washing with PBS, they were incubated with fluorescein isothiocyanate-labelled goat anti-mouse α-chain antibodies (0.5 mg ml^{-1}) for 30 min at room temperature and washed with PBS. The coverslips were mounted on slides with 50% glycerol in PBS and were examined with a Zeiss microscope equipped with epi-illumination. *a*, Only one cell is labelled. It has the typical morphology of a neurone from dorsal root ganglia. The underlying and surrounding cells are negative. Scale bar, 33 μm. *b*, A cluster of smaller spinal cord neurones and one probable dorsal root ganglionic cell are shown. Only neurones are labelled. Cell processes are also labelled, although they are not visible in this picture, where the plane of focus falls on the cell bodies. Scale bar, 40 μm.

observation on a Zeiss microscope equipped with fluorescein and rhodamine optics. NSE was detected on parallel mature cultures as previously described[7]. Double-labelling with PC-BMPs and antibodies to NSE was not possible because of the severe conditions required for the detection of NSE. Live cells were stained for surface antigens immediately after dissociation. A pellet of 10^6 cells was resuspended in 50 μl of MP (1 mg ml^{-1} in PBS) for 20 min at 4°C. Cells were then washed twice, incubated with FITC GaMα (0.5 mg ml^{-1}), washed again, re-suspended in a minimal volume and sealed with a coverslip on a microscope slide.

On mature cultures, all cells with neuronal morphology (that is, phase bright somata, distinct nuclei and process extensions[1]) were stained with PC-BMP MOPC 167 whereas flat background cells (presumably fibroblasts and glial cells) were non-reactive (Fig. 1). A cell type indistinguishable from that stained by MOPC 167 was also stained by antiserum to NSE (a cytoplasmic marker) (Fig. 2) and by tetanus toxin. The latter was used in a double-labelling experiment and all the cells which showed positive fluorescein staining by PC-BMP and FITC GaMα were also stained by tetanus toxin conjugated to rhodamine. However, labelled tetanus toxin also stained some background cells. Identical results were obtained when PC-BMPs other than MOPC 167 were used. Thus, TEPC 15 and McPC 603 behaved exactly like MOPC 167. MP McPC 870 also stained neurones in the same way, although it binds PC with much lower affinity than do the other PC-BMPs[10]. The binding of PC-BMPs to neurones

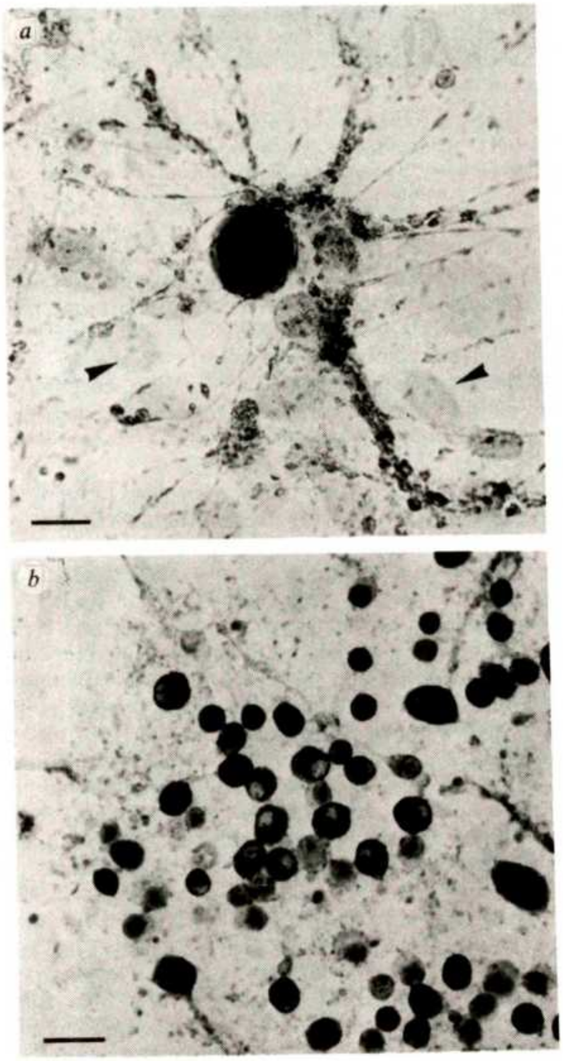

Fig. 2 Immunoperoxidase staining of mouse spinal cord and dorsal root ganglia cells after 4 weeks in culture. Cells were fixed in 4% paraformaldehyde, 1% glutaraldehyde, 0.2% picric acid and 1.5% sucrose in 0.1 M sodium acetate buffer, *p*H 6.0, for 1 h. The fixed cells were washed in 0.05 M Tris-HCl and 0.15 M NaCl, *p*H 6.0, then treated with 0.25% Triton X-100 in the same buffer for 10 min, and washed again. The monolayers were incubated with rabbit antiserum to neurone-specific enolase (1 : 800 in PBS) then with protein A–peroxidase (0.05 mg ml^{-1}) and finally reacted with diaminobenzidine and H_2O_2, as previously described[7]. Monolayers were counterstained with cresyl violet, dehydrated and mounted. Neurones show positive staining for NSE in their soma as well as their processes. In addition to the labelled neurones, the nuclei of several unlabelled cells can be seen (arrowheads). Scale bars, 33 μm(*a*) and 40 μm (*b*).

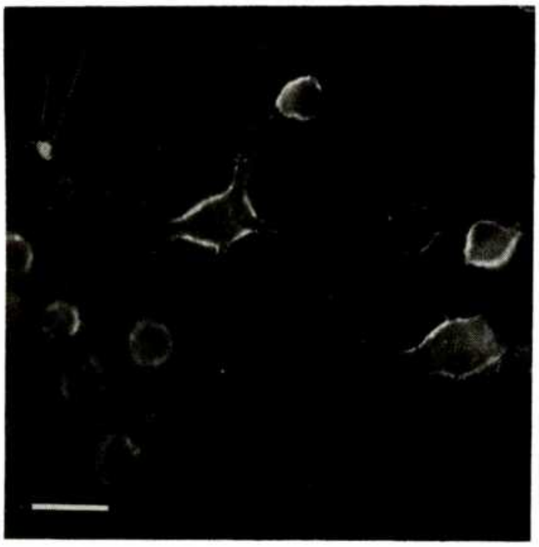

Fig. 3 Immunofluorescence of unfixed mouse spinal cord and dorsal root ganglia cells. After 4 weeks in culture, cells were stained as in Fig. 1 but without fixation. The staining pattern is typical of membrane antigens. Scale bar, 40 μm.

was completely inhibited by a preincubation of the proteins with 10^{-2} M PC, suggesting that PC is part of the determinant. Other MPs of the IgA class (XRPC 24, XRPC 25, UPC 61, EPC 109) did not bind to any cell type in our cultures. MOPC 167 also did not bind the fibroblastic lines, 3T3 4E (ref. 17), cl ID (ref. 18); A9 (ref. 19) and DVGK (a kidney fibroblast-like cell line); a mouse liver cell line, ML311 (established by H. Coon); and a neuroblastoma cell line, N4TGl (ref. 20).

The agreement between our observations and those obtained with accepted markers for neurones indicates that the receptor for PC-BMPs can serve as a marker for neurones in cultured murine nerve cells. It is not yet known whether the antigen is neurone-specific or simply more exposed than on other cell types. An important advantage of our method is that it can be used on live cells (Fig. 3). In addition, with our reagents the labelling was stronger and more specific than labelling with tetanus toxin, which also stained some background cells. It was surprising that although PC is present on the surface of most eukaryotic cells, PC-BMPs reacted only with neurones. Regardless of the reason for this binding, the observation that live cells could also be stained by this method offers the possibility of both identifying and separating neurones from mixed nerve cell populations using methods such as the fluorescence-activated cell sorter[21].

We thank Dr S. Rudikoff for the gift of MPs, Dr H. Coon for various cell lines, Dr D. Schmechel for antiserum to NSE and Dr C. Hardegree for the RTT. We also thank Drs R. Asofsky, D. Brown, M. Potter and M. Raff for discussion and Ms I. Bernard for typing the manuscript. Morphological and biochemical maturation of neurones cultured in the absence of glial cells

B. Pettmann, J. C. Louis & M. Sensenbrenner

Centre de Neurochimie du CNRS, and Institut de Chimie Biologique,
Faculté de Médecine, 67085 Strasbourg Cedex, France

Cultures of isolated neurones offer possibilities for investigating their properties directly in the absence of glial cells. Furthermore, such a culture provides a suitable model for the study of the biochemical and functional maturation of neuronal cells in a well defined molecular environment. Culture techniques of isolated neurones have been developed for cells originating from the peripheral nervous system[1], especially sympathetic ganglion cells[2-5]. Neurones from the central nervous system (CNS) have proved more difficult to maintain in culture in the absence of other cell types[6]. It is only recently that hippocampal neurones from rat embryos have been successfully maintained in culture[7]. We now describe a method for obtaining a pure culture of dispersed neurones from the telencephalon of 8-day-old chick embryos. This method is derived from a technique previously developed in our laboratory[8]. In those culture conditions, the neuronal cells were obtained by dissociation of cerebral hemispheres from 5–7-day-old chick embryos. The cells remained isolated for only 48 h after plating. Beginning with the 3rd day *in vitro*, the cells clumped together and formed large aggregates in which it was quite difficult to identify the cell types. We have improved those culture conditions and have succeeded in cultivating neurones which remained well dispersed for the whole period of culture.

We established the purity of the neuronal preparation by the morphology and by the binding of tetanus toxin, which is the most specific histological marker for neurones in culture[9]. We studied the maturational pattern of these cultures both morphologically and biochemically.

The two main improvements made to obtain cultures of pure dispersed neurones were the use of older embryos, 8–11 days old, and the technique of preparation of the polylysine substrate. Polylysine-coated surfaces were first developed by Yavin[10] and by Letourneau[11] to improve the attachment of the cells to the tissue culture dish. The polylysine solution was prepared immediately before use by dissolving 10 mg of polylysine (Sigma, type IB or VIIB, PM 70,000) in 1 l of a 0.1 M boric acid–NaOH buffer, *p*H 8.4. After sterilisation by Millipore filtration, 10 ml of the polylysine solution were added to each Petri dish (Falcon, 100 mm diameter) for 24 h at room temperature. After removal of the polylysine solution, the plates were rinsed once with 10 ml of Dulbecco's modified Eagle's medium (DMEM, GIBCO), filled with 6 ml of nutrient medium (80% DMEM + 20% fetal calf serum) and placed in a CO_2 incubator (37 °C, 95% air–5% CO_2). The cell suspension was prepared from the telencephalon of 8–11-day-old chick embryos as previously described[8]. The final concentration of the cell suspension was adjusted to 10^6 cells per ml of nutrient medium. Of this suspension, 4 ml, corresponding to one cerebral hemisphere, were added to each prepared dish and the cultures were immediately placed in the incubator. After 3 days incubation the medium was removed and replaced by fresh medium. The

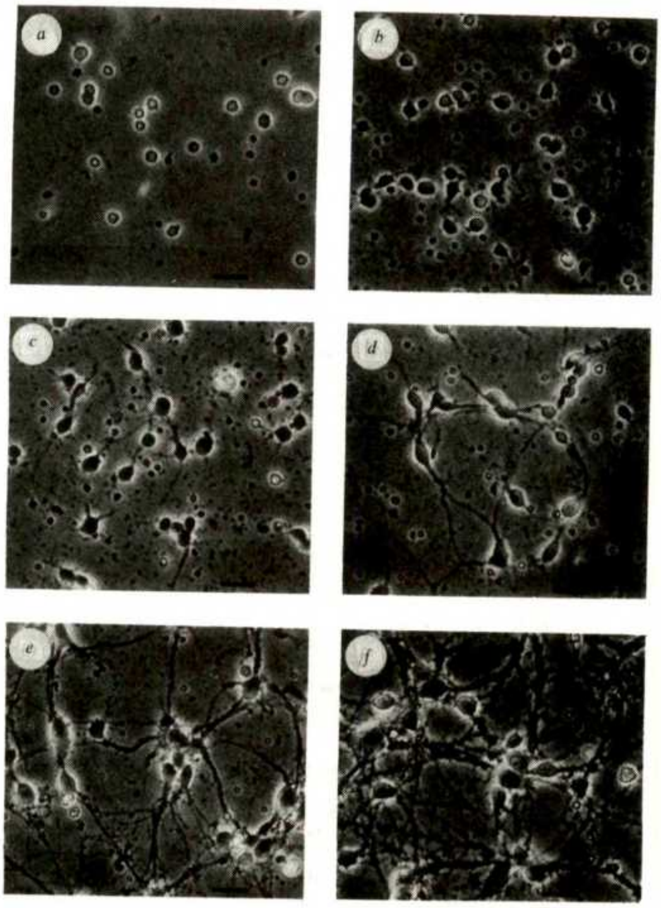

Fig. 1 Morphological development of cultured brain cells dissociated from 8-day-old chick embryos and grown on polylysine-coated Petri dishes. Observations by phase-contrast microscopy. Each bar represents 30 µm. *a*, Initial cell suspension; *b*, 12 h; *c*, 24 h; *d*, 2 days; *e*, 4 days; *f*, 7 days in culture. Detailed culture conditions are described in the text.

cultures remained healthy until the 10th day, as seen by trypan blue coloration.

Figure 1*a* shows that the dissociation of the telencephalon into single cells was complete. The cells adhered very rapidly (within 2–5 min) to the polylysine substrate. After 6 h of incubation, the plating efficiency of the initial suspension was 98 ± 0.5%. The further morphological development of a typical culture is shown in Fig. 1*b*–*f*. The criteria used for the evaluation of the morphological maturation were the size of the cell bodies and the length and complexity of the processes. The outgrowth of processes began between 6 and 12 h (Fig. 1*b*). However, at 12 h, many of the cells showed no indication of neurite formation. Between days 1 and 7, the size of the cell bodies and the number of fibre-bearing cells increased, and the processes spread out and became progressively more ramified, until they formed a dense network covering the entire plate (Fig. 1*c*–*f*).

The most important aspect of our work is the obtention of pure neuronal cultures, as 98% of the cells bind the tetanus toxin (Fig. 2*a*). The absence of glial cells in our cultures could be due partly to the fact that gliogenesis is known to occur later than 8 days during the *in vivo* development of the chick embryo, and partly to the fact that the proliferation in culture of the few glial cells present in the initial cell suspension is inhibited by the polylysine substrate. Non-neuronal proliferation is further prevented by the complete absence of clump formation in our cultures. To estimate the number of glioblasts remaining in the neuronal cultures the cells from a 7-day-old culture were carefully scraped from their dishes, rinsed with serum-free medium, centrifuged at 2,000 r.p.m. for 5 min and transferred to a collagen-coated Petri dish. This substrate is known to favour glial proliferation and maturation. The cells were allowed to grow for 24 h in DMEM containing 20% fetal calf serum and the glial cells present and spread out in the dish were counted under phase-contrast microscopy. The number of glial cells corresponded to less than 0.1% of the total cell population. In any event, our cultures show striking differences from most of those previously described for CNS neurones of embryonic chick or rat (ref. 7 excepted), in which the proliferation of glial cells cannot be entirely inhibited, even in the presence of antimitotic drugs[12,13].

We have correlated the morphological observations with the development of some cellular parameters (Fig. 3). Between the 1st and 3rd day, there is a doubling of the cell number per culture dish and a parallel doubling of the amount of DNA (Fig. 3*a*,*b*). The first change of medium on the 3rd day causes a decrease in the DNA content and cell number. After 4 days these two parameters remain constant. The amount of RNA per plate (Fig. 3*c*) increases until around the 6th day; the amount of protein

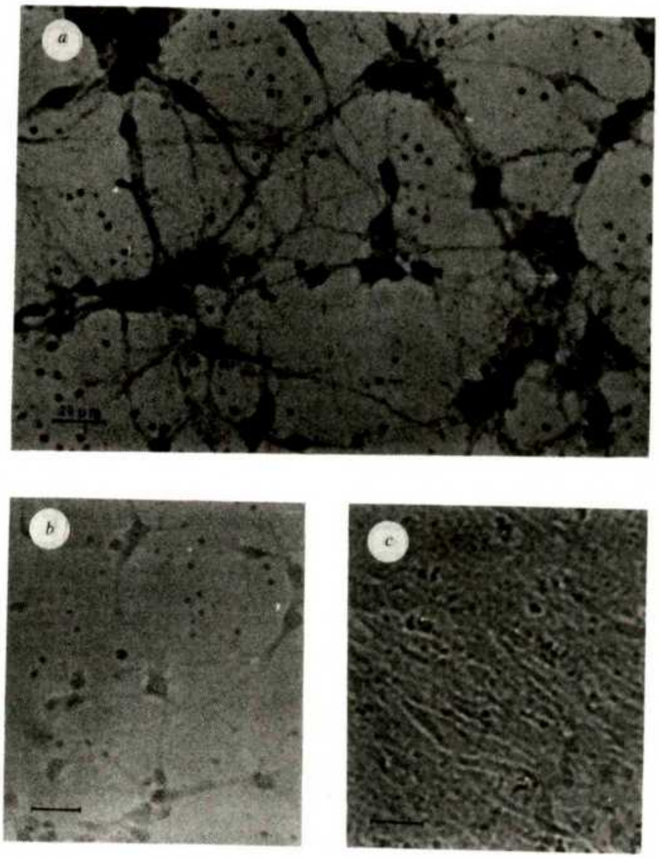

Fig. 2 Immunohistochemical demonstration of tetanus toxin binding sites in the neuronal cultures. *a*, 8-day-old chick embryo cerebral hemisphere neurones cultured for 5 days on polylysine-coated Petri dishes; stained with tetanus toxin, human anti-toxoid gammaglobulins and anti-human gammaglobulins coupled to peroxidase. *b*, 8-day-old chick embryos cerebral hemisphere neurones cultured for 5 days on polylysine-coated Petri dishes; control preparation, stained with tetanus toxin and with anti-human gammaglobulins coupled to peroxidase but without toxoid antiserum. *c*, 20-day-old glial cell cultures, from 15-day-old chick embryo cerebral hemispheres, stained as in *a*. The reaction was always negative in these cultures. Each bar represents 20 µm. The immunohistochemical reaction for the localisation of tetanus toxin binding sites was carried out as described by Mirsky *et al.*[9]. The cultures were rinsed three times with a 0.1 M phosphate buffer, *p*H 7.4, and fixed with a solution of 4% paraformaldehyde and 0.1% glutaraldehyde in 0.1 M phosphate buffer at 4°C for 20 min. After washing, the cells were incubated with 200 µl of tetanus toxin solution (10 $\mu g\ ml^{-1}$ in DMEM), then with either human gammaglobulins or horse antiserum against tetanus toxoid, and finally with either sheep anti-human gammaglobulins coupled to peroxidase (Institut Pasteur) or rabbit anti-horse gammaglobulins conjugated with fluorescein isothiocyanate (Nordic Limited). For each step, the cells were incubated for 30 min at room temperature. Peroxidase activity was revealed by a 0.05% (w/v) solution of diaminobenzidine in 0.1 M phosphate buffer, *p*H 7.4, containing 0.5% (v/v) H_2O_2. In the control preparations, either the tetanus toxin or its antiserum was omitted.

(Fig. 3*d*) increases until the 8th day. These increases occurring after cell proliferation has ceased may be related to the observed increases in the size of the cell bodies and the extension of the processes. Tyrosine hydroxylase activity (Fig. 4) was present in our cultures and showed an eightfold increase between the 1st and 7th days of culture. Dopamine-β-hydroxylase activity was not detected. These morphological and biochemical results indicate the existence of a maturation process, despite the short life span of the cultures.

To our knowledge, as far as the high plating efficiency, the survival of the cells and the purity of the neuronal preparation are concerned, no comparable observations have been reported for central neurones in culture. This culture system was developed with cells originating from the whole telencephalon, but we also obtained pure cultures of neurones from more specific regions of the brain from chick embryos such as striatum, cortex, thalamus, pons–medulla and the optic lobes. Such a culture system will be useful for the study of biochemical and possibly functional maturation of neuronal cells. It will also allow an extensive characterisation of pure neurones, for in the present conditions the neuronal population is not contaminated by glial cells, as is the case with bulk-prepared neurones.

We thank Dr G. Labourdette and Dr S. Gandhour for their comments and suggestions, Dr B. Roth-Schechter for reading the manuscript, Dr B. Bizzini (Institut Pasteur) for the gift of tetanus toxin and anti-toxoid serum, and Dr J. L. Tayot (Institut Merieux) for the gift of human anti-toxoid gammaglobulins.

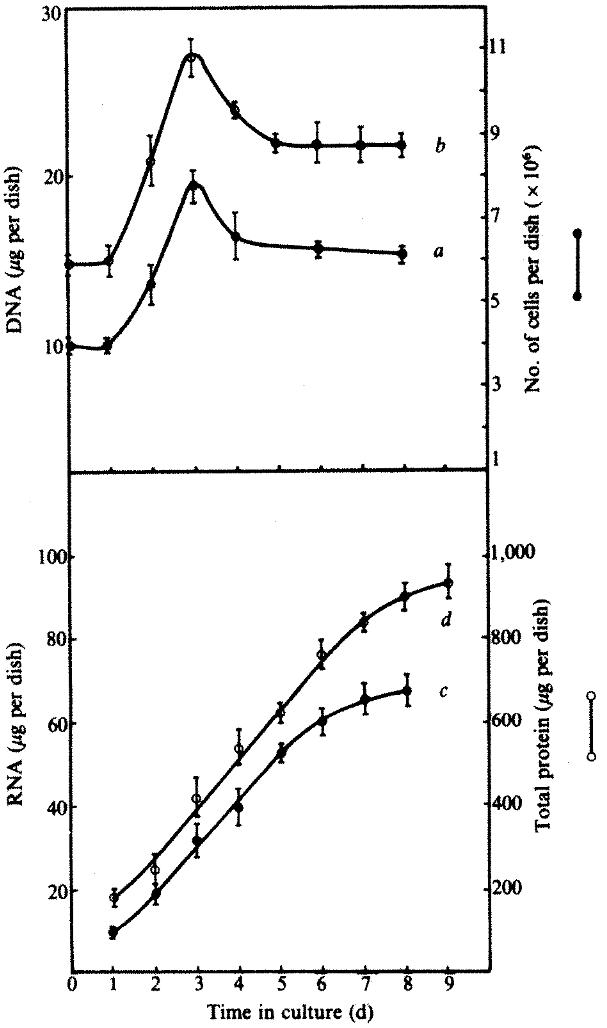

Fig. 3 Biochemical development of isolated neurones in culture. *a*, Number of cells per dish (●). The cells were collected in 10 ml of 0.9% NaCl and aliquots were counted in a Neubauer haemocytometer. Each point represents the mean count ± s.d. of triplicate determinations of three cultures each. *b*, *c*, *d*, Amounts of DNA (○), RNA (●) and total protein (○) per plate, respectively. The cultures were rinsed three times with a 0.9% NaCl solution, collected into 5 ml of 0.9% NaCl and centrifuged at 3,000 r.p.m. for 5 min. The pellet was sonicated twice for ×20 s with a 20-s interval in 1 ml of 2 M NaCl solution containing 5 mM EDTA and 50 mM Tris-HCl (*p*H 8). DNA was determined by the method of Burton[14], RNA by the method of Mejbaum[15] and total proteins by the method of Lowry[16]. Each point represents the mean value ± s.d. of triplicate determinations of six cultures each.

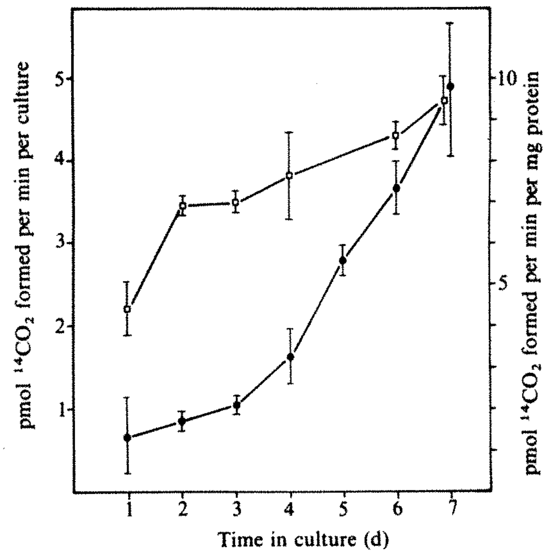

Fig. 4 Developmental pattern of tyrosine hydroxylase (TH) activity in cultures of 8-day-old chick embryo cerebral hemispheres, grown on polylysine, expressed per mg protein (□) and per culture (●). For the determination of TH activity, the cultures were collected in 50 μl of 0.05 M Tris, *p*H 6.0 (acetate), containing 0.2% Triton X-100, homogenised in glass microhomogenisers and centrifuged for 15 min at 12,000*g*. TH activity was assayed on 10 μl (corresponding to 15–40 μg protein) of this supernatant, by the $^{14}CO_2$-trapping method described by Waymire *et al.*[17], with slight modifications. The final concentrations of the incubation mixture were as follows: 0.17 M sodium phosphate buffer (*p*H 6.2), 0.8 mM $FeSO_4$, 0.3 mM pyridoxal phosphate, 30 units ml^{-1} catalase (Boehringer), 0.2 units μl^{-1} dopa decarboxylase (1 unit = 1 nmol $^{14}CO_2$ formed per min) prepared from pig kidney[17], 8.0 mM $DMPH_4$ (Aldrich), 30 mM 2-mercaptoethanol and 150 μM L-[1-^{14}C]-tyrosine (specific activity: 50 mCi $mmol^{-1}$; Amersham). The reaction was carried out for 20 min at 37°C in tubes sealed with rubber injection vial caps. A plastic well was suspended from the rubber injection stopper, which contained 100 μl Protosol (Packard) to trap $^{14}CO_2$ formed during the assay. The reaction was stopped by injecting 100 μl of 3M H_2SO_4 and the tubes were replaced for an additional period of 20 min at 37°C. The Protosol was transferred to counting vials containing 10 ml of Monophase 40 scintillation liquid (Packard). The counting efficiency was 95%. Each point represents the mean value ± s.d. of 8–10 cultures from 3 different experiments. For the determinations of dopamine-β-hydroxylase activity, the cells were homogenised in 5 mM Tris-HCl buffer (*p*H 6.5) containing 0.1% Triton X-100 and the homogenate was assayed according to Bouclier *et al.*[18].

Properties of haematopoietic stem cells surviving 5-fluorouracil treatment: evidence for a pre-CFU-S cell?

G. S. Hodgson & T. R. Bradley

Biological Research Unit, Cancer Institute, 481 Little Lonsdale Street,
Melbourne 3000, Australia

The spleen colony assay of Till and McCulloch[1], which is a clonal assay[2], is considered to be a measure of the stem cell content of haematopoietic tissue. Stem cells are a heterogeneous population[3–6] with respect to their capacity to generate further stem cells (assayed as colony-forming units in spleen, CFU-S) and progenitors of red cells, granulocytes, macrophages and platelets. It has been suggested that stem cells are organised for use according to their generation age[5,6]. There is evidence to indicate that drugs such as hydroxyurea (HU) and 5-fluouracil (5-FU), which preferentially eliminate proliferating cells, spare non-cycling stem cells which have a high capacity to generate other stem cells[6] and progenitors of granulocytes and macrophages[6] as well as megakaryocytes[7]. We show here, however, that the CFU-S content of haematopoietic tissue is not an adequate predictor of the capacity of that tissue to repopulate bone marrow of a lethally irradiated host. Furthermore it appears that haematopoietic stem cells are not only heterogeneous with respect to their capacity to generate other stem cells and progenitors of haemic cells in the spleen but also differ in their capacity to 'home' to either the bone marrow or spleen. The evidence suggests a class of 'primitive' haematopoietic stem cell (pre-CFU-S) that accumulates in the bone marrow to give rise to cells capable of growing in spleen.

During studies of the properties of the haematopoietic stem cells that survive 5-FU treatment we observed that the number of colonies per spleen, in irradiated mice which had been injected with bone marrow from 5-FU treated donors (FUBM), showed a marked increase between 8 and 14 days after irradiation (Fig. 1*a*). The spleen weights of irradiated mice injected with FUBM also showed a remarkable increase between days 12 and 14 (Fig. 1*b*). In contrast, spleen colony counts remained constant as had been previously noted[8], and spleen weights only increased slightly, in mice injected with normal bone marrow (NBM).

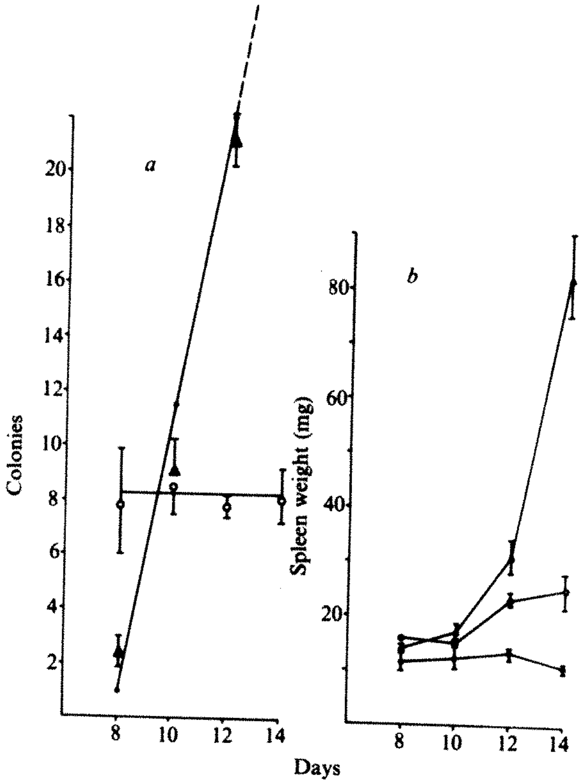

Fig. 1 *a*, Colony counts plotted against time. Bone marrow donors were 10 normal 10–12-week-old (BALB/c × C57BL/6)F_1 male mice or 10 F_1 mice which had been injected intravenously 4 days previously with 5-FU 150 mg per kg. Groups of 10 850R X-ray irradiated F_1 mice, injected with either normal BM, FUBM or uninjected controls were anaesthetised with ether and then killed by cervical dislocation at 8, 10, 12 or 14 days after irradiation, the spleens were removed and fixed in FAA (formalin/acetic acid/alcohol solution) for 24 h then formalin *p*H 7.4. Colonies were counted (using a dissecting microscope ×16.5 magnification). The linear correlation coefficient *r* was 0.8937 for colony counts against time, for FUBM injected mice and 0.1201 for NBM-treated mice. The slope (colonies per day) was 5.33 ± 0.62 for FUBM treated mice and not significantly different from zero for NBM treated mice. *b*, Weights of fixed spleens of mice injected with normal bone marrow or with bone marrow removed 4 days after 5-FU injection. ▲, FUBM injected mice; ○, NBM injected mice; ●, X-ray irradiation controls.

In other experiments using marrow of hydroxyurea-treated donors whose CFU-S have a higher than normal CFU-S generating capacity[6], the phenomenon of time dependence of spleen colony counts was also observed although to a lesser

Table 1 CFU-S[1] and GM-CFC[9] content and marrow (MRA) and spleen (SRA) repopulating ability of femurs and spleen of X-ray irradiated female (BALB/c × C57BL/6)F_1 mice injected with either normal bone marrow (NBM) or marrow obtained from donors injected with 5-FU 1 day previously (FUBM)

		Day 13

* The dose of CFU-S in NBM is estimated from a colony count made on day 10 of spleens obtained from irradiated mice injected with 0.0025 femur obtained from normal mice. GM-CFC content was calculated from the mean of five replicate dishes plated with an appropriate aliquot of a pooled femoral marrow cell suspension from 10 mice. † No colonies were seen in five dishes plated with 1/100 of a femur of marrow from irradiation control mice. ND, not determined.

0028-0836/79/400381—02$01.00

degree ($r = +0.7961$; slope 3.2 colonies per day) than in the 5-FUBM experiment.

Our results indicate that estimates of CFU-S content of marrow suspensions based on a 10-day spleen colony count are not meaningful where the colony count is varying with time. It is as if the haematopoietic stem cells which survive 5-FU preferentially accumulate in the marrow where they give rise to large numbers of CFU-S, some of which then migrate to the spleen where they give rise to delayed colony development.

In relation to bone marrow-seeking stem cells we have repeatedly observed (see, for example, Table 1) that irradiated mice injected with FUBM (from mice 1 to 4 days after FU treatment), had few (13–22) colonies in the spleen but had a higher content of GM-CFC and CFU-S in their femurs at day 13 than mice injected with suspensions of NBM containing about 200 CFU-S. The interpretation of the assay for CFU-S content of cell suspensions obtained from irradiated mice injected with FUBM was not complicated by a change of spleen colony counts in the secondary irradiated recipients between days 10–14. Marrow from mice injected with a bone marrow suspension taken 1 day after 5-FU injection, which produced only 1.7 spleen colonies at day 10, and 13 at day 13, contained four times more CFU-S and six times more GM-CFC than that of mice injected with a dose of normal bone marrow containing 197 CFU-S (Table 1). The ratio of the CFU-S content of spleen to the colony count at day 13 was 100:1 for mice injected with FUBM and 20:1 in mice injected with NBM (calculated value based on CFU-S dose). The ratio GM-CFC: average spleen colony was 10,000:1 and 1,000:1 for FUBM and NBM respectively.

The marrow (MRA) and spleen (SRA) repopulating ability of marrow cell suspensions prepared from X-ray irradiated recipients injected with either NBM (X+NBM) or FUBM (X+FUBM) was evaluated by injection of cell suspensions into secondary irradiated recipients and measuring the GM-CFC content of femurs and spleen on day 13. The results (Table 1) are expressed as GM-CFC per organ per femur injected. Mice injected with marrow from X+FUBM had ~14 times more GM-CFC in femora and 3 times more in spleen than those injected X+NBM marrow. If one takes 1 femur ≃ 1/20 of total marrow, it can be seen that X+FUBM marrow generates many more GM-CFC in marrow than in spleen, while that from NBM marrow generates as many spleen and bone marrow GM-CFC in secondary X-ray irradiated recipients. Results of primary and secondary transplants show that 'stem' cells, efficient in marrow repopulation are affected minimally, if at all, by a dose of 5-FU that reduces cells capable of forming colonies in spleen at day 10 ('10 day CFU-S'), to about one-thousandth of that of normal.

The non-cycling marrow repopulating stem cells which survive 5-FU treatment are associated with a special class of primitive progenitors, which can form very large colonies (containing 5×10^4 cells) of macrophages in agar after 10 days of culture[10]. These progenitors may prove to be the best '*in vitro*' indicator of the marrow repopulating ability of suspensions of haematopoietic cells.

We thank Elizabeth Elms and Christine Morrison for assistance.

Erythropoietin-stimulated erythropoiesis in long-term bone marrow culture

J. F. Eliason, N. G. Testa & T. M. Dexter

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester, UK

The proliferation of multipotential haematopoietic stem cells (CFU-S) is possible in some long-term bone marrow cultures[1–3]. Granulocyte and macrophage progenitors (CFU-C)[2] and megakaryocyte precursor cells (CFU-M)[4] are present in these cultures and undergo full development into mature cells[5–7]. In contrast, while immature erythroid progenitors ('early' BFU-E) are maintained in long-term culture, none of the more differentiated progeny (CFU-E) have been detected, and no morphologically recognisable erythroid cells have been observed[8–11]. We now describe a modified culture system in which the 'early' BFU-E develop into 'late' BFU-E in response to added erythropoietin. Further maturation of these cells into CFU-E and non-nucleated erythrocytes can be achieved by mechanical agitation of the long-term cultures or by transferring the cells into dishes which do not allow cell attachment to occur.

One reason for our previous failure to detect erythroid development in erythropoietin-stimulated long-term marrow cultures[8,9] could be the presence of horse serum in the growth medium used to establish the cultures, which may be inhibitory for erythroid colony growth[11]. On the other hand, fetal calf serum (FCS), which is usually used for the clonal assay of erythroid progenitor cells in semi-solid media, is defective in its ability to stimulate the formation of a competent haematopoietic inductive micro-environment *in vitro* (including endothelial cells, fat accumulating cells and macrophages)[3] and therefore in its ability to sustain *in vitro* haematopoiesis. We have taken advantage of the recent finding that the addition of hydrocortisone to FCS will support maintenance and proliferation of CFU-S and CFU-C in culture (perhaps by influencing the formation of fat accumulating cells in the adherent layer)[12].

The lack of erythropoiesis in long-term marrow cultures may also be related to the finding that the progression from 'early' BFU-E to haemoglobin synthesising cells in erythropoietin-stimulated cultures may require some form of semi-solid support (such as methylcellulose) in the medium[13]. Perhaps the role of methylcellulose in these cultures is to prevent the cells from settling and subsequently attaching to the bottom of the culture dishes. We have used two different approaches to prevent cell adherence in these experiments. The first method was to transfer the cells from the long-term marrow cultures to plastic Petri dishes designed for bacterial culture. Preliminary investigation had indicated that a much smaller proportion of the long-term culture cells will attach to these dishes as compared with standard tissue culture dishes. Our second approach was to place the established long-term cultures on a mechanical shaker to prevent attachment of the erythroid progenitor cells by physical means.

The long-term cultures were established with pooled femoral marrow cells (from 10-week-old male B6D2F$_1$ mice) suspended at a concentration of 1.3×10^6 cells per ml in alpha medium with nucleosides (GIBCO Bio-Cult) supplemented with 25% FCS (Flow), 1% bovine serum albumin (BSA; Path-o-cyte 7, Miles), 10^{-4} M 2-mercaptoethanol (BDH), 7×10^{-6} M human transferrin (Sigma) fully saturated with iron, 10^{-7} M sodium selenite and 10^{-6} M hydrocortisone-21-sodium succinate (Sigma). Aliquots of 10 ml of cell suspension were put into tissue culture flasks (Sterlin), gassed with 5% CO_2 in air and incubated at 33 °C. The cultures were 'fed' at weekly intervals by removing

Long-term culture groups: *A*, control; *B*, erythropoietin at week 2; *C*, adherent and suspension cells transferred to Petri dishes at week 2 without erythropoietin; *D*, same as *C* with erythropoietin; *E*, suspension cells transferred to Petri dishes at week 2. For erythroid colony assays, cells were cultured at $1\text{–}2 \times 10^5$ cells ml^{-1} in alpha medium supplemented with 0.9% methylcellulose, 16% FCS, 0.9% bovine serum albumin, 10^{-4} M 2-mercaptoethanol, 7×10^{-6} M transferrin, 10^{-7} M Na_2SeO_3 and 3×10^{-5} M egg lecithin. Four 0.25-ml aliquots of each cell suspension were plated in the wells of Costar (FB-16-24-TC) tissue culture clusters and incubated at 37 °C in a fully humidified atmosphere of 5% CO_2 in air. Colonies derived from day 2 and day 4 CFU-E (1 or 2 clusters of haemoglobin containing cells) and day 4 BFU-E (3 or more clusters) were grown in the presence of 0.5 U ml^{-1} sheep plasma erythropoietin (step III; Connaught). The assay cultures for day 10 and day 14 BFU-E contained 1.8 U ml^{-1} step III erythropoietin and burst feeder activity as supplied by 1×10^6 irradiated cells (15 Gy from a ^{137}Co source)[15]. The results are expressed as the mean ± 1 s.d. ND, not determined.

half the growth medium and replacing it with fresh medium. After 2 weeks of incubation (to allow an adherent layer to develop), 15×10^6 freshly isolated, syngeneic bone marrow cells were added. This time was taken as week zero. At week 2, duplicate cultures were treated according to the following protocols: *A*, control long-term cultures; *B*, erythropoietin-stimulated long-term cultures; *C*, suspension and adherent cells replated in bacterial Petri dishes; *D*, replated suspension and adherent cells with erythropoietin; and *E*, replated suspension cells alone with erythropoietin. The control cultures (*A*) were fed in the usual manner with no further additions. Erythropoietin-stimulated cultures (*B*) were given 10 units of highly purified human urinary erythropoietin which was a hydroxylapatite fraction with a specific activity of 70,000 U per mg of protein. The level of erythropoietin was maintained at 1 U ml^{-1} through week 4 by further addition of erythropoietin with each medium change. Groups *C* and *D* were set up by removing half the suspension cells in growth medium and all of the adherent cells from a third set of long-term cultures (*C + D*) and mixing them with an equal volume of fresh medium. Aliquots of 5 ml were plated in 60-mm diameter bacterial Petri dishes (Sterilin) without (*C*) and with (*D*) 1 U ml^{-1} highly purified erythropoietin. The final group (*E*) contained suspension cells alone from the 2-week-old long-term cultures, diluted with an equal volume of fresh medium, and plated in Petri dishes with 1 U ml^{-1} erythropoietin. The secondary cultures (*C–E*) were re-fed after 1 week by removing half the medium and replacing it with fresh medium. Pooled suspension cells from the long-term cultures were assayed before treatment at week 2, and after treatment at weeks 3 and 4, for erythroid progenitor cells in a modification of the methylcellulose system originally described by Guilbert and Iscove[14,15].

The results of the erythroid colony assays are given in Table 1 and the morphological composition of the cultures at week 3 is shown in Table 2. The 'early' BFU-E (colonies scored at day 10 or day 14) are present in the erythropoietin-treated long-term cultures (*B*) up to week 4 at levels comparable to those found in the control cultures (*A*), as are the numbers of CFU-S (data not shown). The erythropoietin-treated cultures also had significant numbers of intermediate erythroid progenitors, 'late' (day 4) BFU-E and day 4 CFU-E, at weeks 3 and 4, whereas there were essentially none in the control cultures at these times. However, very few day 2 CFU-E or morphologically recognisable erythroid cells were detected in the intact erythropoietin-stimulated long-term cultures. In contrast, the erythropoietin-treated, replated cultures (*D* and *E*) contained many day 2 CFU-E and benzidine-positive erythroid cells including non-nucleated cells were present at week 3.

Since erythropoietin stimulated the formation of haemoglobin-containing cells when long-term culture cells were transferred to bacterial Petri dishes, it was of interest to find whether erythroid maturation could occur in the intact long-term

6	0	17.2	0	0	0	95	4	0	–
	0.5	24.0	20±5	15±2	0	64	6	30	+

The cultures were established in Fischer's medium supplemented with 25% FCS and 10^{-6} M hydrocortisone. Four weeks after the second inoculum of bone marrow cells was added, 10 units of sheep plasma erythropoietin (step III) were added to two of the four 10-ml cultures which were transferred to a 37 °C incubator and were placed on a tilting platform shaker (Luckham Ltd). The clonal assays for erythroid progenitor cells were performed as described in Table 1 legend.

cultures if they were mechanically agitated. The results of the shaker experiment are shown in Table 3. After 1 week (week 5) the erythropoietin-treated cultures had high numbers of progenitors capable of giving rise to erythroid colonies at day 4, but no morphologically recognisable erythroid cells were detected in the long-term cultures at this time. On the other hand, by week 6, appreciable numbers of day 2 CFU-E were present in the treated cultures and there were also significant numbers of benzidine positive-erythroid cells. The apparent delayed development of erythroid cells in this experiment, after 2 weeks incubation as compared with only 1 week in the previous experiment (Table 1), is probably due to the impure sheep plasma erythropoietin used in this experiment. This preparation of step III erythropoietin (lot no. 3023-1) may be toxic to the late erythroid progenitors since there are decreased numbers of day 2 erythroid colonies formed by freshly plated marrow cells at erythropoietin concentrations above 0.5 U ml^{-1} in the methylcellulose assay system (data not shown).

Thus we have shown that the addition of erythropoietin to long-term cultures will induce the production of intermediate erythroid progenitors, day 4 BFU-E and CFU-E. However, erythropoiesis seems to be blocked at this stage of maturation because no day 2 CFU-E or morphologically recognisable erythroid cells are found. Transfer of the long-term culture cells to an environment where cell adherence is inhibited allows further maturation of the cells, although there is a rapid decline in the precursor populations as demonstrated by the absence of day 10 and day 14 BFU-E at week 4 (groups *C–E* in Table 1). The latter effect is presumably due to the lack of an effective inductive environment (presumably supplied by the adherent layer in the long-term cultures). The presence of the adherent layer in the long-term cultures is not, of itself, inhibitory to erythroid development, as haemoglobin-containing cells are formed in erythropoietin-treated long-term cultures which have been incubated on a mechanical shaker.

We propose a mechanism for the block in erythroid maturation in the epo-stimulated long-term cultures which involves the erythroid precursors becoming adherent as they mature to the CFU-E stage. The potentially adhering property of late erythroid progenitors is supported by the finding that they are retained on nylon fibre columns[16]. The adherent nature of these cells may be involved in the formation of erythroid islands which can be found in bone marrow and other sites of active erythropoiesis[17,18]. We propose that if, *in vitro*, these cells adhere to unfavourable surfaces (and the adherent layer in the long-term cultures of the tissue culture flask, may be such) further maturation will not occur. On the other hand, if they are prevented from attaching to such surfaces then erythropoiesis can continue.

This work was supported by grants from the MRC and the Cancer Research Campaign. We thank M. Booth for technical assistance, Professor Lajtha for critical review of the manuscript, and Dr Eugene Goldwasser for providing purified erythropoietin. T.M.D. is a Fellow of the Cancer Research Campaign.

Vascular endothelial and smooth muscle cells in culture selectively release adenine nucleotides

J. D. Pearson & J. L. Gordon

ARC Institute of Animal Physiology, Babraham, Cambridge, UK

Endothelial cells in culture can modulate platelet aggregation and vascular tone, in part by producing prostacyclin (PGI_2)[1,2], a powerful vasodilator and inhibitor of platelet aggregation[3,4], but also by their ecto-ADPase activity[5], which initiates the conversion of pro-aggregating ADP to adenosine, a potent vasodilator[6] and platelet inhibitor[7]. We have now demonstrated that cultured aortic endothelial cells exposed to trypsin, thrombin or other stimuli can liberate a high proportion of their adenine nucleotides without substantial loss of lactate dehydrogenase. ADP rapidly accumulates extracellularly, reaching biologically active concentrations before there is further breakdown to adenosine. Whether this selective release of nucleotides is a response to damage, or whether it represents a specific secretory mechanism remains to be resolved. Cultured aortic smooth muscle cells can secrete adenine nucleotides in a similar manner, but extracellular conversion to adenosine occurs much faster.

The production of PGI_2 has previously been demonstrated by the ability of cultured vascular cells to inhibit platelet aggregation induced by a variety of stimuli[1,2,8–10]. Using porcine aortic

0028–0836/79/400384—03$01.00

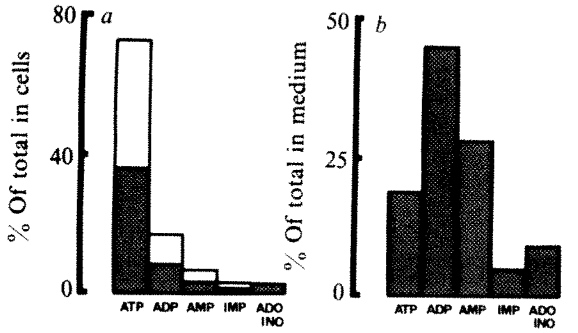

Fig. 1 Adenine nucleotides of cultured porcine aortic endothelial cells were labelled by incubating replicate confluent monolayers in 16-mm diameter wells ($\approx 10^5$ cells per sample) for 60 min with 2 μM ^{3}H-adenosine[11]. The cells were rapidly rinsed three times, then samples were treated with 0.1% trypsin plus 0.025% EDTA in PBS at 37 °C for 5 min, and the supernatant was separated from suspended cells by rapid centrifugation. Purines extracted from the cells before or after treatment with trypsin plus EDTA, or in the supernatant after treatment, were separated by thin layer chromatography and the radioactivity in each fraction was determined[11]. Radioactivity associated with inosine was usually only ~5% of the total, and adenosine and inosine have been combined here (ADO, adenosine; INO, inosine). In *a*, the total height of each column represents the percentage of the total radioactivity incorporated by the cells into each compound. The shaded portion of each column represents the percentage (again of the original radioactivity) in each compound after treatment with trypsin plus EDTA. Thus, the unshaded portion of each column shows the labelled compounds lost from the cells. *b* Shows the distribution of extracellular radioactivity, expressed as percentage of the total release.

endothelial cells in culture[11], we showed that PGI$_2$ production was blocked by low concentrations of aspirin[12], and during further experiments with aspirin-treated cells we found that they could aggregate platelets directly when cell suspensions were prepared from monolayer cultures by a conventional procedure: treatment with 0.1% trypsin plus 0.025% EDTA for 5 min at 37 °C followed by the addition of 0.1 volume of serum to inactivate the trypsin. This aggregation was inhibited by 1–10 μM 2-azido-AMP, which is an antagonist of the ADP receptor on platelets[13], and when cell-free supernatants were prepared by centrifuging, these contained a stable pro-aggregatory compound whose action was similarly blocked by 2-azido-AMP. The aggregation response was almost abolished when the supernatant was incubated for 50 min with 100 μg ml^{-1} apyrase (Sigma, grade I). Treatment with 10 μg ml^{-1} apyrase resulted in the response being initially potentiated (>200% of the control after 15 min) then reduced after longer incubation. This suggested that ATP and ADP were released from the endothelial cells by the procedure used to detach them; the ATPase activity of the apyrase was three to five times its ADPase activity (according to Sigma), and the results were therefore consistent with an initial conversion of ATP by apyrase and slower degradation of the ADP thus formed, together with that originally present.

To investigate the release of nucleotides in more detail, we took advantage of the fact that endothelial cells have a high-affinity transport process for adenosine through which ^{3}H-adenosine is predominantly incorporated into ATP and ADP within the cells[11]. Cell suspensions were prepared from prelabelled monolayers by treatment with trypsin and EDTA as above; the cells were then separated from the extracellular medium by centrifuging, and the cellular and extracellular amounts and distribution of ^{3}H measured by thin layer chromatography and liquid scintillation counting[11]. The fraction of the total cellular radioactivity released varied in different experiments (usually 10–30%, occasionally >50%) but the pattern of ^{3}H release was highly consistent. In all experiments the main component lost from the cells was ^{3}H-ATP (Fig. 1*a*), but the largest fraction appearing extracellularly was ^{3}H-ADP (Fig. 1*b*). Release of up to 60% of the intracellular ^{3}H, in a similar pattern, also occurred when cells were suspended by physical disturbance with a rubber policeman. To check that the radioactivity released did not represent a small pool of preferentially labelled nucleotides, we measured the total ATP content of cells and extracellular medium using luciferase[14]. The total cellular ATP concentration was ~4 nmol per 10^6 cells, of which up to 50% was released when cell suspensions were prepared using trypsin plus EDTA as described above.

The high fraction of cellular nucleotides released when the cells were suspended with trypsin plus EDTA was not accompanied by any evidence of cell damage as measured by vital dye exclusion (no detectable staining of cells with trypan blue) or cytoplasmic enzyme leakage (extracellular lactate dehydrogenase activity was <5% of the total cellular activity). Thus, the cells could liberate up to half their adenine nucleotides without the plasma membrane becoming significantly permeable to compounds of higher molecular weight. This selective release of nucleotides was not simply a consequence of the cells becoming detached from their substratum: there was always a small but significant release of nucleotides from prelabelled cells on replacing the medium above the monolayer with fresh medium, and this release was increased by adding agents such as collagenase or thrombin that did not detach the cell monolayer. For example, the addition of fresh culture medium alone at 37 °C for 5 min induced 7.2 ± 1.4% release of incorporated ^{3}H; medium containing 0.2% collagenase released 14.0 ± 0.7% (mean ± s.d., $n = 4$). Treatment with 1–5 U ml^{-1} thrombin for 5 min at 37 °C released up to 25% of ^{3}H without visibly affecting cell morphology. The pattern of extracellular nucleotides found in these experiments was very similar to that obtained using trypsin plus EDTA. Nucleotide release was temperature dependent; for example, the addition of phosphate-buffered saline (PBS) alone for 5 min at 37 °C released 5.3 ± 0.7% whereas at 4 °C release was 2.3 ± 0.7% (mean ± s.d., $n = 4$). Release was not reduced when cells were treated with trypsin and EDTA in PBS containing 10 mM ATP (test release 26.5 ± 3.0%; release in the absence of ATP 24.3 ± 4.8% (mean ± s.d., $n = 4$)). Also, there was no uptake of labelled exogenous nucleotide in conditions inducing selective release of intracellular nucleotides: when PBS containing 1 μM–4 mM ^{3}H-ATP (~2×10^6 d.p.m.) plus 10–100 μM dipyridamole was added to an endothelial monolayer for 5 min at 37 °C, the presence of trypsin plus EDTA did not result in any significant increase in the radioactivity associated with the cells (for example, 0.15% in control, 0.14% with trypsin plus EDTA, means of three observations). Dipyridamole, a potent inhibitor of adenosine uptake by endothelial cells[11], was added to prevent uptake of any ^{3}H-adenosine formed during the incubation with ^{3}H-ATP,

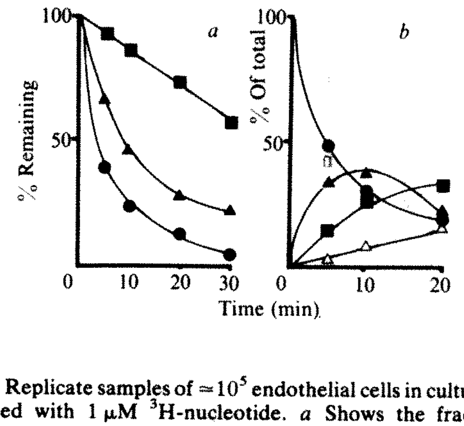

Fig. 2 Replicate samples of $\approx 10^5$ endothelial cells in culture were incubated with 1 μM ^{3}H-nucleotide. *a* Shows the fraction of substrate in serum-free HEPES-buffered Dulbecco's medium[23] remaining unchanged outside the cells at various times after incubation. *b* Shows the pattern of metabolites outside cells incubated with ATP in PBS containing 1.8 mM Ca^{2+}. ●, ATP; ▲, ADP; ■, AMP; △, adenosine. Dipyridamole (10 μM) was present in all experiments.

because we had confirmed (see below) the recent report[15] that endothelial cells could metabolise extracellular ATP to adenosine.

It was clear that nucleotide metabolism occurred either during or after release, because the pattern of intracellular nucleotides secreted was (as shown in Fig. 1) different from that found outside the cells. This difference was even more striking when similar experiments were carried out using cultured pig aortic smooth muscle cells: up to 50% of the ^{3}H secreted by smooth muscle cells was detectable after 5 min as ^{3}H-adenosine, although again the main intracellular change was a loss of ^{3}H-ATP. We did, however, establish that at shorter time intervals most of the label released was ATP. To investigate the extent of extracellular metabolism of adenine nucleotides in more detail, cultures of endothelial cells or smooth muscle cells were incubated with individual labelled nucleotides and the metabolites in the culture medium determined.

Figure 2*a* shows that endothelial cells catabolised added ATP, ADP or AMP and the half lives were, respectively, <5, ≈ 10 and >30 min at 1 μM substrate concentration. With smooth muscle cells the half life for each nucleotide was ≈ 5 min in the same conditions. Metabolism of added ^{3}H-ATP by endothelial cells resulted in an initial transient peak of ^{3}H-ADP, followed by a more prolonged peak of ^{3}H-AMP and finally a progressive increase in ^{3}H-adenosine (Fig. 2*b*). When the same experiment was carried out using smooth muscle cells, the peaks of ^{3}H-ADP and ^{3}H-AMP were much smaller and never exceeded the amount of adenosine formed.

Taken together, these results suggest sequential degradation of extracellular nucleotides (ATP → ADP → AMP → adenosine) by both endothelial cells and smooth muscle cells, although the relative rates of breakdown differ significantly in the two cell types. The pattern of extracellular nucleotides found after 5 min trypsinisation of each cell type is consistent with the transient release of ATP, and a smaller amount of ADP, followed by extracellular metabolism.

Our findings raise an important caveat for experiments with platelets and cultured cells. We, and others, have previously used a platelet aggregation bioassay to estimate the production of PGI_2 by cultured vascular cells, in which the cells are usually suspended by conventional procedures similar to those described in the present study—the use of trypsin, collagenase, EDTA or a rubber policeman[1,2,8–10]. As we have now demonstrated a hitherto unsuspected selective release of adenine nucleotides from cultured vascular cells, affecting platelet aggregation, this must be considered in future experiments using this method.

The selective release of ATP from cultured endothelium seems to be a cellular response to potentially damaging stimuli. It is not a nonspecific increase in membrane permeability like that associated with cell lysis, because the cells remain viable and there is very little release of cytoplasmic protein. Nor is it apparently a secretory process involving degranulation—we found no evidence for compartmentalisation of endothelial ATP. We also failed to demonstrate any inward transport of ATP across the endothelial plasma membrane; this implies that the selective release may represent a unidirectional increase in membrane permeability to nucleotides. The release process could be in some respects analogous to the selective release of prostaglandins from stimulated cells, but the precise mechanism involved remains to be determined.

Whatever the mechanism responsible, the release of nucleotides from vascular endothelium *in vivo* would have great biological significance, because adenine nucleotides and adenosine not only influence platelet aggregation but are also potent vasoactive agents. Efflux of adenosine, with smaller quantities of nucleotides, has been measured in several perfused vascular preparations[16–18], particularly in the vasculature of cardiac or skeletal muscle during hypoxia, where the circulating adenosine is thought to act as a local hormone to increase blood flow[19–21]. Although adenosine itself might be released from endothelium or muscle cells, perhaps by the uptake process operating in reverse, this seems unlikely, as the intracellular concentration of adenosine is very low ($<1\%$ of the ATP concentration), and the reactive hyperaemia caused by endogenous adenosine during hypoxia is potentiated by inhibitors of adenosine transport such as dipyridamole[22]. An alternative pathway would be the selective release of a small proportion of the cells' ATP with subsequent conversion to adenosine by the ectoenzymatic cascade. Further work is needed to test whether this pathway, which we have observed *in vitro*, operates *in vivo* (for example, in response to hypoxia) to regulate vascular tone.

2-Azido-AMP was provided by Dr N. J. Cusack.

Orthotopic bone induction at sites of Moloney murine sarcoma virus inoculation in mice

K. Wlodarski

Department of Histology and Embryology,

M. Kobus & M. Luczak

Department of Virology, Institute of Biostructure, Medical School, Warsaw, Poland

Moloney murine sarcoma virus (M-MSV) induces at the site of inoculation in newborn[1,2] and adult[3–5] mice and rats various types of sarcoma[1,6], including osteosarcoma[7,8]. The induced tumours are fatal in newborn mice[3,9], whereas sarcomas developed in adult animals regress spontaneously[3,5,10–12]. The regression is mediated mainly by a cellular response[3,5,10–12]. We have now demonstrated that the presence of sarcomas induced by M-MSV is a powerful stimulus for periosteal osteogenesis around tumour masses. Orthotopically induced osteogenesis by M-MSV may serve as a model for local regulation of bone growth and for cell differentiation studies, and may help explain the aetiology of some human bone disorders.

Inbred 5-week-old NMRI mice of both sexes were inoculated into left shanks with 0.2 ml of standard M-MSV diluted 1 : 5 in phosphate-buffered saline. The virus was prepared according to Chanaille *et al.*[13] (10^3 TID_{50} in 0.2 ml). Mice were killed at various intervals between the 3rd and 190th days after inoculation and both shanks, one inoculated with M-MSV and the intact contralateral control, were fixed in Susa solution. Paraffin

0028–0836/79/400386—02$01.00

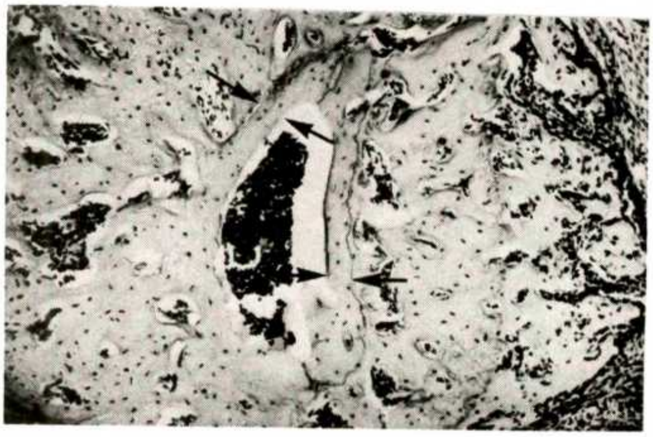

Fig. 1 Periosteal cancellous bone formation in ulna, 16 days after M-MSV inoculation. Arrows indicate the original width of the ulna cortex. ×60.

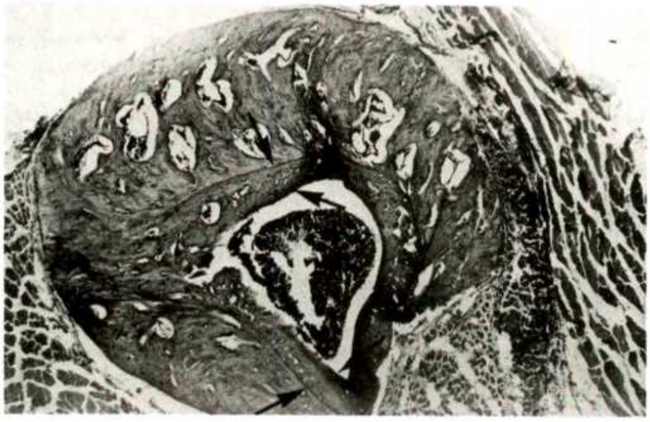

Fig. 2 Tibia, 2 months after M-MSV inoculation and 1 month after tumour regression. Arrows indicate the original width of the tibia cortex. ×38.

sections from the middle of the shanks were cut perpendicularly to the tibial axis, and stained with haematoxylin and eosin. As an additional control five mice were inoculated with heat-inactivated M-MSV (heated at 56 °C for 2 h).

Of 36 mice inoculated with active M-MSV, 34 developed tumours (95%). Tumours grew progressively up to days 14–16, then declined and disappeared completely by days 25–32. Tumours were pleomorphic and had large elongated and round cells with a single hypertrophic nucleus and distinct nucleoli, small fibrosarcoma-like cells predominated. Neoplastic cells were infiltrated with numerous neutrophils. A massive destruction of muscles was always observed during the progressive phase of tumour growth. The regression of tumours was associated with regeneration of muscles, the disappearance of neoplastic cells, and the accumulation of macrophages, fibroblasts and lymphocytes. No heterotopic osteogenesis was observed either during progressive tumour growth or during regression.

A virus-induced sarcoma acts as a very powerful stimulus for orthotopic periosteal osteogenesis. In all cases the presence of tumours was associated with new bone formation in the periosteum of the tibia and/or ulna. In control bones the periosteum was composed of two to four layers of fibroblasts. At 6 days after M-MSV inoculation the periosteum became a thick membrane, composed of 7–20 layers of osteoblasts and fibroblasts; mitotic forms were frequent and osteoid deposition had begun. Bone formation continued until day 16. By this time the newly formed cancellous bone covering the old original cortex was three to five times thicker than the original bone (Fig. 1). The orthotopic bone formation was uneven, sometimes affecting the whole periphery, but always taking place on sites which faced the tumorous tissue. Newly formed orthotopic bone ossicles were also sites of myelopoiesis. Bone formation ceased with tumour regression. During tumour regression the remodelling processes converted induced trabecular bone into more mature forms. Orthotopically induced bone also stopped growing and became covered with periosteal membrane of normal histology (Fig. 2).

Tumours did not form in shanks inoculated with heat-inactivated M-MSV, and there was no periosteal stimulation or bone formation. In the two mice in which inoculation of active M-MSV did not produce tumours, no changes in bone and periosteum histology were observed.

Orthotopically induced bone persisted throughout the 6-month observation period, remained unresorbed, and did not exhibit neoplastic changes. The results obtained may explain some aspects of the aetiology of osseous deformation, such as exostoses. It is not clear whether proliferation of the periosteum is caused by the virus itself, or whether it is mediated by tumour and/or inflammatory cells. M-MSV does not induce osteosarcomas when administered intramuscularly, but when administered into the medullar cavity of newborn rat tibia the virus induces highly malignant osteosarcomas[8]. The development of tumours precedes the stimulation of the periosteum, however, which suggests a direct mechanism of periosteal stimulation.

Growth of a human mammary tumour cell line in a serum-free medium

David Barnes & Gordon Sato

Department of Biology, Q-058, University of California, San Diego,
La Jolla, California 92093

The MCF-7 line of human mammary carcinoma cells is a well characterised line[1] which has retained a number of the properties expressed by breast epithelium *in vivo*, making it a good model for the *in vitro* study of normal and neoplastic mammary cells. MCF-7 cells have been reported to possess receptors for oestrogen, androgen, progesterone, glucocorticoid[2], insulin[3] and L-3, 3′, 5-triiodothyronine (T$_3$)[4]. These cells also show responses to prolactin[5], and dome formation[1]. This line, like most cells in culture, requires the addition of a serum supplement to the medium for growth. The complex and undefined nature of serum adds a complicating aspect to the design and interpretation of any experiments aimed at understanding the interactions of hormones or drugs with mammary epithelium. Our laboratory has shown that it is possible to replace the serum requirement for a number of cell lines with mixtures of hormones and purified serum factors[6–8]. We now report that MCF-7 cells may be grown, without a lag or adaptation phase, in a serum-free medium supplemented with physiological levels of insulin, transferrin, epidermal growth factor (EGF), prostaglandin F$_{2\alpha}$ (PGF$_{2\alpha}$) and cold-insoluble globulin (CIg). This medium will support a growth rate identical to that of cells in medium supplemented with an optimal concentration of fetal calf serum. The further addition of the α-1 serum protein first purified by Holmes[9] results in a morphology identical to that of cells in 10% serum. Turkington has previously shown EGF effects on mouse mammary explant cultures[10], and mouse EGF has been reported to be stimulatory for human mammary tumour cells[11]. Insulin and transferrin have been shown to be required for the continuous serum-free growth of the ZR-75-1 human mammary tumour cell line[12]. We believe that this is the first report of the effects of transferrin, PGF$_{2\alpha}$, CIg, EGF or the α-1 protein on the MCF-7 line.

Figure 1 shows the growth over an 8-d period of MCF-7 cells in medium supplemented with 10% fetal calf serum or with the five factors. The doubling time in both conditions was about 36 h. This generation time agrees with that reported by other laboratories for these cells[13]. Addition of the five factors to cells in medium with 10% fetal calf serum did not increase cell number beyond that seen with 10% serum alone (data not shown). In serum-free medium in the absence of the five factors cell death occurred after 4 d. Cell growth in the serum-free medium began to slow 6 d after plating and fell behind that of serum by day 8. In most experiments cell number in serum-supplemented medium at any point in the growth curve was higher than that of cells in the serum-free medium. This reflected a higher initial plating efficiency in serum-supplemented medium compared with serum-free medium, but did not represent a significantly lower doubling time in the serum-free medium. The synthetic nutrient medium used in these experiments was a 1:1 mixture of Ham's F12 and Dulbecco-modified Eagle's medium (DMEM) supplemented with antibiotics, 1.2 g l^{-1} sodium bicarbonate, 15 mM HEPES, *p*H 7.4, and 10^{-8} M sodium selenite. No growth was seen in DMEM supplemented with the five factors, and growth in F12 supplemented with the five factors was 80% of that seen in the mixture of the two.

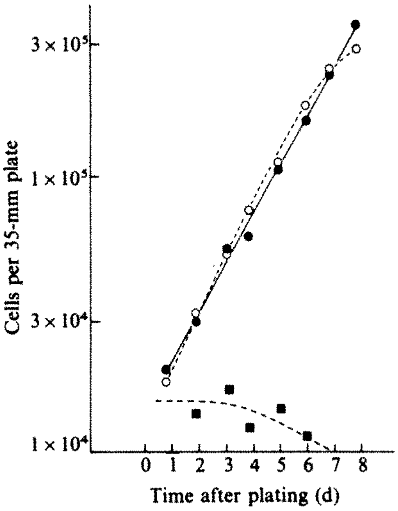

Fig. 1 Growth of MCF-7 cells in serum-free medium. Stock cultures for experiments were grown in a one to one mixture of F12 and DMEM supplemented with antibiotics, 15 mM HEPES *p*H 7.4, 1.2 g l^{-1} sodium bicarbonate and 10% fetal calf serum (Reheis). Cells were detached from stock flasks with a trypsin-EDTA solution in phosphate-buffered saline, treated with trypsin inhibitor, and plated at 3×10^4 cells per 35-mm diameter plate in 2 ml medium supplemented with 250 ng ml^{-1} insulin (Sigma), 25 μg ml^{-1} transferrin (Sigma), 100 ng ml^{-1} EGF (Collaborative Research), 100 ng ml^{-1} PGF$_{2\alpha}$ (Sigma) and 7.5 μg ml^{-1} CIg (Collaborative Research) (○). Control plates contained medium with 10% fetal calf serum (●), or medium with no stimulatory supplements (■). Data shown are the average of triplicate samples. Deviation of single samples from the average was about 5%. For counting, cells were treated with trypsin-EDTA, sheared through a 22-gauge hypodermic needle to produce a single cell suspension, and counted in a Coulter counter. Cell suspensions treated in this way gave counts identical to those counted with a haemocytometer.

Table 1 Effect of insulin, transferrin, PGF$_{2\alpha}$, EGF and CIg on growth of MCF-7 cells in serum-free medium

Conditions	Cells per 35-mm plate ($\times 10^{-4}$)
No additions	4.4 ± 0.1
Insulin, transferrin, EGF, PGF$_{2\alpha}$, CIg	35.0 ± 0.9
Insulin omitted	11.4 ± 1.4
Transferrin omitted	28.4 ± 2.3
PGF$_{2\alpha}$ omitted	30.4 ± 2.0
CIg omitted	27.7 ± 1.0
EGF omitted	34.6 ± 2.4
10% fetal calf serum	40.0 ± 2.8

Cells were plated at 3×10^4 per 35-mm diameter plate in medium with the indicated additions. Concentrations of the factors were the same as that of Fig. 1. Cells were counted 7 d after plating. After 14 d (medium changed on day 8), cell number in medium with the five factors was 85.1×10^4 per plate. In medium with EGF omitted cell number was 78.8×10^4 per plate.

The individual omission of either insulin, transferrin, PGF$_{2\alpha}$, or CIg from the medium resulted in decreased cell number after 7 d (Table 1). Longer incubations (10–14 d) were required to demonstrate EGF effects. EGF effects could not be observed at earlier times if insulin was omitted or the insulin concentration lowered. Insulin was clearly the most important component of the defined medium. In dose–response studies carried out in the presence of the other factors, the maximal effect of insulin was observed with 100–300 ng ml^{-1} with an easily measurable effect at 3 ng ml^{-1}. Transferrin produced a maximal stimulation at 25 μg ml^{-1} with a measurable effect at 1 μg ml^{-1}. The CIg effect was maximal at 7.5 μg ml^{-1} with a measurable effect at 0.75 μg ml^{-1}. CIg at these concentrations is also stimulatory for the RF-1 rat ovary cell line[14] and a mouse embryonal carcinoma line[15]. The effect of CIg on cell number in Table 1 was not due to decreased shedding of cells into the medium. The number of cells floating in the medium was less than 2% of the total number in the dish and this percentage was unchanged by omission of CIg from the medium. The transferrin concentration used in the

0028–0836/79/400388—02$01.00

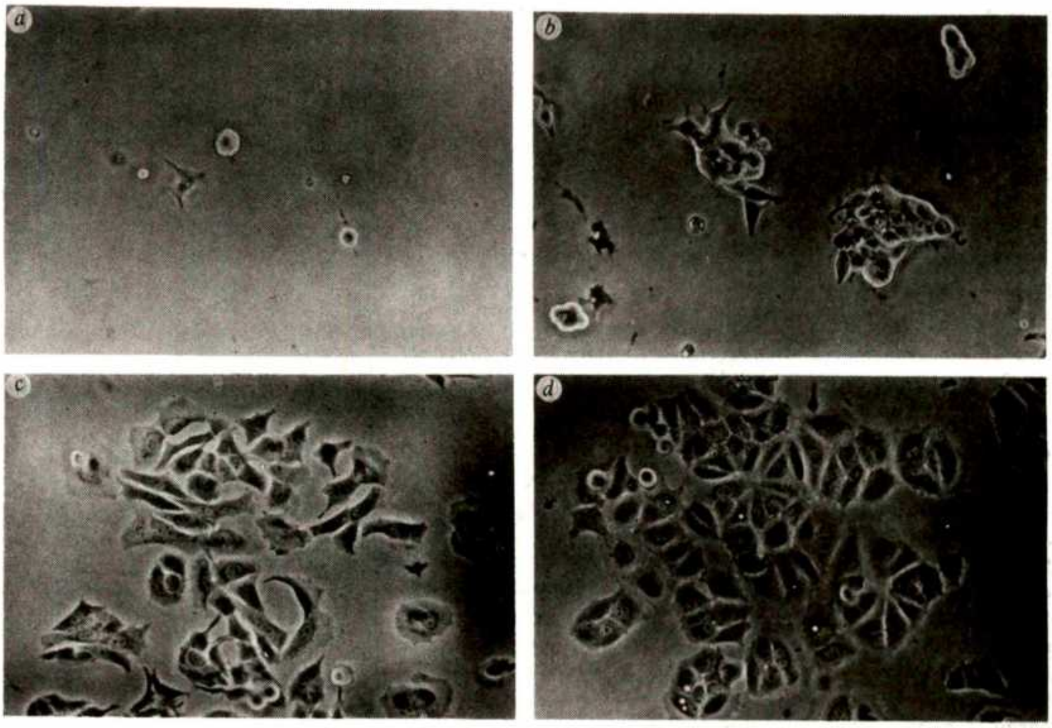

Fig. 2 Effect of the α-1 protein of Holmes on morphology of MCF-7 cells in serum-free medium. Cells were incubated for 3 d in (*a*) medium with no stimulatory supplements, (*b*) medium with the five factors as described in Fig. 1, (*c*) medium with five factors plus the α-1 protein (GIBCO), and (*d*) medium with 10% fetal calf serum. The human α-1 protein was used at a dilution of 1:10. Protein concentration of the α-1 protein in the medium, calculated from information provided by the vendor, was about 250 ng ml^{-1}.

serum-free medium (25 μg ml^{-1}) is about 1/10th (ref. 16), and the CIg concentration (7.5 μg/ml^{-1}) about one-third[17], that which would be found in medium containing 10% serum. PGF$_{2\alpha}$ was maximally stimulatory at 100 ng ml^{-1} and EGF at 10–100 ng ml^{-1}. Both of these factors showed some stimulation at 1 ng ml^{-1}. No increase in cell number was seen on addition of physiological levels of other hormones which have effects on mammary epithelia, including human prolactin, porcine relaxin and vasopressin.

Cells in serum-free medium with the five factors grew as rounded clumps which were poorly attached to the dish, or groups of cells which were attached but poorly spread. The addition of the α-1 serum protein, which has been reported to enhance the growth and spreading of HeLa cells[9], resulted in a striking change in morphology (Fig. 2). This protein greatly improved attachment and spreading of MCF-7 in serum-free medium at concentrations of 1 μg ml^{-1} or less.

Increased cell number has been reported for MCF-7 under various circumstances upon addition of insulin[18], oestrogen[19], androgen[20] or T$_3$ (ref. 4). The androgen effect is reported to be mediated by the oestrogen receptor[21]. Morphological effects of both T$_3$ and oestradiol at concentrations as low as 10^{-10} M were observed in our medium containing the five factors, but no increase in cell number was seen after incubations as long as 14 d, with a medium change on day 7. However, additions of oestradiol at 10^{-9} M did result in an increase in cell number if the oestrogen was added to cells plated in the α-1 serum protein alone (W. Desmond, D. B. and G. S. in preparation). Although it is possible that long-term cultivation of MCF-7 cells in our serum-free medium may expose additional requirements for other hormones, these cells have so far been successfully carried for over 3 months (15 passages) in the serum-free medium.

If great care is taken on transfer to insure removal of residual trypsin, proper control of medium *p*H and temperature and to minimise the amount of time they are out of the incubator, the cells may be continually passaged in the serum-free medium without loss of viability or lengthening of generation time. When cells were grown for five passages in the serum-free medium and then plated in medium with 10% fetal calf serum or medium with the five factors, cell number after 6 d in plates with medium with the five factors was 80% of the cell number in plates with 10% serum.

Allegra and Lippman[12] have described a serum-free medium for ZR-75-1 human mammary tumour cells which includes insulin, transferrin, dexamethasone, T$_3$ and oestradiol. This medium will not support the growth of MCF-7. Although it is not known if the ZR-75-1 line will grow in the medium devised for MCF-7, preliminary experiments indicate that, in addition to MCF-7, another human mammary carcinoma cell line, BT20, also grew in serum-free medium supplemented with insulin, transferrin, EGF, PGF$_2\alpha$, CIg, and the α-1 protein.

A serum-free medium for MCF-7 cells should be useful for several reasons. This medium will greatly facilitate pharmacological and nutritional studies of MCF-7. Studies of hormone binding and subsequent biological effects may now be carried out on healthy, growing, non-selected cells in the absence of interfering hormones or serum proteins. Serum-free medium will allow the easy identification and isolation of products synthesised and secreted by the cells into the medium. Finally, a serum-free medium for human mammary tumour cells may allow the isolation of new lines of normal or neoplastic human mammary epithelium in the absence of other contaminating cell types.

We thank Dr C. McGrath and Dr W. McGuire for gifts of MCF-7 cells. Experiments described were carried out with MCF-7 cells supplied by Dr McGuire. MCF-7 cells provided by Dr McGrath also grew in the serum-free medium. We also thank Dr D. McClure, Dr W. Desmond and Dr G. Rockwell for critical reading of the manuscript and many helpful discussions of the data. This work was supported by a NCI postdoctoral grant IF32CA06188-01 and a NCI contract N01-CB74188.

Platelet-derived growth factor prevents G_0 growth arrest

Baserga[1] has summarised evidence that there are two growth states in which cells have a diploid content of DNA; G_1—the interval between mitosis and S phase in exponentially growing cultures—and G_0, a quiescent state entered only when conditions for growth are suboptimal. G_0 can be distinguished from G_1 by temporal measurements; for BALB/c 3T3 cells, the lag time between G_0 and S phase is never shorter than 12 h (ref. 2), whereas in exponentially growing cells the mean lag time between mitosis and S (G_1 by definition) lasts 5–6 h (ref. 3). G_0 can also be distinguished from G_1 by some biochemical parameters including G_0- and G_1-specific intracellular proteins[4,5]. SV40- or polyoma virus-transformed cells cannot enter G_0 to become quiescent[6–9]. Serum induces the growth of BALB/c 3T3 cells in tissue culture. It sustains the growth of exponentially replicating populations, and causes density-inhibited cells to leave G_0 and replicate[10–12]. Serum contains several sets of hormonal growth factors which have recently been defined[2,13,14]. One of these hormones, the platelet-derived growth factor (PDGF), is released into serum during the clotting process; PDGF is absent in platelet-poor plasma, the liquid portion of unclotted blood[15–19]. It promotes the growth of G_0-arrested cells[2,16] by stimulating cells to become 'competent' to enter the S phase[2]; plasma allows these competent cells to progress through G_0/G_1, synthesise DNA[2,20] and divide[13]. We now show that PDGF has a second function. It prevents replicating cells from entering G_0.

Density-inhibited cultures of BALB/c 3T3 cells (clone A31) were treated for 5 h with platelet extract containing partially purified PDGF to induce the majority of the cells to become competent for replication. Transfer of these cells to medium containing an optimal concentration (5%) of dialysed platelet-poor plasma allows these cells to begin to enter the S phase after a lag of 12 h (refs 2, 20, 21). Addition of the dihydrofolate reductase inhibitor methotrexate[22] (100 nM) prevented DNA synthesis, and flow microfluorimetry demonstrated that the growth-arrested cells had an apparent G_1 content of DNA (data not shown). The methotrexate was removed and plasma-supplemented medium containing hypoxanthine and thymidine was added; duplicate cultures were treated with ^{3}H-thymidine (TdR) or colchicine for 1 h, at various times after removal of the methotrexate, and fixed[2]. DNA synthesis, as determined by autoradiography, was detected in 87% of the cells within the first hour after removal of the methotrexate (Fig. 1). The percentage of cells synthesising DNA remained constant for 6 h and then fell abruptly. By 10 h, little DNA synthesis was detected, indicating that the S phase had been completed. Mitosis was somewhat less synchronous, beginning at 9 h, reaching a peak at 11 and ending by 15 h. Treatment of cells with PDGF after the removal of methotrexate did not alter the kinetics of DNA synthesis or mitosis (data not shown).

Cells arrested by plasma withdrawal shortly before the onset of DNA synthesis enter the S phase with first-order kinetics, whereas cells blocked in early S phase begin DNA synthesis in a synchronous fashion[20,23]. Thus, the data indicate that methotrexate blocks cells near the G_1/S phase boundary in early S phase.

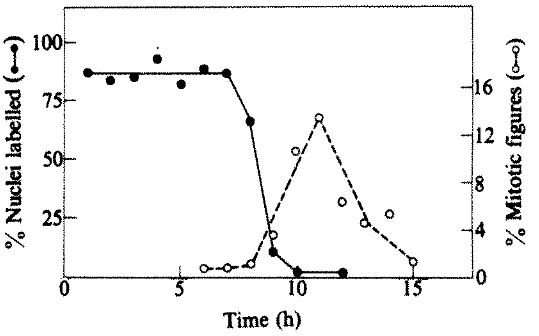

Fig. 1 Methotrexate causes growth arrest in early S phase. BALB/c 3T3 cells (clone A31) were grown to confluence on Falcon microtitre wells (area 0.3 cm^2) in Dulbecco's modified Eagle's medium containing 10% calf serum[2]. Density-inhibited cultures were treated with 150 μg ml^{-1} of heat (100 °C)-treated platelet extract containing PDGF for 5 h, washed once and transferred to medium containing 5% (v/v) dialysed human plasma containing 100 nM methotrexate (National Cancer Institute). After 18 h all cultures were transferred to fresh medium containing 5% plasma, 106 nM hypoxanthine and 16 nM thymidine. ^{3}H-TdR (5 μCi ml^{-1}) was added to duplicate cultures at hourly intervals after removal of the methotrexate. The cells were fixed 1 h after addition of ^{3}H-TdR at the time shown, washed twice with 5% trichloroacetic acid and processed for autoradiography. Duplicate cultures were treated with 2 μM colchicine (GIBCO) for 1 h and fixed at the time shown; the percentage of mitotic figures was determined.

Density-inhibited BALB/c 3T3 cells were treated first with platelet extract containing PDGF and then with 5% plasma containing methotrexate as above; 18 h later, when 90% of the cells were growth arrested in early S phase, the methotrexate block was removed. ^{3}H-TdR was added to the cultures 16 h after removal of the methotrexate to study DNA synthesis in the post-mitotic daughter cells. Without further PDGF treatment, <10% of the daughter cells entered the S phase within the 27 h period after removal of the methotrexate block (Table 1). Addition of partially purified PDGF to the parent cells for 2-h periods during the first 8 h after removal of the methotrexate (corresponding largely to parental cell S and G_2) induced 60–70% of the daughter cells to synthesise DNA (Table 1). The

Table 1 Treatment with PDGF during the S phase stimulates post-mitotic daughter cells to synthesise DNA

Interval (h) treated with PDGF after methotrexate removal	% Of daughter cells synthesising DNA
0–2	67
2–4	68
4–6	70
6–8	59
Untreated	9

Density-inhibited BALB/c 3T3 cells were treated with 150 μg ml^{-1} of heat-treated platelet extract containing PDGF for 5 h, washed once[2] and transferred to medium containing 5% (v/v) dialysed human plasma containing 106 nM methotrexate. After 18 h all cultures were transferred to fresh medium containing 5% plasma, 100 nM hypoxanthine and 16 nM thymidine. Addition of ^{3}H-TdR (5 μCi ml^{-1}, final concentration 0.3 Ci mmol^{-1}) from 0–2 h after the methotrexate was removed, followed by immediate fixation and autoradiography, demonstrated that 90% of the parent cells synthesised DNA. Duplicate cultures were treated with heat-treated platelet extract (150 μg ml^{-1}) in the presence of hypoxanthine and thymidine, but in the absence of plasma for the interval shown (or were left untreated), washed twice with medium and returned to the plasma-supplemented medium containing hypoxanthine and thymidine. Approximately 16 h after the methotrexate was removed, ^{3}H-TdR was added; the cultures were fixed and processed for autoradiography 11 h later and the percentage of post-mitotic daughter cells entering the S phase was determined.

0028-0836/79/400390—03$01.00

percentage of PDGF-treated daughter cells that entered the S phase was also controlled by the concentration of plasma in the medium; in 0.25% plasma 30% of the daughter cells entered the S phase, compared with 90% in 5% plasma.

To study the effect of the PDGF concentration on the percentage of post-mitotic daughter cells stimulated to enter the S phase, platelet extract was briefly added to parental cells undergoing DNA synthesis. The percentage of daughter cells stimulated to synthesise DNA increased approximately linearly as a function of the logarithm of the platelet extract concentration over a 10-fold range (Fig. 2*a*). Treatment of parent cells with pure PDGF[19] also stimulated the daughter cells to synthesise DNA in a dose-dependent fashion (Fig. 2*b*). A 2-h treatment with 5 ng ml^{-1} of a homogeneous preparation of PDGF stimulated 50% of the daughter cells to enter the S phase.

To study the lag phase until DNA synthesis in post-mitotic daughter cells, duplicate cultures were released from the methotrexate block and briefly treated with partially purified PDGF. Treatment of the parent cells with PDGF from 0–2 or 4–6 h after release of the methotrexate block (corresponding to early or middle S phase) induced the daughter cells to begin synthesising DNA 15 h from the release of the methotrexate block (Fig. 3*a*, *b*), approximately 6 h after the beginning of mitosis. Addition of PDGF from 8–10 h after methotrexate removal (corresponding largely to parental G_2 and M phases) stimulated the daughter cells to enter the S phase at 17 h, approximately 7 h after the PDGF treatment was completed and the cells were returned to plasma (Fig. 3*c*). Addition of PDGF to the post-mitotic daughter cells, 12–14 h after the methotrexate was removed largely corresponding to G_1, 3–5 h after the beginning of mitosis, induced the cells to enter the S phase 7 h after the PDGF treatment (Fig. 3*d*). However, addition of the PDGF to the post-mitotic daughter cells 16–18 h after methotrexate was removed (7–9 h after the beginning of mitosis) resulted in a significant delay in S phase entry (Fig. 3*e*). These cells began to enter the S phase 12 h after PDGF was removed, demonstrating that they had become arrested in the G_0 phase of the cell cycle.

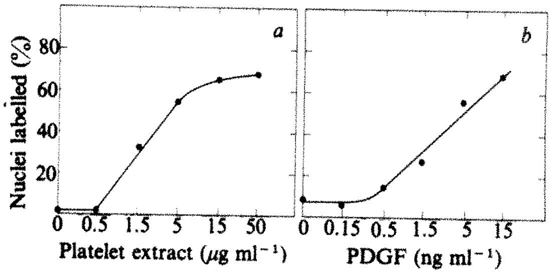

Fig. 2 The concentration of PDGF regulates the percentage of post-mitotic daughter cells synthesising DNA. Density-inhibited BALB/c 3T3 cells were treated with partially purified PDGF and transferred to 5% plasma-supplemented medium containing methotrexate as outlined in Fig. 1 legend. After 18 h the medium was removed from all cultures; some cultures were transferred to medium containing 5% plasma, hypoxanthine and ^{3}H-TdR (5 μCi ml^{-1}; 0.3 Ci mmol^{-1}) and fixed 8 h later. Autoradiography demonstrated that 90% of the PDGF-stimulated cells and <1% of the unstimulated cells entered the S phase. Duplicate cultures were treated with heat-treated platelet extract (*a*), or pure PDGF which was purified to homogeneity from clinically outdated human platelets as has been described elsewhere[19] (*b*), at the concentrations shown, plus thymidine and hypoxanthine. Two hours later the PDGF source was removed, the cultures were washed and transferred to 5% plasma-supplemented medium containing hypoxanthine and thymidine. ^{3}H-TdR was added to the cultures 10 h after removal of the platelet extracts. The cultures were fixed and processed for autoradiography 16 h later. The lag phase for DNA synthesis is 12 h after plasma addition for the G_0-arrested cultures[2], and 13 h for the second wave of DNA synthesis (Fig. 3*a*) in the S phase cultures.

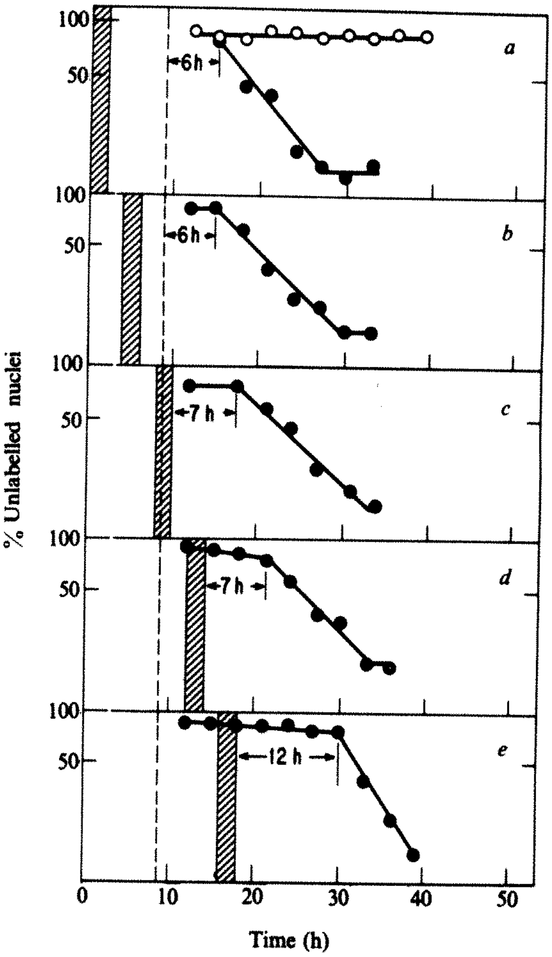

Fig. 3 Treatment with PDGF during S, G_2 or M phases, or immediately after mitosis, prevents replicating BALB/c 3T3 cells from becoming growth arrested at G_0. Density inhibited BALB/c 3T3 cells were treated with partially purified PDGF and transferred to 5% plasma-supplemented medium containing methotrexate as outlined in Fig. 1 legend. After 18 h, the medium was removed from all cultures; some cultures were transferred to medium containing 5% plasma, hypoxanthine and ^{3}H-TdR (5 μCi ml^{-1}; 0.3 Ci mmol^{-1}) and fixed 8 h later. Autoradiography demonstrated that 91% of the PDGF-stimulated parent cells entered the S phase. Duplicate cultures were transferred to 5% platelet-poor plasma containing hypoxanthine and thymidine. Some cultures (●) were treated with platelet extract (150 μg ml^{-1}) containing partially purified PDGF and hypoxanthine and thymidine for 2-h periods at the times indicated by the shaded bars or were left untreated (○). ^{3}H-TdR (5 μCi ml^{-1}; final concentration 0.3 Ci mmol^{-1}) was added to these cultures 10 h after the removal of the methotrexate. The cells were fixed at the indicated times and processed for autoradiography. The data are plotted according to the method of Smith and Martin[24]. The dashed line is shown to mark the beginning of mitosis (see Fig. 1).

The present data clarify the role of PDGF in regulating fibroblast growth by demonstrating that this hormone has two activities. PDGF can act during the late stages of the cell cycle, or shortly after mitosis, to prevent BALB/c 3T3 cells from entering G_0. It can also act on G_0-arrested cells to promote exit from the quiescent state. A brief treatment of quiescent cells with PDGF stimulates a single replicative cycle.

Treatment of parental cells with PDGF, during or after the S phase, allows the daughter cells to synthesise DNA. One possibility is that PDGF stimulates 'G_0-specific' events concomitantly with S, G_2 and M phases. In such a case, G_0 might not represent a true growth arrest state, but would merely reflect a series of time-dependent events which must occur in all cell cycles before DNA synthesis. The increased lag period noted in post-mitotic quiescent cells would represent the time required to complete these events. However, the addition of PDGF to the daughter cells immediately after parental mitosis also prevents growth arrest, with cells entering the S phase after a short lag period (Fig. 3*d*). Further delay in the addition of PDGF causes cells to become quiescent (Fig. 3*e*). Thus, cells enter G_0 if they are not treated with PDGF before a critical period in the replicative cycle, approximately 3–5 h after the beginning of mitosis. Addition of PDGF after this period does not prevent entry into G_0, but releases cells from G_0, a process which requires an additional 5 h before entry into the S phase. Clearly, PDGF does not simply cause 'G_0-specific' events to be telescoped into the preceding cell cycle. The evidence supports the concept that G_0 is a distinct growth arrest state which cells can enter some time after mitosis.

We thank Dr C. Frantz for reviewing the manuscript. This work was supported by grants from NIH. C. D. Scher is a Scholar of the Leukemia Society of America.

Metabolites of diethylstilboestrol induce sister chromatid exchange in human cultured fibroblasts

Diethylstilboestrol (DES) is one of the few substances for which a clear association with carcinogenicity has been established in man[1,2]. Nevertheless, it is still widely used, mainly as a cheap oestrogen to increase the slaughter weight of beef[3], but in spite of this it is not known if residues in the meat or metabolites excreted by the cattle are hazardous to man. It is also unknown whether there is a threshold dose below which DES is harmless. A threshold might be expected if a hormonal mechanism of carcinogenesis rather than metabolic activation to an electrophilically reactive species operates. This possibility was supported by the observations that DES, in contrast to most other carcinogens, failed to induce mutations in the *Salmonella*/microsome test[4–6] or malignant transformations of eukaryotic cells in culture[7]. It is also disturbing that DES, one of the few known human carcinogens was negative in these two most widely used short-term tests introduced as fast early-warning systems for potential carcinogens. We now report that DES is positive in sister chromatid exchange (SCE) induction, a short-term test for which a high correlation with the carcinogenicity of the compounds tested has been observed[8–10]. Moreover, we show that metabolic activation was involved. Two different pathways leading to metabolites much more active in SCE induction than DES itself ('proximate agents') were established.

DES-α, β-oxide and β-dienoestrol (Fig. 1) were synthesised as described previously[11]. The mutagenicity test was performed as described by Ames[12]. As mammalian metabolising system S-9 mix[12] from liver homogenate of Aroclor 1254-treated male Sprague–Dawley rats (200–300 g) was used. Fibroblast cultures were established[13] from skin biopsies of the inner side of the upper arm of healthy male and female volunteers of Caucasian origin. 5-Bromodeoxyuridine (30 μg ml^{-1}) and the test compound were incubated with the cells for 72 h. After staining with acridine orange[14], SCE was directly evaluated under a fluorescent microscope.

The initial experiment revealed that DES induces SCE. The number of SCEs was increased even at low doses with a further shallow increase as the DES concentration is raised (Fig. 2, open symbols). The results obtained with diploid fibroblast cultures of five different donors were very similar. Interestingly, lower concentrations of DES were sufficient to cause SCE than of the positive control benzo (*a*) pyrene (Table 1). To clarify whether DES induces SCE itself or whether it requires metabolic activation, we used two methods—inhibition of metabolism and test of metabolites for induction of SCE. Several pathways of DES metabolism are known[11,15]. All include some chemically reactive intermediates: (1) hydroxylation *ortho* to the phenolic hydroxyl groups leads to highly reactive catechols; (2) oxidation of the olefinic α, β-double bond produces an electrophilically reactive epoxide as the primary metabolite; (3) β-dienoestrol, a quantitatively important metabolite is formed by peroxidases, probably via highly reactive semiquinones and quinones. β-Dienoestrol can be further oxidised to ω-hydroxy-β-dienoestrol which can form reactive esters. At first, we tested two key metabolites, DES-α,β-oxide and β-dienoestrol (structures shown in Fig. 1). We observed an increase of SCE at even lower concentrations of test compound than with DES (Fig. 2). Dual reciprocal plots of the SCE induced against the concentration of

Table 1 SCE-induction by DES and metabolic intermediates

Test compound	Maximum SCE per metaphase	Concentration for half maximal induction for SCE*	Potency†
DES	11.0	133 nM	1
DES-α, β-oxide	18.2	40 nM	9.6
β-Dienoestrol	16.8	5 nM	70
Benzo(*a*)pyrene	15.7	2,100 nM	0.14

SCEs were investigated as described in Fig. 2 legend. Controls showed 7.2 ± 0.9 (s.d.) SCE per metaphase.

* Values are calculated from dual reciprocal plots by linear regression analysis. The *r*-values were >0.97.

† The maximal number of SCE which were caused by the test compound (minus the number of spontaneous SCE) was divided by the concentration of test compound which caused the half-maximal effect. This value was divided by that of DES and is used as measure of the ability of the compound to cause SCE.

0028–0836/79/400392—03$01.00

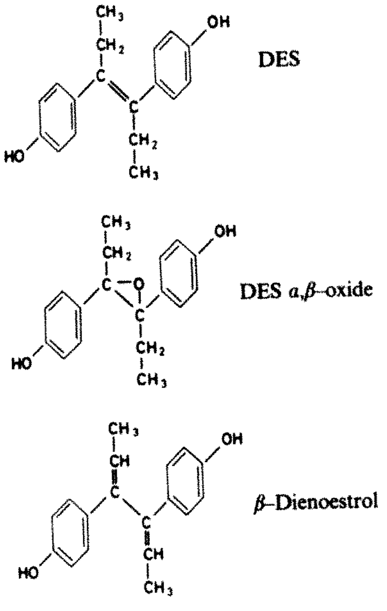

Fig. 1 Chemical structure of diethylstilboestrol (DES), and the two metabolites used for SCE induction.

inducing substance were used to calculate the maximum frequency of SCE and the concentrations for half maximal SCE induction (Table 1). The much higher potency of the metabolites strongly suggests that the induction of SCE by DES requires a metabolic activation. As we had previously shown[16] that the metabolic activation of benzo(*a*)pyrene to a derivative inducing SCE can be inhibited by α-naphthoflavone, which inhibits mono-oxygenases[17], we determined the SCE induction by DES and two metabolites in the presence of α-naphthoflavone (Fig. 3). The induction of SCE normally observed with DES was completely inhibited by α-naphthoflavone and was markedly reduced when α-naphthoflavone was added together with β-dienoestrol. The SCE-induction obtained with DES-α, β-oxide, however, could only be lowered about 35% by the presence of α-naphthoflavone. This provides additional evidence that DES and also β-dienoestrol require metabolic activation by mono-oxygenase for the induction of SCE.

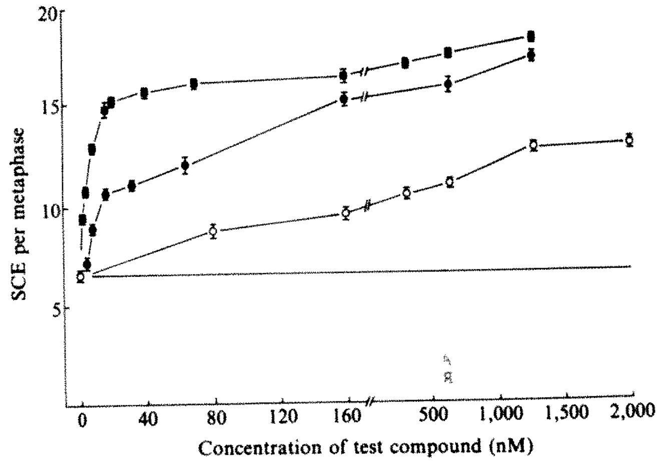

Fig. 2 SCE induction by DES (○) DES-α, β-oxide (●) and β-dienoestrol (■). The test compounds were dissolved in ethanol and then mixed with a twofold excess of sterile fetal bovine serum (FBS). Various amounts of these stock solutions (which were at least 100-fold concentrated as compared to the final dilution in the culture medium) were added to 25 cm^2 cell culture flasks (Falcon) containing 5×10^5 cells together with 5 ml Dulbecco's modified Eagles medium (GIBCO), supplemented with 10% FBS (GIBCO), 2×10^5 IU l^{-1} penicillin, 0.1 g l^{-1} neomycin and 0.1 g l^{-1} streptomycin, and buffered with 20 mM HEPES and 0.5 g l^{-1} $NaHCO_3$. The concentration of ethanol in the culture medium did not exceed 0.5%. Controls received 0.5% ethanol only.

Recently it was reported that DES can induce unscheduled DNA synthesis[18] in HeLa cells, and induces mutations[19] in a mouse lymphoma cell line. However, both effects could only be demonstrated over a very narrow, already markedly cytotoxic dose range and quantitative reproducibility was poor. Thus, neither test is suitable for studying factors which determine susceptibility towards DES. In contrast, SCE induction by DES in human diploid fibroblasts shown in this study did occur at very low doses and was dose-dependent over a wide range of concentrations. Thus the system could be used to investigate whether metabolic activation was involved, and to discover pathways leading to metabolities more active in SCE induction than DES itself ('proximate agents').

Table 2 Reversion of *his*⁻ *S. typhimurium* to histidine prototrophy

		his⁺ colonies per plate (range)			
Test compound (μg per plate)	S-9 mix	TA 100	TA 1535	TA 1537	TA 98

1 Benzo(*a*)pyrene 4, 5-oxide	−	2,340–4,000	21–31	620–700	5,000–5,700
10 *N*-Methyl-*N*′-nitro-*N*-nitrosoguanidine	−	50,000–61,000	45,000–80,000	68–115	38–41

Histidine-dependent bacteria (*S. typhimurium* strain TA 100, TA 1535, TA 1537 or TA 98), test compound (dissolved in 10-30 μl dimethyl sulphoxide with or without a mammalian metabolising system (S-9 mix from liver homogenate of Aroclor 1254-treated rats) were poured with a histidine-poor top agar on minimal agar plates. Colonies (*his*⁺ revertants) were counted after incubation for 3 d at 37 °C. DES and its metabolites were tested in duplicates at the following doses: 3.15; 10; 31.5; 100; 315; 1,000 and 3,000 μg per plate. The table shows the range of the number of colonies at those doses where neither a significant reduction of the number of *his*⁺ colonies nor of the *his*⁻ background lawn was observed. Each individual experiment with S-9 mix contained benzo(*a*)pyrene, 2-aminoanthracene, 3-methylcholanthrene and solvent controls. Each experiment for direct mutagenicity contained benzo(*a*)pyrene 4, 5-oxide, *N*-Methyl-*N*′-nitro-*N*-nitrosoguanidine and solvent controls. Values for these controls represent ranges of all the experiments used for this study.

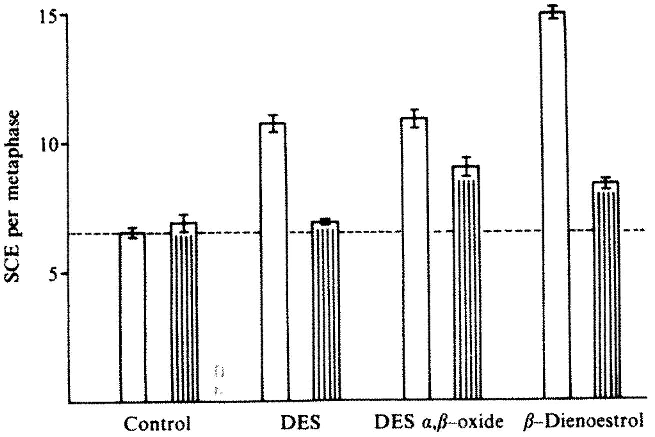

Fig. 3 Effect of α-naphthoflavone on the induction of SCE by DES, DES-α, β-oxide and β-dienoestrol. The experiments were performed as described in Fig. 2. α-Naphthoflavone was dissolved in acetone, mixed with a 40-fold excess of FBS and added to the culture. DES was present at 1.25 μM, DES-α, β-oxide and β-dienoestrol at 20 nM. The bars show mean numbers of SCE per metaphase ±s.d. of incubations without (☐) and with (▥) α-naphthoflavone (5 $\mu g\ ml^{-1}$).

Note that the concentrations of test compound at which SCE were induced were low not only in absolute terms but also in relation to the toxicity of the compounds. With DES-α, β-oxide and β-dienoestrol cytotoxic effects that lead to an altered microscopic appearance of the cells and to a reduced number of metaphases were observed only at concentrations more than 100-fold greater than those needed for a marked SCE induction. The induction of SCE at doses which are much lower than those needed for observing toxicity favour the assumption that the exchanges of DNA fragments observed as SCE reflect specific DNA-directed damage rather than DNA alterations as an effect of broad disturbances of cell growth.

These results showed that some metabolites of DES are much more potent inducers of SCE than DES itself, so we investigated if these metabolites could induce mutations in *Salmonella typhimurium* either directly or after activation by mammalian tissue preparations. Table 2 shows that neither DES nor the two metabolites DES-α, β-oxide and β-dienoestrol induced any mutations to histidine prototrophy with *his* *S. typhimurium* strains in conditions where *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine and benzo(*a*)pyrene-4,5-oxide (in the experiments for direct mutagenicity) and benzo(*a*)pyrene, 3-methylcholanthrene and 2-aminoanthracene (in the presence of S-9 mix) strongly increased the number of his^+ revertant colonies.

Our results show that from DES at least two metabolic routes lead to metabolites which cause SCE: (1) via or to DES-α, β-oxide; (2) via β-dienoestrol which is further activated by monooxygenase. The activation via β-dienoestrol led to much stronger SCE effects than the activation via DES-α, β-oxide. In this context it is interesting that organs susceptible to DES carcinogenesis possess high activities of peroxidase[20], which metabolises DES to β-dienoestrol. The demonstration of metabolic activation of DES for SCE induction does, of course, not exclude that hormonal mechanisms and stimulation of cell proliferation may be important contributors to its carcinogenic effects.

The reasons why results with SCE are not reproduced in the Ames test are not clear. It may be that the *S. typhimurium* assay cannot detect mutations caused by DES metabolites as it is a back-mutation assay or because the exchange of identical genetic material during the SCE may not lead to mutation. Alternatively, metabolic factors may be involved—for example, enzymes (such as conjugating enzymes) may be required for the activation of DES which are active in human fibroblasts but not in the dilute postmitochondrial liver fraction in the plates of the bacterial mutagenicity test. Or conversely, enzymes may be present in the S-9 mix which efficiently inactivate the active DES-metabolites.

The induction of SCE in fibroblasts by DES is an *in vitro* system which will be of value as a tool for the study of the mechanisms of activation and inactivation of DES and the reasons why it is inactive in other *in vitro* systems and in many organs *in vivo*[3,21].

This work was supported by the Deutsche Forschungsgemeinschaft.

Note added in proof: On 28 June 1979 the FDA banned the use of DES as a growth promoter in cattle and sheep.

Identical 3′ non-coding sequences in five mouse Ig κ chain mRNAs favour a unique C_κ gene

Nicholas M. Gough, Suzanne Cory & Jerry M. Adams

Molecular Biology Laboratory, The Walter and Eliza Hall Institute of Medical Research, PO Royal Melbourne Hospital, Victoria 3050, Australia

The constant regions of immunoglobulin κ chains are encoded by a very small but unknown number of genes. The kinetics of nucleic acid reassociation is consistent with up to four C_κ genes per haploid mouse genome[1–4], while saturation hybridisation suggests that there are two C_κ genes[5]. The amino acid sequences proposed for seven κ C regions do differ slightly[6–10], but at least some of these differences result from sequencing errors[11]. Determining the nucleotide sequence of the C region of κ mRNAs[11] and the adjacent 3′ non-coding region should more readily reveal any slight differences reflecting a multiplicity of C_κ genes. Examination of the 3′ non-coding region may be particularly useful, as this region is not constrained to encode the largely invariant C_κ amino acid sequence. Sequences reported for the 3′ terminal regions of two κ mRNAs, MOPC 21 (refs 11, 12) and MOPC 41A (ref. 13), were identical for the first 59 residues, but the subsequent, tentative, 45 residues proposed for MOPC 41A mRNA differed from the MOPC 21 sequence. It was unclear, however, whether these differences resulted from methodological problems, or genuine sequence divergence. We have therefore re-examined the MOPC 41A 3′ terminal sequence in a direct comparison with that of MOPC 21 and also determined 3′ terminal sequences of about 100 residues in three other κ mRNAs. We confirm here the sequence presented by Hamlyn *et al.*[11] for the MOPC 21 mRNA and show that not only the MOPC 41A mRNA, but also the three other κ mRNAs have the same sequence.

0028–0836/79/400394—03$01.00

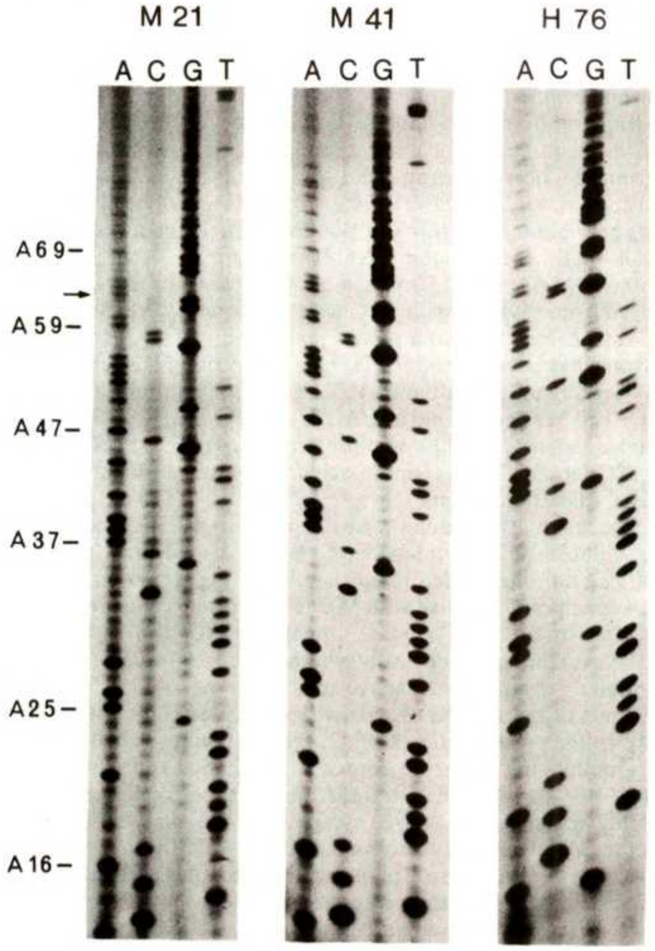

Fig. 1 Polyacrylamide gels used to determine sequences complementary to the 3′ termini of MOPC 21, MOPC 41A and HPC 76 κ mRNAs. The oligonucleotide d(pT_{10}-C-A) was used as primer, in a fourfold molar excess over the mRNA templates which were isolated as described previously[24,25]. cDNA was synthesised in 6-μl reactions containing 50 mM Tris-Cl *p*H 8, 50 mM KCl, 8 mM $MgCl_2$, 10 mM dithiothreitol, 2 μM [$\alpha-{}^{32}P$]dATP and about 2 units of reverse transcriptase. Dideoxynucleotide triphosphates (P-L Biochemicals) and the corresponding dNTPs were in the following molar ratios: ddATP:dATP, 2.7:1; ddCTP:dCTP, 1.3:1; ddGTP:dGTP, 0.6:1; ddTTP:dTTP, 0.7:1. Incubation was at 39 °C for 15 min, followed by a 'chase' reaction containing 200 μM of each of the four dNTPs (39 °C, 15 min). Samples were denatured in formamide and loaded onto a 0.35-mm thick 12% polyacrylamide gel[26] containing 7 M urea, 90 mM Tris-borate, 2.5 mM EDTA. Electrophoresis was for 2.5 h at 30 mA and autoradiography at −80 °C. The arrow indicates a position at which Hamlyn *et al.*[11] have suggested a correction to their previously published sequence for the MOPC 21 κ mRNA[12], the elimination of a C residue; our results confirm this correction.

Sequences were derived by an adaptation[14,15] of the dideoxynucleotide procedure for sequencing DNA templates[16]. Complementary DNA was transcribed using the oligonucleotide d(pT_{10}-C-A)[12] as primer. Figure 1 shows examples of autoradiographs of polyacrylamide gels used to determine sequences complementary to the 3′ terminal regions of three κ mRNAs. Clearly, the patterns of bands shown are identical. These gels allowed sequences of about 60–70 nucleotides to be determined. By manipulating the concentrations of the chain-terminating dideoxynucleotides and the time of electrophoresis, sequences of over 100 residues could be obtained. The sequences derived for the five mRNAs examined, and for MOPC 21 (ref. 11), are shown in Fig. 2. At no position did any of the sequences differ distinctly from that of MOPC 21. There were a few positions towards the ends of the sequences where we could not clearly distinguish between two nucleotides, but in each case, one of the choices was that found in the MOPC 21 sequence.

The known 3′ terminal sequences in mammalian mRNAs show considerable differences[11,17–21]. Even between the mRNAs encoding the closely related human and rabbit α-globins and human, rabbit and mouse β-globins there are distinct sequence and length differences within this region[17–20]. It has been suggested that these regions may not have a precise sequence-dependent function[21]. The apparent identity of the five κ non-coding regions is therefore unlikely to result merely from strong evolutionary selection for a specific sequence, but rather favours the suggestion that there is only one mouse C_κ gene. If there were two C_κ genes which differed in the region examined and were expressed with equal frequency, the chance that five sequences would be of one type is 1 in 16; similarly, for three C_κ genes, the chance would be 1 in 81. Naturally, our results would say little about the possibility of a C_κ gene expressed infrequently in myelomas.

Nucleotide sequences reported for a substantial portion of the C region in two κ mRNAs (MOPC 21 (ref. 11) and MOPC 149 (ref. 22)) are identical and contain no 'silent' base changes, providing further evidence in favour of a unique C_κ sequence. Similarly, the detailed restriction endonuclease cleavage maps of seven different cloned κ mRNA sequences are identical throughout the *C* region (N.M.G., E. Webb and J.M.A., in preparation).

It seems remarkable that no differences have been detected in the C_κ regions examined, as the plasmacytomas from which they were isolated are of independent neoplastic origin and have been serially transplanted for many years. This suggests that if there is a somatic mechanism for generating V region diversity[23], it must either be directed specifically to the V region genes, or no longer be operational within the terminally differentiated plasma cell.

We thank Drs M. Smith and S. Gillam for primer d(pT_{10}-C-A), Dr J. Beard for reverse transcriptase, Dr N. Warner for HPC 76, Drs G. Brownlee and G. Air for advice, and Miss Jan Holton for technical assistance.

Fig. 2 DNA sequence complementary to the 3′ non-coding region of five κ light chain mRNAs. The mRNAs were from the tumours MOPC 41A, McPC 603, S107 (reviewed in ref. 27), HPC 76 and from the P3 cell line[28] (derived from the tumour MOPC 21). The MOPC 21 κ sequence (*) is taken from the complete sequence of Hamlyn *et al.*[11]. The solid lines indicate the regions examined in the other mRNAs which had sequences clearly identical to that of MOPC 21. Bands were usually not detected at positions corresponding to the first few residues after the primer, as is often found with this technique. At positions where there was ambiguity the possible residues are given. In the HPC 76 sequence there was one position (N) where a band occurred in the equivalent position in all tracks. The arrow indicates the position at which a C residue had previously been assigned[12] (see Fig. 1).

A normal cell protein cross-reactive to the major Abelson murine leukaemia virus gene product

Owen N. Witte, Naomi E. Rosenberg* & David Baltimore

Department of Biology and Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 and *Cancer Research Center, Tufts University School of Medicine, Boston, Massachusetts 02111

Abelson murine leukaemia virus (A-MuLV) is a replication-defective retrovirus capable of rapid *in vivo* and *in vitro* transformation of bone marrow lymphoid target cells. A-MuLV was isolated from a steroid treated BALB/c mouse inoculated with the replication competent Moloney-MuLV (M-MuLV)[1–4]. The A-MuLV genome (5.5 kilobases) retains regions of precise homology to M-MuLV at its 5′ end (1,320 bases) and 3′ end (730 bases). The centre of the A-MuLV genome (3,500 bases) is non-homologous to M-MuLV and presumably represents unique sequences derived from the mouse genome by a recombinational event[5]. The only known protein encoded by the A-MuLV genome is one of MW 120,000, called P120 (refs 6, 7). About one-quarter of this protein is encoded by the 5′-terminal M-MuLV-related sequences and the rest is encoded by the A-MuLV unique sequences. P120 has been found in all cell lines transformed by the strain of A-MuLV that originally derived from ANN-1 cells[2], including transformed non-producer cells. P120 can be translated *in vitro* using A-MuLV genomic RNA as messenger RNA. P120 is a phosphoprotein but there is no evidence for glycosylation[6,8,9]. We have used an anti-A-MuLV syngeneic tumour regressor serum with defined specificities to search for cross-reacting normal cellular proteins. We have identified a protein of MW 150,000 (NCP150) in metabolically labelled thymus and other lymphoid organs. NCP150 by absorption and competition analysis is closely related to the unique region of the A-MuLV P120 protein.

Mouse syngeneic tumour regressor antiserum with high reactivity to the A-MuLV unique region of P120 was prepared. After absorption to remove M-MuLV protein reactivity this antiserum contains residual activity for P120 demonstrated by direct immunoprecipitation and tumour cell surface immunofluorescence[9]. This A-MuLV tumour regressor serum (anti-AbT serum) was used to search by immunoprecipitation for normal cellular proteins.

Explants of mouse lymphoid tissues were labelled for 1 h with ^{35}S-methionine, extracted, immunoprecipitated with anti-AbT serum or normal serum and examined by electrophoresis through an SDS-polyacrylamide gel. A protein of MW 150,000 was precipitated by anti-AbT but not normal serum (Fig. 1); we shall call the protein NCP150 (normal cell protein, 150,000 MW). NCP150 was most prominent in extracts prepared from thymus tissue but smaller amounts were detectable in spleen and bone marrow. Precipitation of NCP150 from thymus has been reproducible; no other protein has reproducibly been reactive with anti-AbT serum but not normal serum. NCP150 has been found in BALB/c, C57BL/6, C57L and SJL mouse strains. No additional proteins were found if ^{3}H-leucine or ^{14}C-labelled mixed amino acids were used to label thymus tissue (data not shown).

The reactivity of our anti-AbT serum with NCP150 could not be blocked by unlabelled M-MuLV virion proteins ($100\ \mu g\ ml^{-1}$) (included in all samples in Fig. 1) nor could any sera specifically reactive with M-MuLV proteins encoded in the *gag*, *pol* or *env* gene regions[10] precipitate NCP150.

To examine more critically whether NCP150 was being precipitated by antibody reactive to the unique A-MuLV determinants of the P120 molecule, we performed competition and absorption tests. Extracts of C57BL/6 thymus labelled with ^{35}S-methionine were the source of NCP150, and extracts of 2M3 cells—an A-MuLV-transformed lymphoid cell line—were used as a comparison source of labelled P120. Anti-AbT serum in the presence of excess unlabelled M-MuLV virion proteins was used to precipitate all experimental samples and unlabelled cell extracts were used as competitor.

Normal mouse serum precipitated no NCP150 or P120 (Fig. 2, lanes *a*) and anti-AbT serum precipitated readily detectable bands of NCP150 and P120 (Fig. 2, lanes *b*). The amounts of anti-AbT serum used had been titrated to be limiting in the precipitation. When increasing amounts of unlabelled extracts of an A-MuLV-transformed non-producer NIH/3T3 cell line were included, immunoprecipitation of both NCP150 and P120 was blocked (Fig. 2, lanes *c–e*). Equivalent amounts of extract from a Moloney sarcoma virus transformed non-producer NIH/3T3 cell line did not block the specific precipitations (Fig. 2, lanes *f–h*). Extracts of NIH/3T3 cells infected with the spleen focus-forming component of the Friend mouse leukaemia virus also failed to block precipitation (data not shown). Thus competition experiments show that all of the reactivity of anti-AbT serum with NCP150 can be blocked by extracts containing P120 (A-MuLV transformed cells) and not by extracts of transformed cells that lack P120 (Moloney sarcoma virus transformed cells).

As another specificity test, we pre-absorbed anti-AbT serum with intact, viable A-MuLV-transformed non-producer NIH/3T3 cells to remove reactivity to the P120 determinants expressed on the cell surface. Such absorptions have been shown[9] to remove the ability of anti-AbT serum to stain the cell membrane of A-MuLV transformed cells; it also markedly reduced the ability of the serum to immunoprecipitate P120. Figure 2, lanes *i*, shows that precipitation of NCP150 and P120 with unabsorbed control serum was evident but lanes *j* show a markedly reduced precipitation with the serum preabsorbed by live cells. Thus, for selected batches of anti-AbT serum, most of the reactivity is with cell surface-exposed regions of P120 and these regions are also those by which NCP150 is precipitated. Whether these regions of NCP150 are cell surface-exposed remains to be determined.

These results demonstrate that NCP150 and the unique region of P120 share common antigenic determinants. The precise arrangement of these antigenic sites and molecular extent of homology between NCP150 and P120 cannot be determined using these techniques. Further work involving

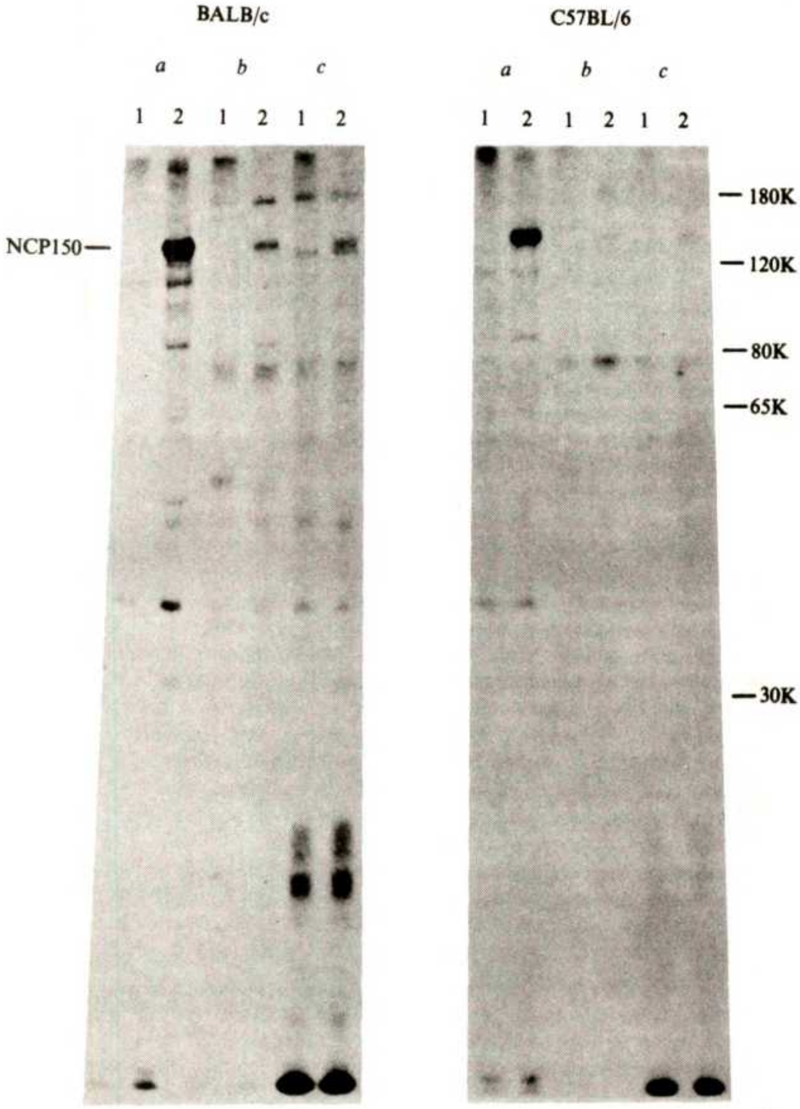

Fig. 1 Immunoprecipitation of a normal cellular protein with anti-Abelson MuLV tumour regressor serum. *In vitro* explants prepared as single cell suspensions (2×10^7 nucleated cells) of thymus (*a*), spleen (*b*) or bone marrow (*c*) from normal 5-week-old BALB/c or C57BL/6 mice were labelled with 100 μCi of ^{35}S-methionine (NEN) in 2 ml of methionine free media with 10% dialysed fetal calf serum for 1 h at 37 °C. Cells were pelleted, extracted and clarified for immunoprecipitation as previously described[6] at 10^7 cells per ml with the inclusion of the protease inhibitor phenylmethylsulphonylfluoride at 2 mM. Aliquots of 1 ml were reacted (16 h at 4 °C) with 5 μl of either normal mouse serum (lane 1) or anti-Abelson MuLV syngeneic tumour regressor serum (anti-AbT, lane 2). All tubes contained 100 μg ml^{-1} unlabelled virion proteins of Moloney MuLV. Immunoprecipitates were collected with *Staphylococcus aureus* and analysed on a SDS–10% polyacrylamide gel developed by fluorography as previously described[10]. The migration position of molecular weight standards given is shown on the right hand side.

formal peptide map comparison will be required to answer such questions.

The complete spectrum of cell types that contain NCP150 and the relative concentrations of the protein in these cells have yet to be ascertained. Using a 1-h pulse with ^{35}S-methionine, thymus certainly contained more labelled NCP150 than spleen or bone marrow (Fig. 1) but unknowns of turnover time and cellular heterogeneity make statements about relative concentrations of NCP150 premature. The detection of NCP150 in spleen and marrow is near the borderline of our present techniques. Using these techniques, cultured fibroblasts from a variety of mouse strains and liver cells have shown no evidence of NCP150. It seems likely from the present results that NCP150 shows a significant variation in concentration as a function of cell type. It also seems from comparisons of band intensities on autoradiograms that the amount of P120 is 40- to 100-fold higher per cell in A-MuLV-transformed cells than the amount of NCP150 in lymphoid tissues. Various cultured murine thymic leukaemia cells have been surveyed and while all showed evidence of NCP150, none was especially high (data not shown).

Work in the avian sarcoma virus system (ASV) has demonstrated the utility of tumour regressor antisera for identifying the normal cellular protein analogue of the transforming gene product, pp60^{src}. In the ASV system the normal cellular pp60 and viral pp60^{src} proteins were very close in molecular weight. The normal cellular pp60 was found in fibroblast tissues of a variety of avian and other vertebrate species but the amount of normal cellular pp60 was 10- to 100-fold less than pp60^{src} in ASV transformed cells[11,12]. The ASV and A-MuLV systems appear similar in that sera that recognise the transforming protein—or the putative transforming protein in the case of A-MuLV—also recognise a normal cellular constituent. The systems differ, however, in that ASV appears to contain a total cellular gene with no added viral determinants while A-MuLV has only part of a cellular gene (about 90,000 of a total MW of 150,000) attached to amino acid sequences of normal M-MuLV proteins. The systems also differ in that the messenger RNA and presumably the protein representing the normal *src* equivalent is present at a low but consistent level in all cells and tissues examined[13] but NCP150 is more variable in occurrence. Both normal cell proteins occur at concentrations much lower than their counterparts in virally transformed cells.

Our results should be contrasted with those of Risser *et al.*[14]. They have prepared a similar mouse anti-A-MuLV syngeneic regressor serum and used it to identify an A-MuLV related tumour cell surface antigen by cytotoxicity. No biochemical determination of the nature of this antigen has been reported. Using lymphoid cells of normal mice in absorption tests, they reported that a cross-reacting antigen can be detected on the surface of bone marrow and spleen cells but not thymus from BALB/c and closely related strains. Unrelated strains, like C57BL/6, were negative for this normal cellular antigen. Our results with NCP150 show a different tissue distribution from that described by Risser *et al.* and we do not find any evidence of allotypy in our serum. Whether the differences between the

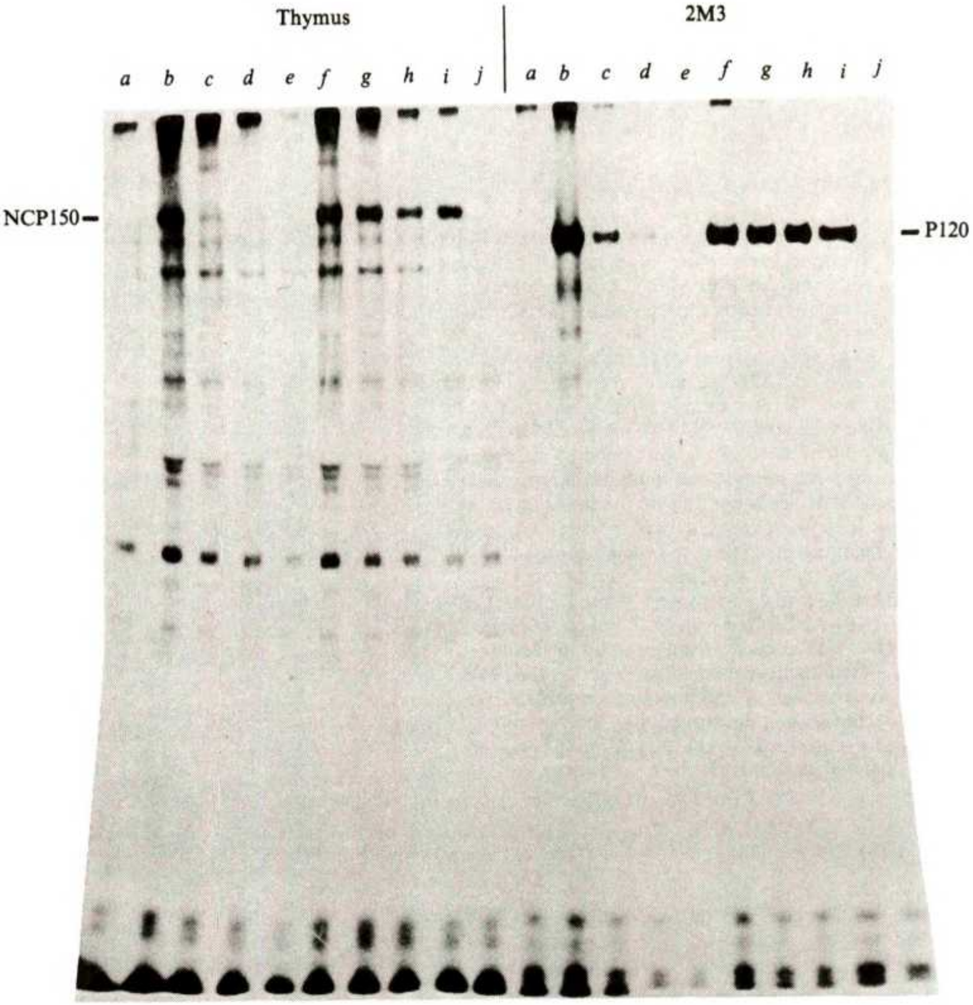

Fig. 2 Competition and absorption analysis of NCP150 and P120. Labelled cell extracts of C57BL/6 thymus and 2M3 cells (an A-MuLV *in vitro* derived clonal lymphoid cell line)[6] were prepared and analysed as in Fig. 1. A final volume of 1 ml for each cell extract of thymus (10^7 cells) or 2M3 (5×10^5 cells) was used for each tube. All tubes contained 100 μg ml^{-1} unlabelled Moloney MuLV virion proteins. Lane *a*, normal mouse serum (5 μl). Lane *b*, anti-AbT (5 μl). Lanes *c*, *d* and *e*, anti-AbT (5 μl) plus unlabelled extract of 2×10^6, 4×10^6 or 8×10^6 A-MuLV transformed non-producer NIH/3T3 cells. Lanes *f*, *g*, *h*, anti-AbT (5 μl) plus unlabelled extract of 2×10^6, 4×10^6, or 8×10^6 Moloney sarcoma virus transformed non-producer NIH 3T3 cells respectively. Lane *i*, 1:10 diluted anti-AbT (50 μl) control-mock absorbed. Lane *j*, 1:10 anti-AbT (50 μl) pre-absorbed with viable A-MuLV transformed non-producer NIH 3T3 cells (2×10^8 cells per ml diluted serum—3 cycles each 45 min; 0 °C). Immune precipitates were prepared and analysed as in Fig. 1.

results imply that we are studying different proteins remains unclear. One possibility is that Risser *et al.* were detecting NCP150 but that the synthetic rate (as monitored by immunoprecipitation) is controlled separately from expression at the cell surface (as monitored by cytotoxicity absorption).

We thank Drs Robert Weinberg and David Housman for Moloney sarcoma and spleen focus-forming virus infected non-producer NIH/3T3 cells, respectively. This work was supported by grant VC-4J from the American Cancer Society (to D.B.), grant CA-24220 from the NCI (to N.E.R.) and grant CA-14051 from the NCI (core grant to Dr S. E. Luria). O.N.W. is a Helen Hay Whitney postdoctoral fellow. N.E.R. is a Research Scholar of the American Cancer Society, Massachusetts Division. D.B. is a Research Professor of the American Cancer Society.

Clostridium botulinum can grow and form toxin at *p*H values lower than 4.6

G. J. M. Raatjes & J. P. P. M. Smelt

Unilever Research Vlaardingen, PO Box 114, 3130 AC Vlaardingen, The Netherlands

It is generally accepted[1] that in *Clostridium botulinum* both growth and toxin formation are completely inhibited at *p*H values below 4.6. This critical *p*H value has been confirmed by many investigators using food as substrate[2–5] or culture media[3,6–8]. Occasionally[9–12] growth of *C. botulinum* and toxin formation at *p*H values lower than 4.6 have been reported. In these cases the authors ascribed the unexpected outgrowth and toxin formation to local *p*H differences in inhomogeneous media and growth of *C. botulinum* before *p*H equilibration, or to the fact that fungi created microenvironments within or adjacent to the mycelial mat, where the *p*H was higher than 4.6 as was demonstrated by Odlaug and Pflug[11,12]. We show here that the general assumption that *C. botulinum* does not grow below *p*H 4.6 is incorrect. We have observed that growth and toxin formation by *C. botulinum* can take place in homogeneous protein rich substrates (containing 3% or more soya or milk protein) at *p*H values lower than 4.6.

Table 1 Influence of *p*H, type of acid, and protein content on the behaviour of *C. botulinum* type A and B, if inoculated together with *Bacillus* spores in substrates based on protein enriched soya extracts

(1) Initial inoculum 100 bacilli per ml substrate. At least hundred-fold growth of *Bacillus* in one sample (+) or two samples (++). Less than hundred-fold growth of *Bacillus* in one sample (−) or two samples (−−).

(2) Initial inoculum 1,000 *C. botulinum* per ml substrate. At least 10-fold growth of *C. botulinum* in one sample (+) or two samples (++). Less than 10-fold growth of *C. botulinum* in one sample (−) or two samples (−−).

(3) *θ*, Two samples tested for toxin, no sample toxic; I, 1/2 samples toxic; II, 2/2 toxic.

NT, Not tested.

Media in screwcap bottles containing different levels of soya or milk proteins, in which the *p*H was adjusted with various acids (Table 1), were inoculated with either a mixture of spores of *C. botulinum* type A strain 62A, Vl_1 and ZK_3 and *C. botulinum* type B strain B6 and 2345, alone or together with a mixture of spores of *Bacillus subtilis* and *B. licheniformis* isolated from soya concentrates. Details are given in Table 1.

The inoculated media were filled into screwcap bottles which were subsequently heated for 5 min at 100 °C. After cooling, the headspace in each bottle was filled with liquid paraffin. Duplicate bottles were examined at various intervals during incubation at 30 °C for growth, *p*H value and toxin; the presence of toxin was tested by intraperitoneal injection of mice.

The *p*H value did not increase from the initial values by more than 0.1 *p*H unit during incubation. Growth and toxin formation by *C. botulinum* took place at a *p*H value as low as 4.0 in the presence of the bacilli if the *p*H was adjusted with hydrochloric acid. Growth of the bacilli removed residual oxygen and lowered the redox potential, thus creating more favourable conditions for the growth of *C. botulinum*. When we compared the inhibitory action of hydrochloric, citric, lactic and acetic acids at *p*H 4.4, growth and toxin formation decreased in that order (Table 1).

The level of protein in the media also affected the ability to grow at low *p*H values—at *p*H 4.4 a minimum protein level around 3% was necessary for growth and toxin formation.

In further experiments with 5.5% soya protein J. S. Crowther (personal communication) observed that in anaerobic conditions spores of *C. botulinum* are able to outgrow and form toxin at *p*H 4.2 (if hydrochloric acid was used as acidulant) in the absence of other microorganisms. However the results at this *p*H were not always repeatable.

So far we have not found *C. botulinum* to grow in a wide range of actual foods with *p*H value lower than 4.6, but the assumption that *C. botulinum* does not grow below *p*H 4.6 has been shown to be incorrect, and the understanding of conditions in which growth may occur, requires further study.

Superoxide involvement in the bactericidal effects of negative air ions on *Staphylococcus albus*

E. W. Kellogg III*, M. G. Yost†, N. Barthakur‡ & A. P. Kreuger‡

The physical nature of small air ions is well established and it is recognised that they can produce a variety of biological effects[1]. However, in only a few instances have any underlying biochemical changes been detected[2–4]. Theoretically, one can consider the hydrated superoxide radical anion $(O_2^-)(H_2O)_n$ with $n \simeq 4$–8 as a likely candidate for a biologically active species of negative air ion[5]. The chemical and biological reactivity of superoxide is high[6] and includes a leading role in bacterial killing caused by radiation[7,8], in which superoxide dismutase (SOD), an enzyme that catalyses the reaction:

$$O_2^- + O_2^- + 2H \rightarrow H_2O_2 + O_2$$

protected markedly. Other studies have also demonstrated the bactericidal effect of O_2^- (refs 9–11). Inasmuch as the bactericidal action of small negative air ions has been repeatedly confirmed, we decided to test for the involvement of O_2^- in this phenomenon by evaluating the protective effect of SOD. Our results show strong O_2^- involvement in negative air ion bacterial kill.

Figure 1 illustrates the apparatus used in our experiments. To ensure that all negative ions went through the solution to the ground wire, we insulated the ground wire using heat shrink tubing and Teflon tubing to a point well below the solution's surface. A Modulion corona discharge type negative ion generator provided the ionising potential; to maintain a uniform current we adjusted the ionising potential using separate variable transformers on the a.c. lines of each generator.

Inoculated flasks, containing *Staphyloccus albus* at ~10^6 cells per ml in 40 ml of sterile 3.75 mM NaCl with 1.25 mM KPi, *p*H 7.8 buffer, were maintained at 22 ± 1 °C in a waterbath for the duration of the experiment. A vacuum pump with airflow regulator exhausted air from the flasks at a rate of approximately 500 ml per min. Aliquots of 1 ml were removed hourly, serially diluted, and then plated as previously described [12].

We isolated superoxide dismutase from bovine liver using the procedure of McCord and Fridovich[13]. This yielded pure enzyme of high specific activity (~3,500 U ml^{-1}). Catalase (Boehringer Mannheim) was extensively dialysed before use. Enzymes were sterilised by passage through a Millipore filter immediately before addition to the bacterial inoculum.

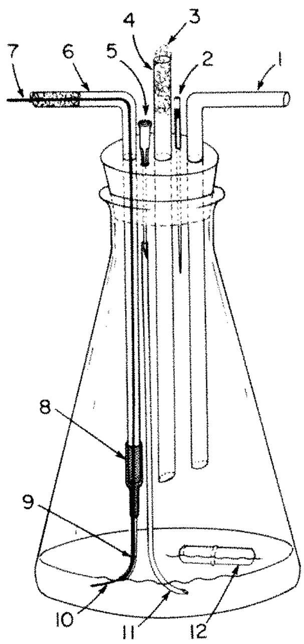

Fig. 1 1, Air exhaust tube. 2, Ion discharge needle. 3, Cotton plug. 4, Air inlet tube. 5, 18 gauge hypodermic needle. 6, Ground wire tube. 7, Ground wire. 8, Heat shrink tubing. 9, 1-mm Teflon insulating tube. 10, Bare platinum tip. 11, 1-mm Teflon sample tube. 12, Magnetic stirring rod. The apparatus was constructed in a 500 ml Erlenmeyer flask fitted with a no. 10 rubber stopper.

Table 1 shows that the exposure of bacteria to negative air ions caused a substantial loss in viability in as short a period as 2 h, with a total loss of viability seen after 5 h of ion treatment. Control samples, incubated in identical conditions but with no negative ionisation, retained full viability after 5 h. Addition of 10 μg ml^{-1} SOD protected bacteria completely against negative ion killing while catalase or denatured SOD had no significant protective effect. The lack of effect of catalase in this system appears in marked contrast to that seen in most systems which involve O_2^- toxicity. For example, both O_2^- and H_2O_2 were required for lipid peroxidation or erythrocyte lysis[14] where their toxicity manifests through their interaction to produce hydroxyl radical and singlet oxygen. In the case of negative air ion bacterial kill the toxicity of O_2^- appears H_2O_2 independent. A possible mechanism might involve O_2^- acting as a nucleophile on the phospholipid bilayer, causing a de-esterification of fatty acids[15]. This could lead to an increase in surface charge and a weakening of the membrane, which under hypotonic conditions might lead to cell lysis and death.

The experiments reported here support the concept that the negative air ions responsible for bacterial death consist solely or in part of hydrated superoxide anions. Paradoxically, while negative air ions have a reputation as a rather beneficient species[1], superoxide radical anion apparently acts as one of the

Table 1 Bacterial kill by negative air ions (% viability)

Conditions	Incubation time (h) 0	1	2	3	4	5
No (−) ions (control)	100	123 ± 3.4	115 ± 22.5	112.5 ± 1.0	111.6 ± 22.3	105.6 ± 11.0
(−) Ions	100	116 ± 3.5	72.3 ± 9.9	29.2 ± 24.9	2.5 ± 2.3	0

most toxic species produced in aerobic metabolism[6]. Perhaps the resolution of this paradox lies in the relative amount of O_2^- required for an effect. Negative air ions can cause physiological effects at extremely low levels, with clean country air having a negative ion concentration of only about 10^3 cm^{-3}, an amount which more closely parallels that of pheromones than of chemical reactants. In our system we have greatly amplified the flux of negative ions to a level which could produce, theoretically at least, 0.3 mmol O_2^- per h, which we channelled through a total of 40 ml of solution. Even so, *in vitro* systems testing for O_2^- reactivity have invoked a flux hundreds of times greater. Thus the effects of superoxide as a negative air ion although dependent on its chemical reactivity may be greatly amplified by a biological sensitivity in the hormonal range. Our tentative identification of $(O_2^-)(H_2O)_n$ as the negative air ions responsible for killing micro-organisms should provide a more solid base for investigating the effects and mechanisms of negative air ion effects in other biological systems.

† Laboratoire de Biologie Moléculaire Végétale associé au CNRS (LA, 40) Bât. 430, Université Paris-Sud, 91405 Orsay, France

We have previously regenerated tobacco plants from fused protoplasts isolated from two varieties of *Nicotiana tabacum*. The parent cells had distinct morphological nuclear and cytoplasmic markers, enabling us to recognise, among the whole regenerated plants, those with a single parental nucleus and a hybrid cytoplasm produced by the mixing of the two parental cytoplasms[1]. Genetic analysis of their progeny has confirmed that the phenotypes of these cytoplasmic hybrids (or cybrids) are stable and maternally inherited. Analysis with restriction endonuclease has shown that only one or the other parental chloroplast DNA is present in the progeny of the cybrids[2]. We report here, however, that the mitochondrial (mt) DNAs of cybrids are different from those of the parents and from the mixture of the two. The new DNAs result from mitochondrial recombination.

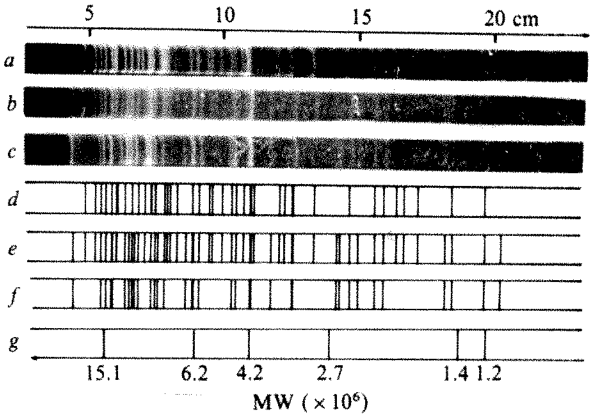

Fig. 1 Agarose slab gel electrophoresis of *Sal*I digests of mtDNAs from: *a*, Ts or *N. tabacum* var. Techne (*debneyi* cytoplasm); *c*, Xf or *N. tabacum* var. Xanthi (*tabacum* cytoplasm); *b*, mixture of Ts and Xf. These diagrams are schematically represented on *d*, (Ts); *e*, (Ts + Xf); *f*, (Xf). *Hind*III fragments of λ DNA (g) were used as standards for molecular weight determinations. Mitochondria were isolated as previously described[5] with the following modifications. Green leaves were used because etiolated material cannot be obtained with tobacco. DNase-treated organelles were purified by centrifugation on two layers of 30 and 60% sucrose. mtDNA was extracted as described for cp-DNA[6,7] and purified by linear CsCl–ethidium bromide gradient centrifugation for 2 d at 32,000 r.p.m. in a SW41 rotor. This gives cleaner mtDNA bands than does the two-step procedure used before. *Sal*I enzyme was prepared according to R. J. Roberts (unpublished). Experimental conditions for mtDNA digestion, agarose gel electrophoresis and UV fluorescence photography were as described[5,7].

Cytoplasmic hybrids were obtained from fusion between protoplasts of *N. tabacum* var. Xanthi (Xf) which has normal fertile flowers and petiolated leaves, and *N. tabacum* var. Techne (Ts), which has abnormal flowers with cytoplasmic male sterility, producing no pollen. The Ts variety, obtained from the interspecific cross *N. debneyi* × *N. tabacum*, has the cytoplasm of the former and the nucleus of the latter. The resulting nucleocytoplasmic interaction is responsible for the male sterility. Ts has sessile leaves, and in our experimental system leaf shape is the nuclear marker and flower shape the cytoplasmic marker. Details of the parents and cybrids are shown in Table 1.

Restriction endonuclease was used to analyse mtDNAs extracted from the progeny of nine cybrids (six Ti and three Xi) which represent all the variability of the new i phenotypes (see legend to Table 2). Mitochondria and mtDNAs were isolated as described in Fig. 1 legend.

Figure 1 shows the *Sal*I restriction patterns for mtDNA from the Ts (*a*) and Xf (*c*) parents showing 38 and 31 fluorescent bands, respectively. Of these, 20 appear to be common to *N. debneyi* and *N. tabacum* mtDNAs, 18 specific to Ts (*N. debneyi*) mtDNA and 11 specific to Xf (*N. tabacum*) mtDNA, as shown by comparison of Ts, Xf and Ts + Xf schematic diagrams (Fig. 1). Consequently, the diagram corresponding to a mixture of the two parent mtDNAs has 49 bands (Table 2). We found that the two varieties of *N. tabacum*, Xf and Tf (fertile Techne containing the *N. tabacum* cytoplasm), had identical mtDNAs. Figures 2 and 3 show the *Sal*I restriction patterns of mtDNAs

Table 1 Genotypes and phenotypes of parent and cybrid plants

Name		Genotypes		Phenotypes	
		Nucleus	Cytoplasm	Leaf	Flower
Parents	Ts	*N. tabacum* var. Techne	*N. debneyi*	Sessile	Abnormal; male sterile type s
	Xf	*N. tabacum* var. Xanthi	*N. tabacum*	Petiolated	Normal; male fertile type f
Cybrids	Ti	*N. tabacum* var. Techne	hybrid *N. debneyi* × *N. tabacum*	Sessile	Intermediate between those of the parents

Xf, Tf: Varieties with *tabacum* cytoplasm, normal and fertile flowers. Ts: Variety with *debneyi* cytoplasm, abnormal and male sterile flowers with split corolla, short stamen filament ended by a stigmate. Tsp: Control plant: plant regenerated from Ts protoplast with abnormal and male sterile flowers identical to Ts parent ones. Ti and Xi: cybrid plants are defined in Table 1. i Types: I, normal corolla, filament shorter than the normal, anther with some pollen: fertile. II, slightly nicked petals, long filament with flat anther: the most often sterile. III, nicked petals, long filament with distorted anther: sterile. IV, split corolla, short filament ended by white outgrowths: sterile.

* Approximate molecular weights obtained as described in the text.

isolated from the progeny of the regenerated cybrids Ti and Xi, obtained by crossing, respectively, female Ti × male Tf and female Xi × male Xf. Each of the nine cybrids in Table 2 contained a unique mtDNA distinguishable from both parent mtDNAs and from a mixture of the two. However, the cybrid patterns always contained mtDNA fragments belonging to both parents, and also, in all but one, new bands appeared. The number of bands on the cybrid diagrams varied from 35 to 41, confirming that these mtDNAs were not products of the addition of two parental mtDNAs.

The complexity of the restriction patterns precludes accurate determination of molecular weight. Nevertheless, estimates obtained by summing the molecular weights of the bands (band multiplicities are not taken into account and it is difficult to determine precisely the size of the larger fragments) show that the cybrid mtDNAs more closely resemble the Ts mtDNA than the Xf mtDNA or the mixture of parental mtDNAs (Table 2). Table 2 also shows for each cybrid mtDNA the distribution of the specific and common parental bands. There is clearly a correlation between flower shape and male sterility or fertility and the ratio of the specific *N. debneyi* and *N. tabacum* bands: an increase in the degree of sterility in the different i phenotypes of the cybrids corresponds to an increase in the number of *N. debneyi* specific fragments.

The fate of mtDNA after the initial fusion of *N. debneyi* and *N. tabacum* cytoplasms is strikingly different from that of chloroplast DNA in our cybrid plants[2]. Our results, together with previous observations of maternal inheritance and stability of floral markers, constitute evidence that new cytoplasms characterised by specific mtDNAs arise from protoplast fusion. Consequently, flower morphology and male sterility in tobacco must be controlled by nucleo–mitochondrial interaction. The presence of new bands in the cybrid mtDNA restriction patterns is evidence of mitochondrial recombination in somatic hybrid cells: the simultaneous presence, in the same cell, of *N. tabacum* and *N. debneyi* mitochondrial genomes is followed by mtDNA recombination because new molecular species are observed. Fonty *et al.*[3] have used restriction enzymes to analyse the mitochondrial genome of yeast cells and have provided the first evidence for physical recombination of mtDNA. They have also indicated that this event is frequent in crosses of wild type yeast cells.

The advantages of somatic cell hybridisation for studying non-chromosomal inheritance in higher plants were first pointed out by Gleba[4]. Unfortunately our knowledge of the mitochondrial genetics of higher plants is still limited by the scarcity of biochemical and genetic markers (namely resistance markers). The cytoplasmic parasexual hybrids of *N. tabacum* analysed here are identified by their floral phenotypes and also by specific mtDNAs arising from recombinations between different mtDNAs. The cytoplasmic male sterility in tobacco involves the mitochondria and can be transferred by protoplast fusion from one variety to another. These results emphasise the potential of somatic cell fusion for studying mitochondrial genetics and for increasing the cytoplasmic variability in higher plants.

We thank Dr F. Quetier for *Sal*I endonuclease and helpful discussions.

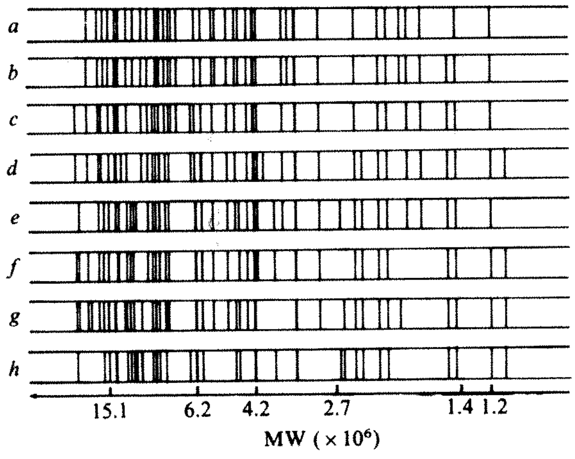

Fig. 2 *Sal*I band patterns on 0.7% agarose gel shown by the mtDNAs from parents: *a*, Ts; *h*, Xf, and from some Ti cybrids of first generation: *b*, T_{13}; *c*, T_{75}; *d*, T_1; *e*, T_{27}; *f*, T_{47}; *g*, T_{161}. Ti plants were characterised by the nuclear genome of the Ts parent (Ti plants and Ts parent presented identical leaf shape) and by hybrid cytoplasms (the flower shapes of the Ti plants were intermediate between the two parental ones). Isolation and analysis of the mtDNAs were as described in Fig. 1.

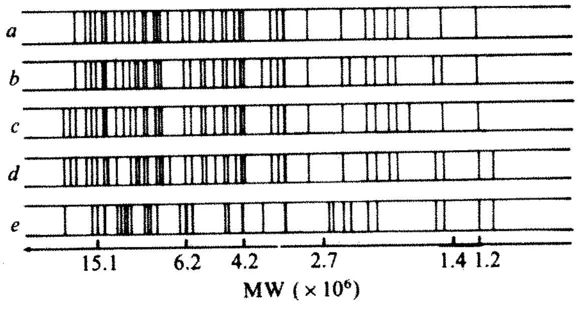

Fig. 3 *Sal*I band patterns on 0.7% agarose gel shown by the mtDNAs from parents: *a*, Ts; *e*, Xf, and from some Xi cybrids of first generation: *b*, X_6; *c*, X_7; *d*, X_1. Xi plants were characterised by the nuclear genome of the Xf parent (Xi plants and Xf parent presented identical leaf shape) and by hybrid cytoplasms (the flower shapes of the Xi plants were intermediate between the two parental ones). Experimental procedure as for Fig. 1.

Pretreatment with acetylaminofluorene enhances the repair of O^6-methylguanine in DNA

Julie D. Buckley, P. J. O'Connor & A. W. Craig

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester, UK

Epidemiological and experimental evidence suggests that the interplay of environmental factors may be particularly relevant to the induction of cancer in man[1,2]. We have investigated the possible interrelationships, at the level of DNA repair, of two chemically different hepatocarcinogens administered to rats. Animals were pretreated for several weeks by inclusion of 2-acetylaminofluorene (AAF) in the diet and a study was made of the capacity of liver to repair lesions subsequently introduced into DNA by a pulse of dimethylnitrosamine (DMN). Of particular interest was the repair of adducts at the O^6 position of guanine as this product has been implicated as a critical reaction site for carcinogenesis by the monofunctional alkylating agents[3,4]. We show here that the capacity of liver to repair O^6-methylguanine in DNA is enhanced by prolonged exposure of rats to the chemically unrelated agent, AAF.

Male Wistar rats, 7–8 weeks old and weighing ~200 g, were given (*ad libitum*) standard laboratory diet containing 0.06% AAF for three weeks and were then transferred to normal diet for the fourth week. Three such feeding cycles were administered and DMN was given at the end of the final week (Fig. 1). At this stage the animals were 19–20 weeks old and weighed ~270 g, much lower than the weight (400 g) of a normal 20-week-old colony-bred rat. This weight difference was apparently due to the lower food consumption during exposure to the carcinogen diet, as a group of animals kept throughout the 12 weeks on a schedule of equivalent daily food intake per rat also reached a body weight of about 270 g. All animals, AAF-pretreated and controls, received a single intraperitoneal (i.p.) injection of (^{14}C-methyl)-labelled DMN and were later killed at various intervals. Liver DNA was isolated and analysed as described (see Table 1 legend) to determine the amounts of O^6-methylguanine and 7-methylguanine as a proportion of the parent nucleotides. As evidence suggests that 7-methylguanine is lost in a constant and predictable manner from the liver DNA of normal rats by chemical depurination reactions[5] the amounts of O^6-methylguanine were expressed as a ratio of the 7-methylguanine present in the same DNA to provide an estimate of the relative persistence of this O-methylated product. This ratio also provides a convenient internal standard to allow for any effects of toxicity that may lead to cell lysis, which would affect the loss of all DNA products in the same way.

Following DMN treatment at 5.5 mg kg^{-1}, the amounts of O^6-methylguanine and 7-methylguanine present in liver DNA of the control rats kept on an equivalent daily food intake were determined (Table 1). The results are similar to those obtained for weight-matched controls and lie within the expected range[6] both with regard to the amount of base formed and the ratio of O^6-methyl- to 7-methylguanine (compare with Figs 2 and 3). Data from these weight-matched controls have been used for comparison with AAF-pretreated animals. Results presented here are for AAF-pretreated rats with livers of normal appearance. This included the majority of animals (see ref. 7) and the remainder, which had sparsely nodular livers, are included in a separate study. Measurements of the exhalation of radioactively labelled CO_2 (ref. 8) indicated that the rate of metabolism of (^{14}C-methyl)-labelled DMN was similar in both control and AAF-pretreated rats. In agreement with previous reports for normal rats[8] the lower doses were metabolised more quickly but the process was nevertheless complete by 5 h in all cases. At this time the level of 7-methylguanine was similar in liver DNA from control and AAF-pretreated rats (Fig. 2*b*) and in both cases the amount formed was linearly related to dose. The amounts of O^6-methylguanine at 5 h were also dose-related but they were significantly lower for the AAF-pretreated rats, indicating that at all dosages the repair of this product was already well advanced (Fig. 2*a*): A comparison of the relative persistence of this base over a 48 h period further emphasised the differences observed between the two treatment conditions (Fig. 3). Thus, in control animals 5 h after DMN treatment at doses of 5.5 or 9 mg kg^{-1} this ratio of O^6-methyl- to 7-methylguanine approximates to the expected value of 0.115 for DMN[6]. At the highest dose there was a slight increase in this ratio over the next 20 h or so (Fig. 3*a*) and this rise can be accounted for by calculation of the expected loss of 7-methylguanine by chemical depurination, indicating that the amount of O^6-methylguanine had remained constant for this period. After this, the ratio decreases rapidly so that by the 48 h the value approaches that obtained for the lower doses at later times. This inhibitory effect is much less apparent at 5.5 mg kg^{-1} and was not detected at the 1 mg kg^{-1} dose. Also, at 1 mg kg^{-1} the ratio of methylated guanines is much lower, indicating that a greater relative proportion of the O^6-methylguanine initially present in DNA (see Figs 2*a* and 3*a*) was repaired than at the high doses. A similar effect is seen in AAF-pretreated rats but at each dose level the repair of O^6-methylguanine is enhanced, and at 9 mg kg^{-1} this

Table 1 Amounts of O^6-methylguanine and 7-methylguanine in liver DNA of control rats

DNA reaction product	Time after DMN treatment 5 h	 8 h	 24 h
7-Methylguanine*	412	378	275
O^6-Methylguanine*	39.8	36.9	14.4
O^6-Methyl/7-Methylguanine	0.097	0.098	0.053

Control rats, having received daily food intake equivalent to that of the AAF-pretreated animals, (see text) were treated with a single (i.p.) injection of DMN (5.5 mg kg^{-1}, 5 mCi mmol^{-1}). The livers of 3 rats were pooled for each time point, DNA was extracted by a modified phenol procedure[18] and hydrolysed in 0.1 M HCl (70 °C, 30 min). The authentic marker compounds 7-methylguanine, 3-methyladenine and O^6-methylguanine were added and the pH of the hydrolysate adjusted to 2.8. Purine bases were separated by chromatography[19] on columns of (1 × 100 cm) Sephadex G-10 eluted with 0.05 M ammonium formate—0.2% (w/w) sodium azide, pH 6.75 at a flow rate of 15–20 ml h^{-1}. The absorption at 260 nm of each fraction (4.5 ml) was determined and hence the amounts of adenine and guanine were calculated. The samples were dried and counted for radioactivity after addition of water (1.3 ml) and Triton-toluene phosphor (10 ml). These measurements were used to estimate the amounts of methylated purines.

* Amounts of alkylation products are given as μmol methyl per mol DNAP.

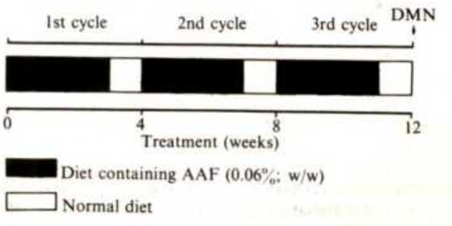

Fig. 1 Schematic representation of dietary regimen.

0028–0836/79/400403—02$01.00

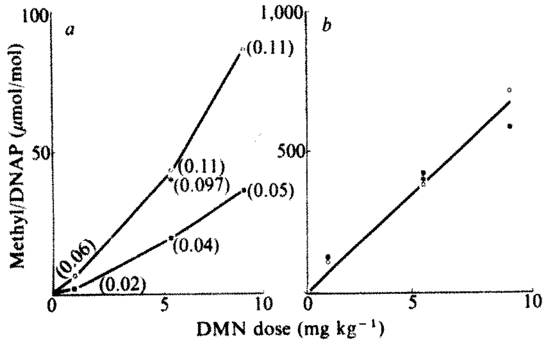

Fig. 2 Amounts of O^6-methylguanine (*a*) and 7-methylguanine (*b*) in the liver DNA of control (○) and AAF-pretreated (■) rats 5 h after administration of (^{14}C-methyl)-labelled DMN at 1, 5.5 and 9 mg kg^{-1} (specific activity 11 mCi mmol^{-1} for lowest dose and 5 mCi mmol^{-1} for higher two doses). Liver DNA was prepared and analysed as previously described (see Table 1 legend) and the 5 h values are taken from lines of best fit for results obtained for animals killed over a 48 h period. Lines of best fit were derived as follows: *a*, quadratic curves ($P < 0.05$ in each case) for AAF-pretreated rats; Gompertz curves were fitted for the control data; *b*, least square regression lines (coefficient of multiple correlation $R > 0.98$ in each case). The ratios of the amounts of O^6-methylguanine to 7-methylguanine are given in parentheses adjacent to the appropriate points. Values of these methyl purines taken from Table 1.

occurs to such an extent that there is no detectable inhibition of the repair process at all (Fig. 3*b*). Some recent reports have shown that chronic treatment with agents which produce O^6-methylguanine in DNA can also induce the repair of these lesions. This has been observed for rat liver DNA following chronic administration of DMN[9], in several organs of the rat following repeated injections of dimethylphenyltriazene[10] and for *Escherichia coli* following pretreatment with *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine[11].

In the AAF-pretreated animals the reason for the observed increase in the ratio of methylpurines at around 8 h (Fig. 3*b*) is obscure, but as metabolism of DMN is complete by the fifth hour no further increase in the amount of alkylation at the O^6-position of guanine could occur. Further, as reincorporation of this product is extremely unlikely[12], one possible explanation might be the induction of a specifically enhanced loss of 7-methylguanine over this short period: such a process has not yet been observed for rat liver DNA but this could be a side effect of the stimulation of the system for the repair of O^6-methylguanine in AAF-pretreated rats. For comparison, evidence for the repair of 7-methylguanine has been given in certain cases, for example in the DNA of the livers of mice[13] and of Syrian hamsters[14].

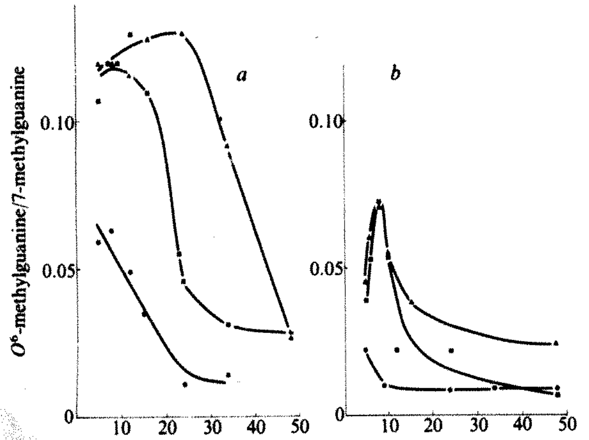

Fig. 3 Ratio of O^6-methyl- to 7-methylguanine in liver DNA in control (*a*) and AAF-penetrated (*b*) rats at various times after injection (i.p.) of (^{14}C-methyl)-labelled DMN at 9 mg kg^{-1} (▲), 5.5 mg kg^{-1} (■) and 1 mg kg^{-1} (●).

In conclusion, we have observed a dose-related repair of O^6-methylguanine in normal rats which, in agreement with previous work[6,15], is relatively more active at lower doses of DMN. Furthermore, a similar repair process is also present in AAF-pretreated rats, but here the repair of O^6-methylguanine is significantly enhanced at all doses used (Fig. 3). This effect is particularly evident at early times and when compared to controls there is a two- to threefold decrease in the ratio of these methylated guanines. It is interesting that a prolonged exposure to one carcinogen can induce the repair of lesions formed in DNA by another chemically unrelated carcinogen. Such an effect might be due to the induction of a general repair mechanism, possibly analogous to the induction of post-replication repair observed in AAF-treated Chinese hamster cells[16]. Alternatively, this might also be explained by the activation of a more specific repair system due to the formation of small amounts of an AAF-adduct at the O^6-position of guanine in DNA, particularly as such lesions have now been reported for the reaction of another aromatic amine, 1-naphthylamine, with DNA[17]. The formation of a lesion at a common site and its subsequent control by similar or closely related repair systems, which is implicit in the latter interpretation, may be especially relevant to the concept of mechanisms of carcinogenesis arising from agents belonging to different classes of chemical carcinogens.

We thank ICI Pharmaceuticals Division for the gift of the acetylaminofluorene diet and Dr M. K. Palmer and Mr R. Swindell for statistical treatment of the data. This work was supported by grants to the Paterson Laboratories from the MRC and the Cancer Research Campaign.

Corrigendum

In the letter 'Use of Panamanian sea urchins to test the molecular clock' by H. A. Lessios, *Nature* **280**, 599–601, line 4 in paragraph 6 should read '. . . in *Diameda* were 20 times higher than in *Echinometra*, we would . . .'

Erratum

In the letter 'Induction of sporulation in *Bacillus brevis* by peptide antibiotics' by H. Ristow *et al.*, *Nature* **280**, 165–166, in paragraph 2 line 6, for ". . . that of gramicidin D between t_1 and t_5.", read ". . . that of gramicidin D between t_1 and $t_{1.5}$." Also for the abscissa on the top of Fig. 1 "$t_1 \ldots t_7$", read "$t_0, t_1 \ldots t_6$".

matters arising

The cosmological evolution of QSOs

RECENTLY, Stewart and Hawkins[1] claimed that what is usually considered strong evidence for cosmological evolution of the number density of quasi-stellar objects (QSOs) is merely a statistical sampling effect. They find that the assumed evolution law, combined with the optical luminosity function of QSOs, predicts results that conflict with the observational data from which these two functions are derived. However, their result is due to several incorrect assumptions, and I suggest there is no such conflict for the largest homogeneous QSO sample available. Cosmological redshifts are assumed here throughout.

The proposal that the observed upper envelope of the points in the redshift–absolute optical luminosity plane is the result of statistical sampling[1] is not new. Schmidt[2] introduced the V/V_m test partly to remove this obvious selection effect, and a related method that also avoids the problem was proposed by Lynden-Bell[3]. In the V/V_m test, the number density evolution law is derived such that the selection effect is taken into account, and the luminosity function is then derived for a particular epoch (redshift) by applying this density law to the observed number densities at other redshifts represented in the sample. Note that the luminosity function cannot be derived independently of the assumed density evolution law. Stewart and Hawkins[1] claim that the upper envelope of the points in the log F_{2500}, log z plane is satisfactorily reproduced only if there is no significant density evolution, and that if the previously-derived evolution law and luminosity function are assumed there is a serious conflict between the predicted and observed envelopes (F_{2500} is the absolute luminosity, in W Hz^{-1}, at 2,500 Å rest wavelength, using a Hubble constant of 100 km s^{-1} Mpc^{-1}, and is related to Stewart and Hawkins absolute magnitude M_v by $\log F_{2500} = 13.32 - 0.4M_v$; z is the redshift). Apart from doubts concerning the use of the upper envelope as an efficient statistical indicator, I believe their calculations to be invalid for the following reasons: (1) if there is no density evolution, it is incorrect to adopt a luminosity function that was derived *via* the assumption of strong evolution; (2) if there is evolution, it is unjustifiable to extend the optical luminosity function to arbitrarily high values when there is clear evidence[3–6] for an upper limit; and (3) Stewart and Hawkins[1] have not taken radio selection effects into account properly. The probability that a radio-emitting QSO will find its way into a catalogue depends on its radio flux density, that is on its absolute radio luminosity and its redshift. This modifies their equation (8) for the number of QSOs detected as a function of z, by an amount that depends on the radio flux density limit. Those QSOs in Stewart and Hawkins[1] inhomogeneous sample (derived from ref. 7) that were originally found as radio sources come from surveys with quite different radio limits, which makes the modification of their equation (8) indeterminate.

Stewart and Hawkins'[1] result therefore seems to be based on erroneous assumptions, and as a check I have calculated the expected distribution of points in the log F_{2500}, log z plane for the largest homogeneous QSO sample published so far[5]. This contains 74 QSOs identified as 4C radio sources, with stringent radio and optical flux density limits. Redshifts, and therefore values of F_{2500}, are known for 71 of them[8]. It has been shown[5] that the luminosity function for the objects is adequately represented by:

$$dN \propto F_{500}^{-2.65} F_{2500}^{-1.08} V^{1.55} \times dF_{500} dF_{2500}\, dV \qquad (1)$$

where F_{500} is the absolute radio luminosity[2] and $V(z)$ is the co-moving volume out to redshift z, using a deceleration parameter $q_0 = 1$. Over the redshift interval represented in the sample, the $V^{1.55}$ density evolution law is virtually indistinguishable from that used by Schmidt[9] and by Stewart and Hawkins[1]. It was shown[3–6] that the optical luminosity function steepens significantly near 10^{24} W Hz^{-1} (Stewart and Hawkins[1] assume that the function can be extrapolated to luminosities ~100 times this value). Using equation (1) with a cutoff at 10^{24} W Hz^{-1}, it is straightforward to derive the expected distribution of points in the log F_{2500}, log z plane (Fig. 1). The agreement is clearly satisfactory, except in the highest luminosity interval which probably indicates that the effective cutoff is somewhere in the interval log $F_{2500} = 23.6$–24.0 (ref. 5). Any remaining inconsistencies in Fig. 1 are trivial in the present context; they probably arise through neglect of possible interdependences of the functions in equation (1).

The agreement between the predictions and observations, shown in Fig. 1, should not be surprising, because the density evolution law and luminosity function used in the calculations were derived from the observations, but it entirely removes the basis for Stewart and Hawkins' dismissal of the substantial evidence for number density evolution derived from

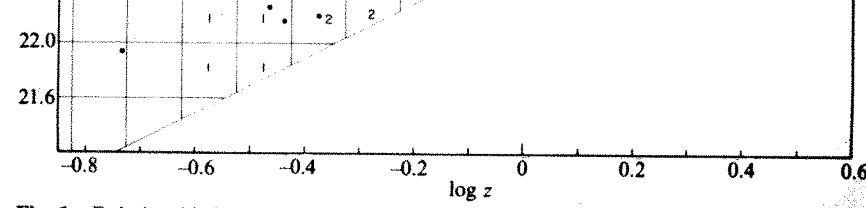

Fig. 1 Relationship between absolute optical luminosity (F_{2500}) and redshift (z) for QSOs in the homogeneous sample (from ref. 5). The predicted distribution is shown as the numbers of QSOs in cells 0.4 wide in logF_{2500} and 0.1 wide in log z, or in the smaller areas if the cell is crossed by the sloping line, which is the limiting apparent magnitude of the sample. The predictions assume an upper limit of 10^{24} W Hz^{-1} in the luminosity function[3–6]. Where no predicted number is given, it is <0.5 per cell. The total numbers of QSOs predicted in the intervals log $z = -0.625$ to -0.725, -0.725 to -0.825, and < -0.825 are 2.0, 1.1 and 1.1 respectively. The points show the observed distribution.

STEWART AND HAWKINS REPLY—it seems clear that there is no essential disagreement between Wills' response and the primary result of our original paper[1]; that if one takes the evolutionary law and luminosity function for quasars widely found in the literature and models the (L, z) plot one finds a disagreement with the observations, whether one uses the large list of Burbidge *et al.*[2] or the complete sample of Wills and Lynds[3], in the sense that there is a shortage of very luminous objects. The question now arises as to why this disagreement with the observations exists. Wills accepts that the evolution law and luminosity function are correct and solves the problem by involving a 'cutoff' in the luminosity of quasars, that is by saying that that for some reason a quasar cannot be more luminous than 10^{24} W Hz^{-1} at 2,500 Å.

An attempt was made[1] to discuss the distribution in the (L, z) plot without invoking a cutoff by relaxing some of the assumptions, in particular by allowing the evolution rate to be an adjustable parameter and maintaining the luminosity function unchanged, although allowing rather large error bars. Wills is not strictly correct in saying that the two cannot be distinguished as it is clear[1] that the slope of the upper envelope in the (L, z) diagram at low redshift is determined by the index of the luminosity function alone. The result[1] was that the distribution of quasars in (L, z) could be accounted for very naturally with low or zero evolution, and in particular the absence of very luminous objects was shown to be a simple geometrical effect, thus removing the need for a cutoff in quasar luminosity.

It is obvious that if one regards the results of previous measurements of quasar evolution as being beyond reproach one is forced to introduce a luminosity cutoff and all Wills' results follow. However, as this widely held position is based on the results of a single test—the V/V_m test—it seems to us that one ought to look more closely at this and ask if it is really giving the right result. This question is treated more fully in another paper[4].

If one insists that the V/V_m test is giving the right answer then Wills is quite right and a cutoff, evolution and so on are all required. However, given the results of ref. 1 it seems desirable to re-examine the V/V_m test, as it may be possible to abandon two *ad hoc* hypotheses, that is, quasar evolution and luminosity cutoff, if its results turn out to be incorrect.

Mixed ligand chelate therapy for plutonium and cadmium poisoning

I HAVE accumulated information leading me to doubt the veracity of results published in a report[1] and a reply[2] of which I was the co-author. I have repeated the experiments personally, and thus far find that in the stated conditions[1] I do not confirm these results. The experiments reported for cadmium poisoned mice, for example, did not, contrary to data provided me, include experimental controls for the individual chelants at the stated doses. Further, treatment was given 5 min post-Cd and not 1 h, as stated. At the latter time no survival is observed. Neither can I confirm the results described for plutonium decorporation by diethylenetriaminepentracetic acid/salicyclic acid (DTPA/SA). In fact, from potentiometric titration studies which I now carry out as a screening method for the identification of mixed ligand chelate (MLC) systems potentially useful for biological applications, I find that the DTPA/SA systems do not form significant levels of MLCs with a cation similar to Pu(IV), namely Th(IV). However, DTPA and catechol or Tiron do form MLCs but that with EDTA instead of DTPA is superior.

I believe that MLC phenomena constitute a potentially superior approach for the treatment of metal poisons. However, the extent to which this is realised will be determined by the results of my own experiments and those of others. In the meantime, I am forced to conclude that the previously published results[1] are invalid.

Mixed ligand chelation therapy

SCHUBERT AND DERR[1] have reported that mixed ligand chelates (MLCs) of DTPA and salicylic acid (SA) markedly enhance the clearance of ^{239}Pu from mice. We have examined this procedure in rats (196–224-d-old females, HMT strain, from the MRC Radiobiology Unit, Harwell) using similar injection procedures and similar analytical procedures. Analysis for ^{239}Pu in excreta from animals caged singly, six animals per group, as well as the kidneys, livers, spleens and carcasses, showed that there was no significant difference between either the DTPA group or the DTPA/SA group.

We have also investigated the extraction of ^{239}Pu into heptane and found no evidence that Pu(EDTA)SA is lipophilic. Unfortunately the extraction procedure was not described; however, our extraction procedure has been used routinely to demonstrate the interaction of ^{239}Pu^{4+} with phospholipids[2].

Furthermore, we have found that intravenously injected NaSA (2.0 mmol per kg) is acutely lethal to rats and it is known that 10–30 g of NaSA is lethal to man[3]; the injection procedure of Schubert and Derr would necessitate intravenous administration of 22 g of NaSA to man every 3 d.

After completing our work we learnt that Schubert had withdrawn some of his claims, but we still view his optimism for MLC therapy with caution. For MLC therapy to be successful it will require administration of a chelating agent sufficiently lipophilic to offset the hydrophilicity of the Pu DTPA complex. There is no reason to believe that such diverse species enter cells in synchrony; in addition, we might wonder if serum citrate could not be part of an MLC with Pu and DTPA. It is more likely that synergistic chelation therapy[4] will contribute more to toxic metal decorporation than MLC therapy.

Lowland Maya radiocarbon dates and the classic Maya collapse

SIDRYS AND BERGER[1] assert that "the demise of the stela cult and the breakdown of elite culture seem to have coincided" among the Late Classic Maya population of the Southern Lowlands. Their evidence leans heavily on a comparison of frequency distribution graphs for long count-dated Maya monuments and radiocarbon-dated organic materials. The authors claim that the graphs are "remarkably similar", and that their resemblance "helps to establish the reliability of the ^{14}C frequency-distribution bar-graph method".

We feel that the radiocarbon data presented by Sidrys and Berger show such a bias in sampling that the conclusions they draw are unreliable and misleading. Of the 96 radiocarbon dates plotted for the 'elite contexts' (in contrast to 415 monument dates) 66 dates are from the site of Tikal—no other single site is represented by more than 5 dates. Since the authors are attempting to analyse a demographic phenomenon that took place over thousands of square kilometres and involved many population centres, we suggest that selecting nearly 70% of the samples from one site dangerously disregards basic tenets of sampling theory. To demonstrate the effect that such an extreme bias in the radiocarbon data can have on the interpretation made by the authors, we have replotted their frequency-distribution graph for elite contexts, specifically excluding the dates from Tikal. The dates from all of the other 26 sites and artefacts that are listed in their Table 1 have been left unchanged. For comparison we have also reproduced the authors' original graph, which includes the Tikal data.

The replotted data (Fig. 1*b*) fail to support any significant 'breakdown of elite culture' during the eighth to eleventh centuries AD It is not our intention to question whether or not a breakdown actually took place. Our point is that such a drastic difference in interpretation, based solely on the presence or absence of data from a single site, renders spurious Sidrys and Berger's argument that a connection between the demise of the stela cult and the breakdown of elite culture is supported by a similarity between the frequency distribution of monument dates and elite context radiocarbon dates.

While we endorse the trend towards increasing quantification of archaeological data, particularly for the purpose of hypothesis testing, we emphasise that studies involving demography must take into account the need for representative sampling of available sites and contexts.

R. GARBER
Section of Botany, Genetics and Development,
Cornell University,
Ithaca, New York 14853

1. Sidrys, R. & Berger, R. *Nature* **277**, 269–274 (1979).

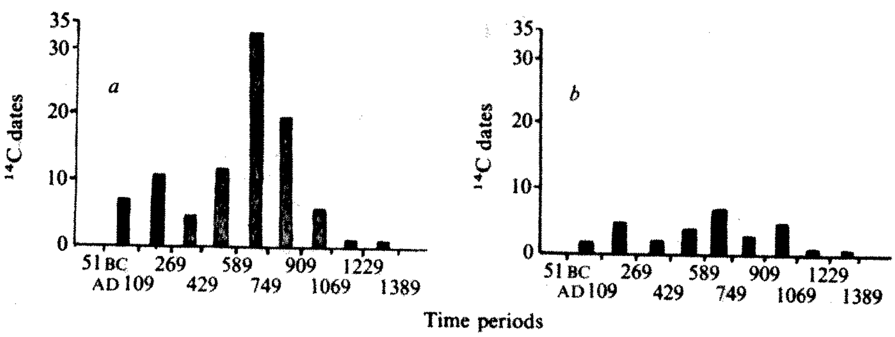

Fig. 1 *a*, Radiocarbon dates from elite contexts in the Southern Lowlands per time period, including dates from Tikal. *b*, The same data as in *a*, but excluding the dates from Tikal.

SIDRYS AND BERGER REPLY—Our study did take into account the need for representative sampling of available sites. The high proportion of Tikal cases in our ^{14}C graph of elite contexts simply reflects the abnormally large number of aristocrats, priests and administrators present at Tikal—a factor that Sterns, Loria and Garber overlook. Population estimates for Classic Maya centres are difficult to obtain and their reliability may be off by at least a factor of two. Nonetheless, those studying the Mayan culture are in general agreement that Classic period Tikal was the largest population centre, with about 50,000 inhabitants[1] (some estimates are as high as 80,000). The number of Tikal elite has been estimated[2] to be 1,000. In contrast the average population of the other 18 sites used in our Fig. 3*a*, according to our own 'guestimates' based on house mounds and size of ceremonial area, as well as the little published demographic data available, falls somewhere between 3,000 and 9,000.

Our sampling procedure thus mirrors Classic Maya cultural reality—the overwhelming economic and political dominance of the capital city of Tikal. Viewed from this perspective, the above graph by Sterns, Loria, and Garber that eliminates Tikal from the total elite sample is the equivalent of a demographic study of the state of New York that does not include New York City. At the same time, we do emphatically reiterate that more Maya ^{14}C dates from commoner contexts are urgently needed to resolve the issue of the Classic Maya collapse.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Ca^{2+} and photoreceptor adaptation

FLAMING AND BROWN[1] seem to have missed the point of our earlier work on the effects of altered extracellular Ca^{2+} on rod photoreceptor responses[2], and they give a misleading impression of the possible role

0028–0836/79/400407—02$01.00

of Ca^{2+} in mediating sensitivity changes that occur in rods during light and dark adaptation. We found that altering extracellular Ca^{2+} alters the amplitude of rod responses dramatically in the dark-adapted retina, but that the sensitivity of the rod (determined principally by σ, the position of the V–log I curve on the intensity axis) is virtually unchanged. As both amplitude and sensitivity vary substantially during light and dark adaptation, we concluded that changes in cytosol Ca^{2+} levels could not explain adaptation in photoreceptors. For example, we showed (Fig. 5 of ref. 2) that raising extracellular Ca^{2+} from 1.8 to 3.2 mM reduced V_{max} of the rod response by about 38%, but that in these conditions of high extracellular Ca^{2+} a significant shift in the position of the V–log I curve on the intensity axis could not be detected. There is, of course, some uncertainty in intracellular recording measurements, and therefore it is possible that within our error range (±0.2 log units) some small changes did occur. However, such changes are insignificant compared to the changes that occur when a rod is adapted by a light that reduces its maximum amplitude response by the same amount that 3.2 mM Ca^{2+} reduces V_{max}. For example, Fig. 6 of ref. 2 showed that an adapting light which reduced the rod response amplitude by 35% caused a shift of the V–log I curve along the intensity axis by at least 1.6 log units. In other words, in comparable conditions of V_{max} reduction, light causes a 65-fold change in rod sensitivity, but raised $[Ca^{2+}]_o$ changes sensitivity no more than 2–3 times. This was the main point on which our conclusion was based.

Flaming and Brown now report that if they raise or lower extracellular Ca^{2+} they can detect small changes in the position of the rod V–log I curve on the intensity axis and they suggest, therefore, that it is possible that alterations in cytosol Ca^{2+} levels can account for sensitivity changes in photoreceptors during light and dark adaptation. They report that raising extracellular Ca^{2+} from 1.8 to 6 mM causes the V–log I curve of the dark-adapted rod to shift by an average of 0.26 log units. In their Fig. 1 (ref. 1), they show that such an increase in $[Ca^{2+}]_o$ decreases a rod V_{max} by about 45%. If light is used to reduce V_{max} by this amount, however, the position of the V–log I curve alters not by 0.2–0.3 log units, but by about 2 log units. Thus, their data are in close agreement with our findings, and they support our conclusion that, "although cytosol Ca^{2+} concentrations are capable of regulating the membrane potential of the cell and its response amplitude, they affect only to a minor extent the sensitivity of the receptor cell in the dark-adapted or partially light-adapted state" (ref. 2).

Bastian and Fain[3] have recently carried out experiments similar to those of Flaming and Brown and ourselves. They found, in agreement with Flaming and Brown, that small shifts in the V–log I curve can be detected when extracellular Ca^{2+} is altered sufficiently, but their results also show clearly that the effects of increases in extracellular Ca^{2+} do not at all resemble the effects of background light on either rod sensitivity or response waveform. We may not have observed the small shifts of the V–log I curve in low and high Ca^{2+} because of the reasons outlined by Flaming and Brown. However, our failure to observe these changes in no way alters our conclusion that cytosol Ca^{2+} levels cannot be the major determinant of rod sensitivity during light and dark adaptation. Indeed, all three studies discussed here provide evidence in favour of this conclusion.

3. Bastian, B. L. & Fain, G. L. *J. Physiol., Lond.* (in the press).

FLAMING AND BROWN REPLY—in agreement with all other authors, Lipton *et al.*[1] found that increased extracellular Ca^{2+} markedly reduced V_{max}. Their new finding was that raised or lowered extracellular Ca^{2+} concentration exerted no detectable effect upon σ, the stimulus intensity eliciting a response of half the maximum amplitude, although σ was altered significantly by adaptation. They stated that "The experiments do indicate that in a partially light-adapted rod the membrane potential and cytosol Ca^{2+} levels do not regulate the major determinant of sensitivity (σ), ...". We recently[2] showed that when external Ca^{2+} was varied from 0.3 to 6.0 mM, σ shifted to higher light intensities by about 0.75 log units. Both increases and decreases of Ca^{2+} concentration from the control level of 1.8 mM elicited consistent σ shifts that were detected readily. Our conclusions were: "Thus, our results indicate that alteration of $[Ca^{2+}]_o$ can control the value of σ in the V–log I curve of toad rods. These results are consistent with a role for $[Ca^{2+}]_i$ in the control of sensitivity in vertebrate photoreceptors. Hence, changes of $[Ca^{2+}]_i$ may partially control the changes of sensitivity that occur during light and dark adaptation". Our conclusion that $[Ca^{2+}]_o$ can exert a controlling effect on σ differs from the conclusion of Lipton *et al.*[1] in an important respect, and we note that they now accept the validity of our findings on this point.

One remaining question concerns the degree to which $[Ca^{2+}]_i$ can control the value of σ. Taken at face value, our results suggest that $[Ca^{2+}]_i$ could only control a small portion of the adaptive σ shifts. However, we demonstrated that our Ca^{2+}-induced σ shifts depended on several improvements in experimental conditions, and one critical factor was a more normal perfusate containing 15 mM of bicarbonate, which was used for buffering[2] instead of HEPES[1]. It thus seems that the induction of σ shifts by altering $[Ca^{2+}]_o$ is more sensitive to subtle chemical factors in the perfusate than are the effects of $[Ca^{2+}]_o$ on V_{max}. This suggests that it is especially important to compare σ shifts induced by adaptation, and by alteration of $[Ca^{2+}]_o$, in physiologically normal experimental conditions. Although we have made some improvements in that direction, we are not convinced of having attained the requisite success, which may be very difficult with an isolated and perfused preparation. Also, even in a completely normal preparation, an elevated $[Ca^{2+}]_o$ may not adequately mimic the effects of increased $[Ca^{2+}]_i$. For reasons such as these, we deliberately drew no conclusion concerning the degree to which $[Ca^{2+}]_i$ may normally control adaptive σ shifts. Although Lipton *et al.*[1] failed to detect any of the controlling effect of $[Ca^{2+}]_o$ on the value of σ, their letter indicates great confidence concerning the quantitative control of σ by $[Ca^{2+}]_i$. As premature conclusions based on inadequate evidence can be 'misleading', it seems advisable to await more definitive evidence on this issue.

ICE AGES

M

: Solving the Mystery
Professor John Imbrie and
Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what caus
ice ages to occur. The theory that was confirm
explained along with many others in I
Milankovitch, or astronomical theory w
glaciation as the result of three regular
makes as it travels around the sun: cha
earth's orbit, "wobble" of the earth's axi
the earth's axis.

"ICE AGES is fascinating in its scientific i
detective story. I recommend it to all." Dr.
Laureate.

LIFE IS A SCIENCE

MEDICINE AND PHARMACOLOGY

The Thyroid

Physiology and Treatment of Disease

JEROME M. HERSHMAN, *VA Wadsworth Hospital Center, Los Angeles, USA*
GEORGE A. BRAY, *UCLA School of Medicine, Los Angeles, USA*

International Encyclopaedia of Pharmacology and Therapeutics, Section 101

The volume covers basic thyroid physiology and treatment of thyroid disease. The emphasis of the book is on a comprehensive, modern, pharmacological approach to the treatment of thyroid disorders. The extensive reference list contains over 3700 entries.

ISBN 0 08 017685 2 H **US$100.00 £50.00**
640pp. September 1979

Disasters: Hospital Planning

A Manual for Doctors, Nurses and Administrators
P.E.A. SAVAGE
Queen Mary's Hospital, Sidcup, Kent, England

This volume provides a 'blueprint' for hospitals developing their own detailed plan to manage a large number of casualties following a major accident or disaster.
It discusses the main areas requiring pre-planning and includes a detailed disaster manual that can easily be adapted to suit the circumstances of individual hospitals.

ISBN 0 08 024914 0 H **US$20.00 £10.00**

A Handbook on Medical Biotelemetry and Radiotracking

Proceedings of the First International Conference on Telemetry and Radiotracking in Biology and Medicine

CHARLES J. AMLANER & DAVID W. MACDONALD, *University of Oxford, England*

'A Handbook on Medical Biotelemetry' presents a wealth of new material on both techniques and results. Almost every paper presents new techniques and modifications in the construction and use of equipment, and in the interpretation of data. Its multidisciplinary nature bridges the gap between the technologist and biologist, and makes it suitable for the medical doctor, the behaviourist and the engineer working in telemetry.

ISBN 0 08 024928 0 H **US$88.00 £40.00** (approx)
800pp. December 1979

NEUROSCIENCES

Biochemistry of Brain

SUDHIR KUMAR
Director of Perinatal Laboratory, Christ Hospital, Oak Lawn, USA

The major goal of the book is to provide a single source of information on the various aspects of brain biochemistry. Each chapter reviews a particular topic in complete detail, giving information on the available knowledge to date, methods of study and results, and author's suggestions on possible guidelines for further work.
It will be useful not only to neuroscientists, biochemists, nutritionists and physiologists, but will also be of value to medical students and graduate and post-graduate students interested in the study of brain biochemistry.

ISBN 0 08 021345 6 H **US$100.00 £50.00**
634pp. November 1979

The Neostriatum

Proceedings of a Workshop sponsored by the European Brain and Behaviour Society, Denmark, 17–19 April 1979

IVAN DIVAC, *University of Copenhagen, Denmark*
R. GUNILLA E.OBERG, *University of Aarhus, Denmark*

The edited papers from this Workshop provide a comprehensive review of research on the neostriatum and current concepts about neostriatal function.
The multidisciplinary nature of this work will make it of considerable interest to specialists in all branches of the neurosciences as well as psychiatrists and psychologists.

ISBN 0 08 023174 8 H **US$40.00 £20.00**
334pp. October 1979

New Books from Pergamon

Biophysical Aspects of Cerebral Circulation

YU. E. MOSKALENKO
I.M. Sechenov Institute of Academy of Sciences of the USSR

This book summarizes current knowledge concerning the preservation of cerebral oxygen within adequate limits, in the face of variable demand and supply, by the regulatory mechanisms of the cerebro-vascular control system.

ISBN 0 08 022672 8 H **US$40.00 £18.00**

BIOLOGY AND BIOCHEMISTRY

Cyclic Phenomena in Marine Plants and Animals

Proceedings of the 13th European Marine Biology Symposium, Isle of Man, Sept–Oct 1978

E. NAYLOR and R.G. HARTNOLL
Department of Marine Biology, University of Liverpool, Port Erin, Isle of Man

This volume contains 54 edited papers from laboratories and institutions in Europe and North America giving the latest results of research on cyclical aspects of the ecology, behaviour and physiology of marine plants and animals. It will be of interest to all marine biologists and to all scientists concerned with the study of rhythmic biological processes.

ISBN 0 08 023217 5 H **US$50.00 £25.00**
502pp. September 1979

An Introduction to Feeding Farm Livestock, 2nd Edition

R.H. NELSON

This is a second edition of an extremely popular and authoritative student textbook. It gives an explanation of the science underlying the feeding of farm livestock and includes a step-by-step approach to a scientific compilation of rations. The text assumes only a basic knowledge of nutrition and feeding practices on the farm.

ISBN 0 08 023757 6 H **US$20.00 £10.00**
ISBN 0 08 023756 8 F **US$ 8.00 £ 4.00**
162pp. September 1979

Recombinant DNA and Genetic Experimentation

An international conference covering the science and public policy aspects of recombinant DNA jointly sponsored by the Committee on Genetic Experimentation and the Royal Society of London, and held at Wye, England, 1–4 April 1979

J. MORGAN & W.J. WHELAN

This book provides the first objective, informative and up-to-date summary of this controversial subject, written by scientists active in the field.

ISBN 0 08 024427 0 H **US$50.00 £22.50**
450pp. November 1979

Plankton and Productivity in the Oceans, 2nd Edition

Volume 1 – Phytoplankton
J.E.G. RAYMONT
University of Southampton
With contributions from J.D.B. BURTON and K. DYER

This is a new edition of an established student textbook, now produced in two volumes. The book presents a comprehensive review of the marine plankton and includes such varied aspects of plankton study as the basic structure of organisms, the geographical distribution of species in the world's oceans, vertical distribution and important phyto-plankton and zoo-plankton interrelationships, especially in relation to productivity. Considerable attention has been paid to the physiology and biochemistry of planktonic organisms.

ISBN 0 08 021552 1 H **US$50.00 £25.00** (approx.)

Topics in Carbon-13 NMR Spectroscopy Vol. 3

edited by **G.C. Levy**, *The Florida State University, Tallahassee*

A chronicle of recent advances in Carbon-13 NMR theory and methodology covering a wide range of interests, from molecular biology to polymer physics, from molecular dynamics to organic structure analysis. It bridges the gap between current research literature and available 13C NMR texts and reviews. (Series: *Topics in Carbon-13 NMR Spectroscopy)*

September 1979 410 pages
0471 02873 8 $46.50/£21.40

Applied Infrared Spectroscopy:
Fundamentals, Techniques, and Analytical Problem-Solving

by **A.L. Smith**, *Dow Corning Corporation*

This presents an overview of applications, a critical evaluation of current techniques for sampling and for obtaining spectra, and an extensive guide to the literature, both spectra and papers. It covers everything from the preparation of almost any kind of sample and the optimization of the controls on an infrared spectrometer, to the identification and measurement of pollutants at the parts per million level. *(Chemical Analysis Series Vol. 54)*

September 1979 336 pages
0471 04378 8 $33.50/£15.20

The Plastically Crystalline State:
Orientationally Disordered Crystals

edited by **J.N. Sherwood**, *Department of Pure and Applied Chemistry, University of Strathclyde*

This contributed volume presents a detailed review of work on these materials which has been carried out over the past twenty years. These high temperature cubic phases of solids comprised of globular molecules are formed from normal crystals by one or more phase transformations. They are highly plastic and occasionally can be observed to flow merely under the influence of gravity alone, as a result of which this class of compounds are commonly referred to as plastic crystals.
This volume concentrates primarily on the scattering effects produced by such crystals in various types of spectroscopic investigation.

April 1979 410 pages
0471 99715 3 $48.00/£19.50

How to Find Chemical Information:
A Guide for Practicing Chemists, Teachers, and Students

by **R.E. Maizell**, *Olin Corporation*

A practical approach to the focal issues of chemical information sources, showing how to locate efficiently, use, and in some cases evaluate chemical data. It presents the most important and enduring classical tools, the more significant newer tools, and the underlying methods, principles, and keys needed to cope with the constantly changing array of chemical information sources and tools.

September 1979 258 pages
0471 56531 8 $24.00/£11.00

Ocean Science

by **K. Stowe**, *California Polytechnic State University*

A general survey of ocean sciences which requires little scientific or technical background. It includes a history of oceanography; sections on geology, chemistry, and biology; the ocean's interaction with other parts of the environment; and a section of marine resources. Underlying causes of phenomena are emphasized and review questions follow each chapter.

August 1979 624 pages
0471 04261 7 $21.00/£9.50

Remote Sensing and Image Interpretation

by **T.M. Lillesand**, *University of Minnesota*,
and **R.W. Kiefer**, *University of Wisconsin, Madison*

A clear, concise, thorough, and objective synthesis of the subject, providing a broad introduction to electromagnetic remote sensing of earth resources. It presents basic principles and concentrates on photographic remote sensing techniques, treating tools of photography and introducing the airphoto interpretation process. It also deals with principles of acquiring and interpreting data collected by non-photographic sensors, discussing thermal scanners, multispectral scanners, and radar systems.

September 1979 624 pages
0471 02609 3 $27.00/£12.50

Properties and Management of Forest Soils

by **W.L. Pritchett**, *University of Florida*

The fundamentals of forest soils are presented here with particular reference to the application of basic principles of soil science to silviculture. The book describes the forest floor as the centre of biological activity and the storehouse of cycling nutrients, and examines the influence of the forest cover on the biological, chemical and physical properties of soils.

August 1979 512 pages
0471 03718 4 $24.75/£9.50

Introduction to Forest Biology

by **H.W. Hocker Jr.**, *University of New Hampshire*

A comprehensive and well-illustrated introduction to the concepts required as background for silviculture. It reviews such areas as soils, physiology, ecology, genetics, and forest influences and covers forest stand structure and growth, tree reproduction, factors that influence tree growth (atmosphere, soil, biota),and the effects trees have upon the immediate environment.

Deficiencies in the Green Revolution

D.L. Gunn

Beyond the Green Revolution: The Ecology and Politics of Global Agricultural Development. By K.A. Dahlberg. Pp. 256. (Plenum: New York and London, 1979.) £11.30.

MILLIONS of people are undernourished or even starving, especially in the tropics. Yields of basic foods, generally cereals, are often poor. The Rockefeller Foundation therefore sent a team led by N.E. Borlaug into Mexico to breed more productive varieties of wheat for use in the tropics. He was very successful and the new seed has much increased crops in many places, for example enabling Pakistan to change from importing to exporting wheat. The technique has since been followed with other cereals. This has been called the Green Revolution, the great increase in food using scientific means.

Everyone involved in agriculture knows, however, that large increases in crop yields cannot be achieved and sustained by simply substituting the new seed for the old. More plant food (artificial fertiliser), extra water, herbicides and insecticides may all be required. Thus, full success with new wheat strains requires money to be invested in these extra inputs and also new knowledge and skills. The vast numbers of struggling subsistence farmers — about whom Dahlberg is mainly concerned — are too poor to use the new wheat.

Kenneth A. Dahlberg, a social scientist, has come across these well-known facts and in this book, emphasising the deficiencies of the Green Revolution, he pleads for re-assessment of situations by "contextual analysis". For biologists there is nothing new in seeking to examine a situation as a whole before suggesting how to alter it; that is similar to examining a problem in its context. Dahlberg explores a very wide context. In three chapters entitled "Ecology of Theories", "Historical Seedbeds" and "Jack and the Beanstalk", he outlines the influence of European tradition, of climate on the kind of ecological theory produced, and of trade on economnic thought; the resulting ideas have little relevance to subsistence agriculture in the tropics. Contextual analysis is put forward for examining situations instead of proposing actions merely because they would be effective in a temperate climate.

The remaining chapters are headed "The Momentum of Structures", "Institutions and Current Policies"; "New Approaches to the Future"; "Agricultural Strategies and Policies for the Future"; and "Hindsight, Insight and Foresight".

The author is critical and censorious about the European colonial powers, especially the British, to whom he imputes selfish national motives. Actually many agricultural officers and district commissioners were more concerned about the welfare of the local people than about the trade interests of the mother country. They discovered most of the complications that Dahlberg expounds and their long and devoted service did help the peasants in many places; but they did not solve the problem of financing innovation — not merely a matter of providing the money. The British Government set up the College of Tropical Agriculture in Trinidad, through which intending agricultural officers passed. They were trained to understand both agricultural and sociological complications, either in the College or on the job.

Amongst the many criticisms of European influence, there is one commendation implied in the stated failure of North American charities "to draw upon the extensive experience of Europeans in semi-tropical research, extension and education"; but why *semi*-tropical?

There is of course no doubt that European influence in tropical countries has disrupted old ways, often regretably; but should the destruction of the Ashanti, the Zulu and the Matabele bloodthirsty modes of life be regarded as good or bad? Those tribes certainly restricted the population growth of others; and the Zulus left much of the Transvaal empty and open to the incoming Boers.

Dahlberg does mention the explosive increase in human population as the most important change now taking place, but he merely asks "Can you condemn millions to starvation by not making every effort to increase agricultural production, especially if there is any chance that some solution to the population problem can be found in coming decades?" He hopes for options other than "lifeboat ethics".

It is this population increase in the less developed countries — and only there — that creates the problem. There would be little difficulty today in feeding the world population of my youth, two thousand millions, but where will it end? Well-intentioned Christian missions, the pax Britannica, medico-sanitary innovations by Europeans in the tropics, saving the children, and famine relief in general, have been responsible for creating the problem and destroying long-term stability. The problem is not how to produce enough food for everyone at present, although that is how it is usually stated. The problem is how those who cannot produce enough for themselves are to pay others to produce it for them. It is a problem of poverty. What can the poor do or produce that the rest of the world will be willing to buy? Industrial development, rejected by Dahlberg, is one partial solution, although it increases the problem of urban poverty, constantly fed from a profligately breeding rural population. Producing enough food for everyone now, even if it has to be given away to the poor, merely postpones greater starvation. There is no remedy in the long term for food shortages and for losses of irreplaceable resources without stopping the growth of population.

The author cites the resistance of the developing countries at the 1972 Stockholm Conference to any interference by environmentalists (regarding, for example, use of pesticides) and interprets it as misplaced confidence by elitists in Western conceptions of development; it seemed to me to arise more from preference for preserving the lives of their people rather than their eagles. That was certainly expressed at the Royal Society Discussion on Control of Migrant Pests in 1977. He also refers to vested interests in the debate over pesticides, without mentioning specifically the large and lucrative anti-pesticide industry, which was prominent at Stockholm. He writes that the World Food Conference and other such planning meetings propose solutions to food supply problems that are anti-ecological, evidently using the word ecological in the modern propaganda sense rather than as it is used in biology. Indeed, his acceptance of alarmist propaganda makes one wonder how much reliance is to be placed in statements in less familiar spheres.

This book is well-intentioned, sometimes interesting, sometimes dreary, sometimes misleading, sometimes muddled — "What is needed are a series of policies...", and sometimes obscure —

"information forwarded by life...". A more objective and perhaps humble analysis of past searching for improvement, less censorious but critical where something could be learnt, would have been more acceptable. It would have been illuminating to have a comparison of progress in Africa with that in South America. The book may have something for social scientists; it has nothing for agriculturalists.

There are nine pages of references and an index of 18 pages. In neither is Borlaug's name mentioned. ☐

D.L. Gunn, now retired, has been Director of the International Red Locust Control Service, Northern Rhodesia, Director of the Tea Research Institute, Ceylon, and Adviser to the Secretary of the Agricultural Research Council, London, UK.

African mammal palaeontology

Evolution of African Mammals. Edited by V. J. Maglio and H. B. S. Cooke. Pp.641. (Harvard University Press: London and Cambridge, Massachusetts, 1978.) £42; $60.

POTENTIAL READERS should clearly appreciate that this volume represents the first effort to put together in one book complete overviews of all African mammal groups. I want to congratulate the editors, Maglio and Cooke, for providing the impetus which led each of many specialists to articulate for the first time the entire known African story of his group. It should be stressed that much of what is presented in this volume, both in terms of materials and discussion, is quite new.

Authoritative introductions on present-day mammals of Africa (Bigalke) and the geological development of the physical African setting (Cooke) set the stage for 27 systematic chapters. These vary greatly, and appropriately, in length and depth of treatment. There can be little doubt but that the 95 pages by Howell represent the most complete and useful treatment available of the African evolution of the family of man, the Hominidae. The paper combines some provocative interpretations with admirably balanced consideration not only of the different African fossil sources, but also of the legion of opinions expressed on and around hominid evolution.

Several other larger contributions are particularly impressive and comprehensive, notably those on Proboscidea (Coppens, Maglio, Madden and Beden), Bovidae (Gentry), Suidae and Tayassuidae (Cooke and Wilkinson) and Equidae (Churcher and Richardson). There are also substantial chapters on mesozoic mammals (Crompton and Jenkins), Insectivora and Chiroptera (Butler), Rodentia and Lagomorpha (Lavocat), prosimian primates (Walker), Cercopithecidae and Parapithecidae (Simons and Delson), cenozoic apes (Simons, Andrews and Pilbeam), *Ramapithecus* (Simons and Pilbeam), Carnivora (Savage), Pholidota and Tubulidentata (Patterson), Hyracoidea (Meyer), Deinotherioidea and Barytherioidea (Harris), Rhinocerotidae (Hooijer), Anthracotheriidae (Black), Hippopotamidae (Coryndon), Cervidae and Palaeomerycidae (Hamilton), Giraffidae (Churcher), Sirenia (Domning) and Cetacea (Barnes and Mitchell).

Some shorter papers on lesser known groups add fascination by the strangeness of the beasts they describe: Embrithopoda (Tanner), Moeritherioidea (Coppens and Beden), Chalicotheriidae (Butler), Tragulidae and Camelidae (Gentry). Maglio's summary chapter on faunal turnover and succession, distribution and endemism, will probably be extensively used in future zoogeographic and evolutionary studies.

Much as each of the 30 fine contributions in this volume deserves individual comment, in a review of this length I will have to be content with expressing some overall impressions. The chronology, geography and stratigraphy of fossil finds are exceptionally completely and lucidly covered in numerous tables, maps and discussions. The histories of early fossil finds and conclusions are full of interest, and occasional humour. For example, in Harris' work on deinotheres we are told: "Buckland's (1835) quaint portrait of a mammal anchored to a river bank by its tusks while it slept preceded the discovery of deinothere hind limbs". Illustrations pinpointing precisely salient morphological differences or primitive-to-advanced series, like those provided by Gentry (p544), Crompton and Jenkins (pp45 and 50), Hamilton (p506) and others, are valuable in a reference book of this sort. It is regrettable that the book contains too few of them.

Bibliographical coverage is excellent, with only a few exceptions (for example, the lack of reference to White and Harris' (1977) major work on fossil suids in the chapter by Cooke and Wilkinson; omission of several papers on African Carnivora, for example, of M.G. Leakey, Howell and Petter; and only cursory reference to important contributions by other carnivore specialists, such as Hendey and Ewer, in the contribution by Savage; and because the phylogenetic status of *Ramapithecus* is by no means established, as Simons and Pilbeam readily admit in their paper on this taxon, the inclusion of a larger bibliography and debate pro and contra hominid status of *Ramapithecus* would have further added to the great interest of this chapter).

In several instances good reviews of past and ongoing debates make exciting reading, as in the discussion of cetacean origins and the phylogenetic position of the African Archaeoceti by Barnes and Mitchell. Fortunately for a palaeontological *tour de force* of this length several of the authors have the ability to bring their long-dead creatures to life again. The expression of such ability, from deliberations on brain size and locomotion in the earliest mammals (Crompton and Jenkins) and on the evolution of the ant-eating habit in aardvarks (Patterson), to questions about how deinotheres used their tusks (Harris) and about why sirenians speciate slowly (Domning), adds greatly to a real enjoyment of this book.

In the preface the editors remark: "Such overviews (as this one) are the only means of . . . picking out our significant achievements and failures". On reading through the whole book others too may perceive, as I do, a disturbing failure common to a sizeable block of the present contributions. On the one hand many morphological details are given; on the other, conclusions on relationship (in some cases 'trees') are presented. But between these two there is often an hiatus; that is, it is difficult, at best, to extract precisely which morphological details are considered by the author pro, and which contra, his hypotheses of relationship. The reader is thus unable to test such hypotheses. In individual cases it is not clear whether the author has preferred to base his conclusions only on unsorted impressions; or whether he *has* used a particular methodology to arrive at clear statements supporting his conclusions, but has merely failed to articulate these statements to his readers. Several of the papers stress the paucity and fragmentary nature of the fossils. That such shortcomings do not justify a lack of methodology and clarity is shown by the fact that some contributors on the poorest fossil samples (for example, Crompton and Jenkins on Mesozoic mammals, Hamilton on Cervidae and Palaeomerycidae, Patterson on Pholidota and Tubulidentata, and others) are among those that make the clearest statements in support of their hypotheses of relationship.

This large, sturdy volume, in which printing, reproduction of illustrations, binding and indexing are all of high quality, is unique in fully representing present knowledge of African fossil mammals. Whether or not one's own interpretations (and indeed mode of interpretation) differ from any of those in *Evolution of African Mammals*, there is no better companion than this book for anyone, whether student or specialist, who is interested in African mammal palaeontology. **E.S. Vrba**

E.S. Vrba is Head of the Department of Palaeontology and Palaeoanthropology at the Transvaal Museum, Pretoria, South Africa.

Plastic crystals

The Plastically Crystalline State: Orientationally-Disordered Crystals. Edited by John N. Sherwood. Pp. 383. (Wiley: Chichester, UK, and New York, 1979.) £19.50.

THIS is a valuable and interesting book, dealing with a type of crystal to which increasing attention has been paid in recent years. Plastic crystals are frequently rather arbitrarily defined as those for which the entropy of fusion is less than ~ 20 J K^{-1} mol^{-1}, but the editor wisely decided that his contributors should not be rigidly confined by this limitation, and references are made to orientationally disordered solids not satisfying this entropy of fusion criterion, and occasionally also to salts and to liquid crystals.

The book is essentially a collection of essays by experts on some of the techniques available for investigating orientational disorder in crystals, and especially of newer methods still in the evolutionary stage. There are no accounts of certain techniques which, though admittedly of longer standing, will nevertheless continue to be used, such as experimental thermodynamics and neutron diffraction. The topics covered include methods of studying self-diffusion, diffuse X-ray scattering, dielectric and acoustic studies, NMR, Rayleigh and Brillouin scattering, infrared and Raman spectroscopy, and neutron scattering. There are also chapters on the structures of plastic crystals, on the correlation of dynamic observations of molecular motion, and on the theoretical aspects of orientational disorder. The quality of exposition is generally high, and the text is illustrated by well chosen figures.

A typical chapter describes the theory and practice of the technique with which it is concerned, and there then follow examples of its application to particular systems. In consequence, the sum total of the space devoted to any particular crystal can vary considerably. Thus, there are 29 references in the index to adamantane, 35 to cyclohexane, and 23 to hexamethylethane, which in each case are distributed fairly uniformly throughout the book. On the other hand, there is very little on the plastic crystalline phases of nitrogen, oxygen, carbon monoxide and fluorine, even though these have received a good deal of attention on account of their comparative molecular simplicity.

When this book has so much to commend it, it is a pity to have to add that it contains more minor misprints and mistakes than one might have expected to find. However, these are minor blemishes on a book which should be a real asset to those actively interested in the subject.

LA.K. Staveley

Control of movement and posture

An Introduction to Physiology. Vol.4. By H. Davson and M.B. Segal. Pp.573. (Academic: London; Grune and Stratton: New York, 1978). £11.80.

THE latest volume in this impressive series is devoted to the control of movement and posture, which it treats in considerable depth. The first section begins with an instructive general account of quadrupedal locomotion which, as much experimental work is performed on four-footed subjects, is clearly justifiable on scientific grounds, but may not be thought wholly relevant by readers primarily interested in man.

This is followed by a brief discussion of the grading of muscular effort and a detailed description of proprioceptive sensors leading on to a consideration of spinal reflexes, which starts from the work of D.P.C. Lloyd in 1943 rather than, as might have been expected, from that of Sherrington. In this chapter the contributions of the Matthews, father and son, to spindle-physiology, together with modern views on the significance of the tendon organs, are surveyed.

The second section of the book is concerned with supra-spinal control of motor activity and contains chapters on the vestibular apparatus, cerebral cortex, cerebellum, reticular, olivary and red nuclei, and also the basal ganglia. The final chapter comes full circle and returns to broader aspects of the coordination of movement. In dealing with topics as complex as these it is immensely difficult to create for the first-time reader (for whom, presumably, an 'introduction' is intended) a clear and coherenet outline but a brave effort has been made and, on the whole, successfully.

The text is conveniently subdivided by frequent and informative headings and is copiously illustrated and documented with references. Most of the illustrations display the experimental results obtained by the investigators whose work is discussed while the remainder are explanatory diagrams.

My assessment of the status of this multi-volume treatise was incorporated in the review of an earlier volume see (*Nature* **266**, 284; 1977) and remains unchanged.

R.V. Coxon

R. V. Coxon is Reader in Human Physiology at the University of Oxford, UK.

Published today are the two latest additions to the *Contemporary Biology Series:*

An Introduction to Evolutionary Genetics
David T. Parkin

The author shows how an understanding of the genetic structure of populations and the forces that interact with this can produce evolutionary change. Introductory sections on metric characters and molecular evolution and a wide range of examples from experimental and field studies assist in developing the principles of how evolution can occur as a result of gene substitution.

This is a topic of great biological importance, but it is often considered theoretically rather difficult. In this book, Dr Parkin presents and discusses the genetic basis of evolution and speciation in a clear way, maintaining a careful balance between the ecological and the theoretical aspects of the subject.

Paper £6.50

The Biology of Parasitism

An introduction to the study of associating organisms
Philip J. Whitfield

This new textbook of parasite biology avoids the traditional view of parasitism as a discrete way of life and shows convincingly that it is an often arbitrarily defined part of a broad spectrum of associations between organisms. In doing this, Dr Whitfield rejects the taxonomic approach and instead organises his material around themes such as nutrition, physiology and regulation, behaviour, and ecology and evolution.

Important advances have been made in many of these areas over the past decade. The use of new technologies, such as scanning electron microscopy, and new conceptual approaches, such as the application of rigorous population dynamical theories to association biology, have contributed largely, but many of these developments have not, until now, been reported in undergraduate texts.

Dr Whitfield has used this new material most effectively in his carefully distilled arguments by concentrating on thoroughly researched examples. His style is clear and lively and the writing is supported by excellent diagrams and electron micrographs.

Stellar evolution

Stars and Clusters. By Cecilia Payne-Gaposchkin. Pp. 261. (Harvard University Press: Cambridge, Massachusetts, and London, 1979.) £13.50; $22.50.

PAYNE-GAPOSCHKIN was in no small way responsible for my deviation from the straight and narrow path of pure physics to the ethereal delights of astronomy. I devoured her book *Introduction to Astronomy* (Eyre and Spottiswoode, 1956) during my second year at university and never looked back. That book, like *Stars and Clusters*, is intended for the student and the general reader who may have little background in mathematics or physics. To this end *Stars and Clusters* is written without recourse to any mathematical formula; not a single equation graces its pages. Our inumerate unphysical friend can therefore romp through the text with ease.

But what about the figures? I was immediately struck by the fact that the figures must be considerably more difficult to understand than the text if you didn't "have the mathematics". The intricacies of the Hertzprung-Russell diagram especially when it contains multiple stellar evolutionary tracks are difficult enough to grasp at the best of times. Our non — mathematical student has probably never drawn a graph in his life, has no idea what a logarithm is and must be confused by the unexplained leap from (B—V) to log surface temperature for the abscissa without the added complication that the later scale is inverted. It is highly laudable to write a book with the non — mathematical student in mind, but if this student is to gain most from the book I think he must be taught some maths on the way; he must, to quote Martin Johnson, "discover for himself how little armoury he needs for appreciating the beauty and convincement of tracing an argument in symbols and actual quantities".

Stars and Clusters falls between two stools. The inumerate student would appreciate help with the graphical concepts and the numerate student would benefit greatly from a mathematical treatment. This of course isn't to say that I did not enjoy reading the book. I did. But I was constantly reminded that one small equation must be replaced by many and complex words if the same message is to be conveyed.

The main theme of the book is the effect of evolution on stellar characteristics, the physical processes underlying stellar evolution and the light thrown on to this problem by the observation of open clusters, globular clusters and variable stars. The book is impressively illustrated and it is obvious that enormous care has been taken in the choice of the figures. An indepth study of the Hyades cluster in Taurus is used to introduce the early stages of stellar evolution, and one of the figures is a plot of apparent visual magnitude as a function of (B—V) colour for all the stars in the Hyades field of view. The interpretation of this figure would be a fascinating problem for a first-year astronomy student at university. The same can be said of a figure in the next chapter, the path of a metal rich star of five solar masses on the Hertzprung-Russell diagram. I have the sneaking suspicion that both these would leave the amateur astronomer way behind. The book contains about thirty figures showing photographs of clusters and absolute magnitude against colour plots of their stars; again a fascinating study for the university student. A careful distinction is made between the evolution of single stars and the peculiar mutual influence that double stars exert on each other and on their evolution. The book contains a superb collection of light curves for variable stars; one indication of its thoroughness is that there are 48 for R.R. Lyrae stars alone! The AAVSO star atlas is included at the end of the book so if you want to find, for example, X Geminorum you are shown where to look.

I am going to recommend this book very strongly to my first-year university students. They will be able to understand the figures, and will not need all the footnotes that rather verbosely explain the simple physical concepts. It may seem strange but the fact that it contains no mathematics makes me reluctant to recommend it to an inumerate student. Many of the concepts introduced and most of the concepts illustrated need a more detailed and also a more numerate explanation to make then understandable.

David W. Hughes

David W. Hughes is Lecturer in Astronomy and Physics in the Department of Physics at the University of Sheffield, UK.

Conidium ontogeny

Patterns of Development in Conidial Fungi. By G.T. Cole and R.A. Samson. Pp. 190. (Pitman: London, San Francisco and Melbourne, 1979.) £29.75.

SINCE S.J. Hughes in 1953 firmly placed developmental characteristics of conidial fungi amongst the prime ones for classifying Fungi Imperfecti, studies of conidium and conidiophore ontogeny have galloped apace. There is no doubt that these researches have generated abundant new taxonomic criteria or have illumined established ones. The difficulty has largely been in judging the significance of these characteristics. The fact that a number of attempts have been made to erect more or less formal classifications based primarily on features of conidiophore and conidium development shows that conidial fungi undoubtedly *can* be classified by means of these criteria, but what is less clear is whether such classifications reflect the phylogeny of the organisms concerned.

It is because the taxonomic significance of ontogenetic data is still an area of lively controversy that this new book is such a timely and valuable contribution. The authors have brought together an enormous amount of information, chiefly in pictorial form and much of it original (mainly as new scanning electron micrographs), so that the theorising mycologist who wishes to reclassify the fungi and the morphogeneticist who wants to find how fungi come to look the way they do have very little need to look at real live fungi — at least, while they are planning how best to go about their studies. The quantity of factual information is so large and the authors' presentation so good that virtually all that is needed for armchair speculation is available here in a single convenient volume. The authors themselves are reticent about the formal taxonomic implications of the book's contents. They are explicitly and unambiguously concerned with patterns of conidial development, and it is these which they classify, not the fungi themselves.

Two-thirds of the book deals with various modes of conidium ontogeny in Fungi Imperfecti, chiefly hyphomycetes. The remainder includes an account of techniques for studying the development and ultrastructure of conidial fungi. Because so many of the electron micrographs presented are original it was wise of the authors to have included this chapter which effectively amounts to a 'materials and methods' section. There is also a major section on patterns of sporangiospore development in Zygomycetes which serves to illustrate how another group of mycelial organisms has solved problems similar to those facing higher fungi. A glossary eases the way for those not familiar with the subject's specialised terminology.

The text is copiously and beautifully illustrated and astonishingly free from printing errors. The authors write well (that is, they say precisely what they mean), and though they use specialised terms where appropriate, they eschew jargon. The high quality of the book's format is reflected in its price, but despite this it is likely to appear in most mycology teaching libraries, as it furnishes in convenient form so many data and concepts. Researchers in the field of fungal taxonomy and developmental biology will use it for these reasons and as a source of esoteric pleasure.

M.F. Madelin

M.F. Madelin is Reader in Mycology at the University of Bristol, UK.

CENTRALLY ACTING PEPTIDES
Edited by J. Hughes

A Biological Council Symposium on Drug Action

The April 1977 symposium was stimulated by the dramatic increase in research into functionally active peptides in the central nervous system, and the discovery of new peptides such as neurotensin, the enkephalins and the endorphins. All aspects of research – biochemical, electrophysiological and behavioural, as well as radio-immunoassay and radiofluorescence – are covered in this volume, which also points out the many gaps that still remain in our understanding of the subject. It is thus a timely review of the current state of research, and will be invaluable to anyone involved in any aspect of peptides.

Contents
Isolation and Identification of Biologically Active Peptides; H. R. Morris
Immunohistochemical Localisation of Peptides in the Nervous System; R. Elde, T. Hökfelt, O. Johansson, A. Ljungdahl, G. Nilsson & S. L. Jeffcoate
Are 'Hypothalamic Hormones' Central Neurotransmitters?; M. J. Brownstein
Diffuse Neuroendocrine System: Peptides Common to Brain and Intestine and their Relationship to the APUD Concept; A. G. E. Pearse
Electrophysiological Analysis of Peptide Actions in Neural Tissue; L. P. Renaud & A. Padjen
Comparative Features of Enkaphalin and Neurotensin in the Mammalian Central Nervous System; S H. Snyder, G. R. Uhl & M. J. Kuhar
Behavioural Effects of Hypothalamic Peptides; A. J. Prange Jr, C. B. Nemeroff & P. T. Loosen
Substance P: A Historical Account; F. Lembeck
Substance P: Binding to Lipids in Brain; F. Lembeck
Distribution and Release of Substance P in the Central Nervous System; A. C. Cuello, P. Emson, M. del Fiacco, J. Gale, L. L. Iversen, T. M. Jessell, I. Kanazawa, G. Paxinos & M. Quik
Endogenous Opioid Peptides: Historical Aspects; H. W. Kosterlitz
Physiological and Clinical Relevance of Endorphins; L. Terenius & A. Wahlström
Pharmacological and Biochemical Aspects of the Enkephalins; J. Hughes, H. W. Kosterlitz, A. T. McKnight, R. P. Sosa, J. A. H. Lord & A. A. Waterfield
Distribution and Pharmacology of the Enkephalins and Related Opiate Peptides; R. J. Miller, K.-J. Chang, P. Cuatrecasas, S. Wilkinson, L. Lowe, C. Beddell & R. Follenfant
Electrophysiological Effects of Opiates and Opioid Peptides; P. B. Bradley, R. J. Gayton & L. A. Lambert
Biogenesis and Metabolism of Opiate Active Peptides; D. G. Smyth, B. M. Austen, A. F. Bradbury, M. J. Geisow & C. R. Snell
Behavioural Effects of Neuropeptides Related to -LPH; D. de Wied

UK Price £12.95, 0 333 23476 6,

IBIS

International Book Information Services

Is the information you receive on current publications

.... up to date?

.... directed personally to you?

.... related specifically to your professional needs and interests?

IBIS already provides a free information service to university staff throughout the world. Over 1,000 publishers use IBIS lists to send out information on books and journals related to the specialised interests of the academic concerned.

We now plan to offer this service to professional scientists working in private industry and public organisations. IBIS will send out questionnaires over the next few weeks to many people in research throughout the UK and Europe.

The purpose of the questionnaire is to find out from scientists their precise professional and research interests. They can select their specialisations from over 1,400 different subjects. The replies will be loaded on to the IBIS computer and from then on they will only receive information about their particular interests.

IF YOU DO NOT RECEIVE A QUESTIONNAIRE YOU ARE STILL ABLE TO RECEIVE INFORMATION THROUGH US. SIMPLY WRITE OR PHONE US ASKING FOR A QUESTIONNAIRE.

Monographs for Students of Medicine

Control of Human Reproduction

R. L. Holmes and C. A. Fox

October/November 1979, viii + 150pp., £5.50/$12.50 0.12.353450.X

Control of Human Reproduction aims to bridge the gap between the basic sciences and clinical knowledge of the endocrinology of reproduction. The authors present a general survey of the role of hormones in reproductive processes with particular reference to the human system, giving the anatomical, physiological and chemical facts and their clinical applications. The book gives a clear exposition of the reproductive hormones, the tissues which produce and control them, and the way in which a variety of factors bring about the development of functional reproductive systems and influence them in maturity. The mechanisms of reproduction and Man's ability to control his own numbers and to affect his environment are considered, as well as abnormalities of development and disorders of reproduction. The combination of a basic approach with clinical applications makes the book of value to medical students throughout their course and to practising clinicians.

Aircrew Stress in Wartime Operations

edited by E. J. Dearnley and P. B. Warr

October/November 1979, vii + 224pp., £8.50/$20.00 0.12.207750.4

This is a book of important research papers in psychology and psychiatry. They were first published between 1940 and 1948, being sponsored by the Flying Personnel Research Committee of the Ministry of Defence. They are of major historical significance, but the current upsurge of interest in the sources and management of stress ensures their topicality. Many themes and methodological features are of central importance for today's investigators. The papers describe eight research projects to examine the performance of aircrew during the second world war. The projects range from statistical investigations of accidents and effectiveness, through more clinical studies of personality and individual functioning, to the classic psychological experiments into fatigue and pilot error. The eight research reports are preceded by a specially written account of the historical background to the studies. The book provides a fascinating insight into developments during a period when behavioural research achieved considerable advances.

Handbook of Microbiological Investigations for Laboratory Animal Health

J. R. Needham

October/November 1979, xviii + 174pp., £9.80/$21.00 0.12.515950.1

The information presented in this book is based principally on microbiological techniques employed by the author at the Clinical Research Centre in their animal health programme. This scheme is described in the book in full detail with its various stages set out together with the laboratory tests necessary to monitor animal health. Each chapter describes the application and results of tests used for animals including mice, dogs, farm animals and subhuman primates; thus the animal health worker is provided with data than can be compared with his own findings. In addition, the details are included for several experiments which were carried out in a search for alternative methods. Designed as a reference work and bench book for microbiologists and animal health scientists, this book should provide an invaluable guide for all institutions which make use of animal laboratories for agricultural, medical, commercial or veterinary purposes.

Surgical Sepsis

edited by C. J. L. Strachan and R. Wise

October 1979, x + 154pp., £11.80/$25.00
0.12.794378.1 (Academic Press)
0.8089.1208.9 (Grune & Stratton)

The symposium, of which this book is the proceedings, was designed to provide a platform for the review and discussion of methods currently in vogue for the prevention of abdominal wound sepsis. The speakers were chosen for the recent contributions they have made advancing the state of knowledge concerning the factors involved in wound sepsis, and included one of the 'fathers' of surgical sepsis research in the U.S.A. — Professor Harlan Stone. Their topics range from the mundane 'hot appendix' to the more esoteric and, until recently, poorly understood syndrome of pseudomembranous colitis, trials of wound guard, wound sprays or instillates of topical bacteriocides. The text will undoubtedly benefit surgeons and microbiologists as well as medical students and workers within the pharmaceutical industry, and is likely to provide the standard reference work for the next decade.

Language, Thought and Culture: Advances in the Study of Cognition

Classifications in their Social Context

edited by Roy F. Ellen and David Reason

October/November 1979, xii + 262pp., £13.00/$30.00 0.12.237160.7

The comparison of different forms of classification raises fascinating and fundamental questions. Is the tendency to classify the result of the way in which we process information (a logical or material imperative), or is it the result of more localized pressures (a social or historical imperative)? Do the terms, logic and structure of these forms of classification reflect the logic and structure of a particular society, or do they mould the social environment so that it too may become comprehensible? Do we discriminate socially because we are bound to classify in a discriminatory way, or vice versa? This book approaches these problems in two ways. The majority of the papers draw on examples of 'folk' and 'scientific' classification in a specific ethnographic or historical context. Together they provide a comparative approach that allows the remaining papers to relate the problems of understanding classification to current debates in anthropology and sociology, especially concerning the relationship between knowledge, symbolism and socio-economic activity.

Quantitative Cytochemistry and its Applications

edited by J. R. Pattison, L. Bitensky and J. Chayen

October/November 1979, xvi + 322pp., £14.00/$32.50 0.12.546750.8

A two day international meeting was held in London on November 13 and 14, 1978, supported by the Section of Pathology of the Royal Society of Medicine, entitled "Quantitative Cytochemistry and its applications". This volume, which is published in relation to, and has taken the same title as, this meeting, presents revised and expanded papers dealing with the range of applications of quantitative cytochemistry to medical research. Although the methods used in such studies are described in some detail, emphasis is placed on application and the relevent information obtained rather than on the minutiae of techniques; full references are given for those who wish to study the methodology in more detail. This is the first time that the diverse applications of this subject have been collected together in one volume demonstrating that the results obtained by cytochemical methods yield valuable information and useful answers in medicine, toxicology and biochemistry.

A.P.I.C. Studies in Data Processing No. 15

Computer Architecture: A Structured Approach

R. W. Doran

October/November 1979, x + 234pp., £14.20/$30.00 0.12.220850.1

In this book the author adopts a new approach to the subject, discussing the principles behind computer architecture and at the same time illustrating these principles by developing a detailed description of one machine, the Burroughs B6700. The first part of each chapter is spent in building a general model of what the architecture of a general purpose computer is designed to achieve, laying down the various functions in easy stages to work up gradually to the full complexity of the machine. In the second half of each chapter the functional architecture of the B6700 is described and assessed in terms of the model. In general the text assumes a fairly broad knowledge of computers though not of computer architecture itself, and does not hesitate in going back to basics where necessary to clarify a principle. This book provides an ideal introduction both to the principles of computer architecture and to how they are implemented.

Interaction within the Brain Pituitary Adreno-Cortical System

edited by M. T. Jones, B. Gillam, M. F. Dallman and S. Chattopadhyay

October/November 1979, c280pp., £14.80/$34.50 0.12.389150.7

The book is based on a satellite symposium of the Vth International Congress in Hormonal Steroids held at Varanasi, India, in November 1978. The contributions are representative of the broad range of experimental strategy and clinical observations that are being used to further our understanding of a complex interacting system. Although due prominence is given to recent discoveries concerning the corticotrophin-related and ß-lipotrophin-related peptides, care was taken to ensure that aspects of the subject that are frequently neglected were adequately covered. The scope of the book is well reflected by the range of specialists who have contributed chapters, including endocrinologists, anatomists, clinicians, pathologists, physiologists, neurologists, pharmacologists, biochemists, behavioural scientists and developmental biologists.

Pasture and Politics

Economics, Conflict and Ritual among Shahsevan Nomads in Northwestern Iran

Richard Tapper

October/November 1979, xvi + 312pp., £17.00/$39.50 0.12.682660.4

Questioning the validity of stereotypes, the author examines the relation between grazing rights, local community politics and ritual behaviour among the Shahsevan nomads of northeastern Azarbayjan, in Iran. In the first chapter of the book the author underlines the importance of these issues for comparative and theoretical study, while the final chapter places the Shahsevan in a broader perspective by comparing them with some other societies, and draws some general conclusions about the relation between territorial and political organisation. The author's unusual material and approach will be of considerable interest to teachers, researchers and students in the fields of social anthropology, cultural geography, Middle Eastern and Islamic studies, and development economics.

Environmental Chemistry of the Elements

H. J. M. Bowen

November/December 1979, xvi + 334pp., £17.00/$39.50 0.12.120450.2

This book aims at a comprehensive and critical rather than encyclopaedic summary of the data of environmental inorganic chemistry. The first four chapters deal with the air, water, rocks and soils, and stress the dynamic nature of elemental cycling in these media. The cycling of the organic elements carbon, hydrogen, oxygen, nitrogen and sulphur in the biosphere has a chapter to itself. The elemental composition of living matter is reviewed with the help of tables of selected data. Other chapters are concerned with the uptake and excretion of elements by plants and animals, together with criteria for essentiality, toxicity and deficiency. Two chapters cover biological fractionation of isotopes, and the occurrence of natural and artificial radionuclides in the environment. Environmental disturbances through human activities are summarised in the penultimate chapter. A special feature is the last chapter which reviews the date available for each of the elements in turn.

The Institute of Mathematics and its Applications Conference Series

Mathematical Aspects of Marine Traffic

edited by S. H. Hollingdale

October/November 1979, xii + 270pp., £17.50/$40.50

This book contains papers that were presented at a two-day conference held at London University and organised by the Institute of Mathematics and its Applications in collaboration with the Royal Institute of Navigation and several other organisations. The two-fold purpose of the conference was; to bring marine traffic to the attention of applied mathematicians as a rewarding field of research, and to inform marine navigators and technologists of the varied contributions that a mathematical approach can make in their field. The contents of this book bear witness to the importance and versatility of mathematical models in marine traffic studies, and also to the current pre-occupation with routeing schemes. The papers will be of professional interest and great assistance to applied mathematicians and marine engineers working in government and industry and also of educational use to undergraduates and teachers.

Comparative Physiology of Osmoregulation in Animals

edited by G. M. O. Maloiy

Volume 1

October/November 1979, xii + 678pp., £43.50/$91.50 0.12.467001.6

Volume 2

November/December 1979, xii + 246pp., £18.60/$43.00 0.12.467002.4

In these two volumes much work has been brought together in comparing the special adaptive mechanisms that have evolved in a variety of animals for solving the physiological problems facing them in maintaining ion and water balance. The general principles underlying osmoregulation are discussed, as well as specific regulatory systems found in different groups of animals, each chapter dealing with a separate group with reference to particular environments. In addition, the mechanisms of ion transport occuring in may tissues are considered, with detailed accounts of some important cases including kidney tubules, malpighian tubules, fish gills and nasal salt glands. Few researchers can be expert in all these areas, from fresh water invertebrates to desert camels, but with these volumes they now have access to the latest developments in the field.

Computational Mathematics and Applications

Stable Recursions

With applications to the numerical solution of stiff systems

J. R. Cash

November/December 1979, c220pp., £19.60/$45.50 0.12.163050.1

The main aim of this book is to establish a relationship between the theories of linear recurrence relations and ordinary differential equations and to exploit this relationship to produce new algorithms for the numerical integration of ordinary differential equations. This oook is not intended as an introduction to finite difference methods, but it is hoped that the material presented wil help the reader to deepen his understanding of this particular class of methods. It is a research work with many open ended questions and includes several sections which are supposed to stimulate further research. It also shows that many of the currently used methods are particular cases of much larger families of methods, which are as yet unexploited. For these reasons the book should be of interest to anyone involved in the numerical solution of differential equations.

The Molecular Physics of Liquid Crystals

edited by G. R. Luckhurst and G. W. Gray

October 1979, xiv + 494pp., £20.00/$46.00 0.12.458950.2

This book has its origins in a NATO Advanced Study Institute whose primary aim was to clarify the present situation by discussing both theoretical and experimental approaches used to study liquid crystals at the molecular level. The result is not only a unique reference work but, by virtue of the original research described, a stimulus for further investigation. Among the experimental techniques discussed are magnetic resonance, spectroscopy, neutron, X-ray and light scattering, as well as thermodynamic measurements. The statistical mechanics necessary to understand the theory of liquid crystals are reviewed and then used to consider molecular-field and hard-particle theories of nematics and cholesterics. This book is not aimed exclusively at physicists and chemists, but contains much that is of value to engineers, applied physicists, electronic engineers and pure theoreticians.

Beta-lactamases

edited by J. M. T. Hamilton-Miller and J. T. Smith

October/November 1979, xii + 500pp., £26.40/$61.00 0.12.321550.1

The Editors of this book, both of whom have been actively involved in this topic since the introduction of the first semisynthetic penicillins, have tried to bring together some important aspects of ß-lactamase, both conceptual and practical. The chapters should be of interest to a very wide audience, and will provide an overall view of our present understanding of this important group of enzymes. Not only research workers in Universities and Industry, but also members of hospital departments of Medical Microbiology, Pathology and Pharmacology, and biochemists, immunologists, geneticists and molecular biologists, will find much of lasting and practical interest to them in this volume.

Soil-Borne Plant Pathogens

edited by B. Schippers and W. Gams

October/November 1979, xvi + 686pp., £27.00/$62.50 0.12.624850.8

This book presents the proceedings of the fourth International Symposium of Soil-borne Plant Pathogens which was part of the third International Congress of Plant Pathology, held in Munich in August 1979. Much of the research currently being done on soil-borne plant pathogens is aimed at finding biological and integrated control of the diseases they cause, and it was this aspect of the subject which was emphasised throughout this meeting. Among the topics discussed were the dynamics and density of populations of soil-borne plant pathogens, the effects of changes in soil and crop management, side effects of pesticides on non-target organisms, interactions with other micro-organisms, and the biotic and abiotic factors of the soil ecosystem antagonising and suppressing pathogen populations and disease development.

Economic Microbiology Volume 3

Secondary Products of Metabolism

edited by A. H. Rose

October/November 1979, xvi + 590pp., £34.00/$78.50 0.12.596553.2

This third volume in the series is, like the other volumes, intended to provide an authoritative and lasting reference work on a separate topic in industrial microbiology, with particular emphasis on the chemical activities of micro-organisms. Volume 2 dealt with primary products of metabolism, and here the concern is with these secondary products that have economic importance. Following a general chapter on the commercial production of secondary products of micro-organisms, the authors discuss the basic microbiology and biochemistry of various groups of these compounds. More than half the book is devoted to antibiotics, for which there is an abundance of data, and the rest of the volume contains chapters on several other important groups of secondary products.

Microtubules

edited by R. Roberts and J. S. Hyams

October/November 1979, c600pp., £34.00/$71.50 0.12.590750.8

The last fifteen years have seen a vast increase in our knowledge of microtubules and their functions. The editors of this work feel that the first phase of microtubule research is almost at an end and that the next phase is slowly emerging. This book concentrates on those areas of research which are genuinely exciting now and are going to form the basis for future advances in this field. Important and key questions which will be answered in the next decade or so will depend for their answers on the core of information presented in this book. It covers such topics as the molecular structure of tubulin, the mechanism and control of its *in vivo* assembly, how microtubules function in the cell in motility and mitosis, and the precise functioning of nucleotides, ions and accessory proteins.

Modern Aspects of Microwave Spectroscopy

edited by G. W. Chantry

October 1979, xvi + 514pp., £38.00/$89.50 0.12.168150.5

This book serves a dual purpose. First, in bringing together experts from these and other branches of microwave spectroscopy, it should go a long way towards reducing the isolation in which recent research has been conducted and reported. To this end a comprehensive bibliography has been included at the end of each chapter. Secondly, each topic receives extensive critical discussion, which forms an up-to-date commentary on the progress in that area. These factors combine to make the book a valuable addition to the library of any firm, research institute, university or government department involved with microwave research.

East African Mammals Volume IIIB

An Atlas of Evolution in Africa

Jonathan Kingdon

November 1979, iv + 430pp., £55.00/$126.50 0.12.408343.9

Naturalists will have been waiting eagerly for this penultimate part to the third volume of Jonathan Kingdon's treatise: *East African Mammals*. His extraordinary drawings that reveal fine structural and anatomical details with such clarity, and the dedication and thoroughness with which the text of earlier volumes was invested have earned international acclaim. As a *tour de force* of artistic and scientific merit there can be few comparisons in its field. Part B of the third volume moves on from the carnivores of Part A to the large mammals for which Africa is so famous: the elephants, rhinos, the equids including the strange Painted Quagga, the pigs, the hippopotamuses, the camels, the chevrotains and giraffes. Broadly, it sets out to portray the role of these beautiful animals in tropical Africa's ecology and the evolutionary and functional significance of their curious forms and markings. The searching text is enhanced throughout, as in earlier volumes, by the author's exquisite drawings and sketches.

DENSITY MARKER BEADS NOW AVAILABLE
for calibration of gradients of Percoll

MIX AND SPIN PERCOLL™

Now centrifugation is simpler,
quicker and gives much greater resolution
than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

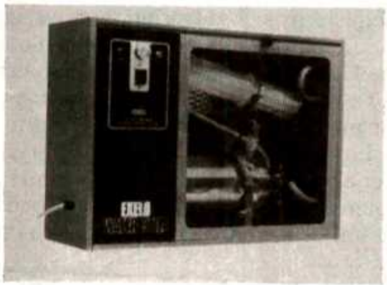
newly on the market

Enclosed water still. Exelo. There is now an addition to the Exelo range — a new water still enclosed in a clear-fronted metal case. Special features include a radically redesigned horizontal boiling chamber, combined with an inclined condenser. The metal cabinet can be bench-standing or wall-mounted. Heating elements may be made either with silica sheath where maximum purity is paramount, or with metal where maximum output is preferred. The output with silica elements is up to 3 l h^{-1}, and with metal elements 4 l h^{-1}. Both models have a thermostatic safety cut-out as well as a constant level device fitted to the boiling chamber.

Circle No. 87 on Reader Enquiry Card.



The Exelo enclosed water still

Desk-top computer/printer. Dynatech. A compact mini-computer/printer has been introduced by Dynatech Laboratories which can accept and perform computations on raw data from a wide range of instruments, such as Dynatech colony counters, which have a 4-bit BCD output. Designated the model 700, it is primarily designed for use with Dynatech model 980 and 880 macro/micro colony counters, but is also compatible with other similar counting systems. This 'desk-top' mini computer/printer can be removed from the primary instruments and used to handle a wide range of laboratory functions. Also, by removing a plug, the unit can be used to enter data manually. The range of equipment available includes a programmable calculator, a magnetic card programmable calculator and solid state software libraries. An 'alerting operator' programme ensures error-proof operation. At each stage of the computation the machine will inform the operator when more data are required to carry out the programme. The computer/printer module comprises a calculator which is locked onto the body of the printer. The thermal printer, which can provide alpha/numeric data and can plot curves and histograms, prints at a rate of 60 characters per s. Power requirements are 115 V, 60 Hz.

Circle No. 88 on Reader Enquiry Card.

Whole specimen preservators. VirTis. A range of preservator systems is available from VirTis, designed for use with their range of laboratory freeze dryers. Slow freeze-drying of whole specimens retains a physical appearance extremely close to that of the original. The absence of water in freeze-dried specimens allows safe storage and display at normal room temperature and humidity. Freeze drying is also the most labour-effective method of preparing a large number of specimens for teaching purposes. Refrigerated preservator chambers can be built large enough to house any animal, but for large specimens a more economical method is to place the vacuum chamber inside an existing storage freezer and a vacuum line run to the freeze dryer. A thermistor probe is then inserted into the deepest point of the animal to sense when it is fully frozen, and later when it is fully dried.

Circle No. 89 on Reader Enquiry Card.

Refractive index detector. Du Pont. The Du Pont refractive index detector is a stable drift-free instrument that is sensitive to any sample component whose refractive index is different from the mobile phase. Operation of the detector is based on Snell's law which measures the light beam deflection caused by the refractive index difference between the sample and the pure mobile phase. The unique flow cell housed in a Dewar flask eliminates the need for a liquid bath and minimises drift caused by temperature changes. Adjustable transparent plates are used to balance the light beam. Manual adjustment of the plates balances the light intensity of the two matched cadmium sulphide photocells.

Circle No. 90 on Reader Enquiry Card.

Waste box. Lawtons have developed a purpose-designed waste box for the safe and effective disposal of non-combustible material such as glass and aerosol cans. Manufactured from mystaline impregnated board with an oyster finish, the Lawco glass and aerosol waste boxes are of a very tough and strong construction which is waterproof, resistant to penetration by sharp glass, and not liable to collapse when picked up. Delivered in flat form but erected easily and quickly without tape, staples or adhesive, these waste boxes have a chute-type opening at the top which folds down flat against the side when the container is full. With a capacity of 42,050 cm^3 and dimensions when assembled of 50 cm × 29 cm × 29 cm, Lawco glass and aerosol waste boxes are supplied in packs of 25.

Circle No. 91 on Reader Enquiry Card.

Automatic liquid nitrogen level controller. Edwards. Liquid nitrogen levels in process and storage vessels can be controlled automatically and reliably using the ALC7, a new, compact instrument from BOC Cryoproducts. The ALC7 uses two diode sensors to provide high and low level probes for pre-set level control, and a third probe to operate an audio low level alarm. For operator safety the ALC7 uses a stabilised 12 V, d.c. power supply unit which is connected to the mains. The controller operates a 12 V Cryoproducts Dewar pump or solenoid valve fitted to a suitable storage vessel, providing also a visual level indication by means of indicator lamps. A manual override button is also provided.

Circle No. 92 on Reader Enquiry Card.

One of the Carle Series-Sx gas chromatographs

Gas chromatograph. Carle. There is now a new facility for the range of gas chromatographs from Carle Instruments. The Series-Sx offers automatic specific analyses under control of the laboratory's data handling system or a microprocessor integrator with external timed event capability. Operation is based on automatic sample injection and column switching by motor-driven valves. The instrument has separate control channels for operations of up to four valves, or a combination of valves and other functions such as recorder on-off or solenoid operation. The Series-Sx is offered in all 20 application configurations currently available from Carle.

Circle No. 93 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Dynamic balancing machine. B & K Laboratories have introduced a new universal balancing machine, the Type 3905, which is designed for use in conjunction with a new all electronic balancing machine console, the Type 2504. The 3905 is designed for 2-plane balancing of work pieces from 10 kg down to 0.5 kg, at either 1,500/1,800 or 3,00/3,600 r.p.m. A precision cardan shaft end-drive to the work piece permits positive and fast identification of the unbalanced position in both correction planes. The 3905/2504 combination permits a balance of quality grade G1 (ISO 1940) to be obtained and the unbalanced reduction ratio achievable is 90–95%.
Circle No. 94 on Reader Enquiry Card.

Digital cassette recorder. Memodyne has introduced a new computer controlled cassette recorder system called the M80. With a data capacity of 500 kilobytes, the M80 can transfer this data at programmed rates up to 19,200 baud. All potential errors are automatically retried and rewritten if the tape medium is at fault. All recorder controls and communication functions are interrupt driven and transparent to user programs. Two spare bus slots permit additional chips of dynamic RAM to be used for interfacing other peripherals such as keyboards, displays, complete terminals and printers.
Circle No. 95 on Reader Enquiry Card.

Array processor. CSPI. A 64-bit array processor, designed for scientific and engineering applications, has been announced by CSP. The new MAP-6400 interfaces to most popular 16- and 32-bit computers. All arithmetic operations are full floating point in a 64-bit hexadecimal format which provides over 16 decimal digits of precision. The major feature of the MAP-6400 is its unique combination of speed and precision at modest cost. The MAP-6400 has its own internal operating system and executive processor which performs all sequencing and control of tasks.
Circle No. 96 on Reader Enquiry Card.

X-Ray tube. IBM. A new kind of X-ray tube for the microscopic study of living cells has been invented by an IBM research scientist. The new tube produces short bursts of X rays that are enormously more intense than can be obtained from conventional tubes, or even from particle accelerators such as synchrotrons. In exposing X-ray sensitive materials, the new tube can produce an exposure in 100 ns. The tube is small, simple and inexpensive, and 'soft' X rays, with a wavelength of 10–100 Å, a wavelength range ideal for exposing X-ray resists. The tube achieves its remarkable output intensity by creating an extremely dense and hot plasma and concurrently sending through the plasma an electron beam with an intensity of 200 MA cm^{-2}.
Circle No. 97 on Reader Enquiry Card.

Catalogue of chemicals and supplies for radioassay. Packard. The new catalogue of chemicals and supplies lists the products which Packard has available for liquid scintillation and gamma counting. The 26-page catalogue now includes a "Sample Preparation Guide" to help the laboratory technician find the best sample preparation method and scintillation cocktail for 14 different groups of samples. The guide highlights some of the new scintillation cocktails introduced by Packard. The Chart and Table section provides reference tables that are handy for the laboratory, and includes decay tables, information on counting statistics and the properties of common radionuclides.
Circle No. 98 on Reader Enquiry Card.

Automatic blood oxygen dissociation analyser. TCS. The continuous oxygen equilibrium curve of blood can easily be obtained with the TCS Hemox-analyzer. Less than one drop of whole blood or haemolysate and less than 20 min of recording time are required to plot a complete oxygen dissociation curve, and thus obtain the P_{50} value of haemoglobin. The Hemox-analyzer provides an accurate and repeatable dissociation curve of normal and abnormal haemoglobins, including cord blood. No special preparation of the blood sample is required, as the blood is simply added to the buffer–serum solution before starting the recording.

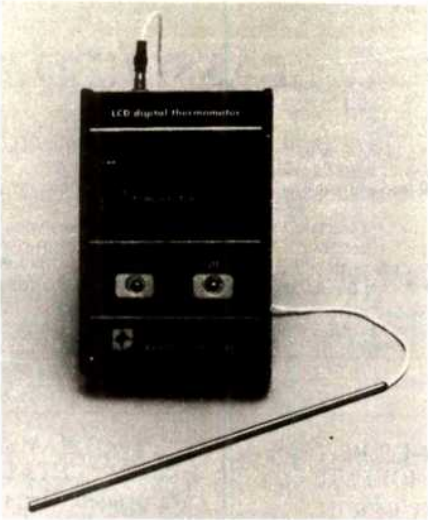
Laboratory hotplate. Corning. A new generation of laboratory hotplates is announced by Corning. This range comprises the Model PC-35 (hotplate) Model PC-351 (hotplate with integral magnetic stirrer) and Model PC-353 (magnetic stirrer only). All three models have a unique design feature in the Pyroceram top plate, a tough glass ceramic. Pyroceram is pretreated for resistance to thermal shock, and offers considerable advantage over iron, aluminium and steel-topped competitive models, due to its resistance to corrosion, excellent uniform thermal conductivity for even heat-up, strength, and an easy to clean surface. Models PC-351 and PC-353 with stirring facilities are supplied with a corrosion-resistant PTFE-coated stirring bar. A powerful magnetic motor located under the top plate guides the stirrer bar with complete control at speeds variable up to 1,000 r.p.m. Surface area of all models is 225 cm^2 and temperature settings are variable up to 510°C. Heat-up is uniform over the whole top and maximum temperature can be achieved in 9 min.
Circle No. 100 on Reader Enquiry Card.

Eyeshield. Gallenkamp have introduced an eyeshield to be used as protection against UV light. The lenses, shade 3 BS 679, are tinted and screen out all wavelengths down to 200 nm. Made of nylon, the eyeshield has hinged sidepieces and earbows.
Circle No. 101 on Reader Enquiry Card.



Pocket digital thermometer. Forma Scientific has introduced a new pocket digital thermometer designed for checking temperatures in ultra-low-temperature freezers, blook bank red cell and plasma freezers, laboratory refrigerators, environmental chambers, incubators and other laboratory equipment. Features of this new thermometer include: temperature range from −90.0°C to +60.0°C; digital readout to within 0.1°C; quick-response platinum probe; battery-saving liquid crystal display; quick disconnect 6 ft lead wire for use with multiple probes; finger touch on/off control.
Circle No. 102 on Reader Enquiry Card.

Biological safety cabinet. Nuaire. The Labgard class II, type 'B' biological safety cabinet has been introduced by Nuaire. The type 'B' cabinet has a vertical sliding sash and is designed to maintain an inward airflow of 100 LFPM at a work opening of 8 inches with an average downward vertical air velocity of 50 LFPM. The design requires separate exhausting of 70% of the air flowing through the work area and recirculates 30% through the HEPA filtration system. The cabinet is suitable, with separate exhaust system, for work with dilute preparations of chemical carcinogens.
Circle No. 103 on Reader Enquiry Card.

Asbestos-free insulation for laboratories. Lab Safety Supply. A new publication, entitled *High Temperature Materials for the Laboratory,* provides information on asbestos substitutes such as ceramic and high temperature synthetic fibres. It provides detailed physical and chemical properties of these materials and suggested laboratory uses. In addition, it discusses former uses for asbestos, its health hazards and current regulation. Also included is information about non-asbestos laboratory products made with these materials. These include gloves, tapes, ceramic centred wire gauze, hot pads, filter media and high temperature insulation. To obtain a free copy, write to: Lab Safety Supply Company, P.O. Box 1368, Janesville, WI 53545.

APPOINTMENTS VACANT

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

RESEARCH FELLOW

A research position is available in the Department of Structural Biology. Applicants should be familiar with the techniques used in electron microscopy and histochemistry. While the position is post-doctoral, applications without a PhD but with appropriate experience will be considered.

Appointment will be for three years commencing as soon as possible. Emoluments range £5,073 to £5,380 (under review). Details from the Establishment Officer, St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. 3398(A)

THE UNIVERSITY OF MANCHESTER

LECTURER IN BIOCHEMISTRY

Applications invited from post-doctoral candidates with research experience in any branch of biochemistry for this post in the Department of Obstetrics and Gynaecology, at St. Mary's Hospital.

Salary range p.a.: £4,333 to £8,992. Superannuation. Particulars and application forms (returnable by December 1st) from the Reigstrar, The University, Manchester, M13 9PL. Quote ref 212/79.

Requests for specific details about laboratory facilities and research activities should be addressed to Dr W.G. Bardsley, Department of Obstetrics and Gynaecology, St. Mary's Hospital, Manchester, M13 0JH. 3296(A)

PRESIDENT

University Corporation for Atmospheric Research (UCAR)

Boulder, Colorado

The Search Committee of the UCAR Board of Trustees invites nominations and applications for the President and Chief Executive Officer of UCAR. The Board of Trustees expects to fill the position promptly and seeks to have the individual in office no later than 1 July 1980.

UCAR is a private, nonprofit consortium of 44 U.S. and 2 Canadian institutions with graduate programs in the atmospheric sciences and related fields. UCAR's major activities consist of overseeing the programs of the National Center for Atmospheric Research (NCAR) In Boulder, Colorado and managing its operation; where appropriate, advocacy of the atmospheric sciences; the planning and conduct of special, cooperative atmospheric research programs; and fostering atmospheric research in the national interest.

To be considered for the UCAR presidency, a person should have demonstrated imaginative scientific leadership and sound management ability. A complete description of the duties and responsibilities of the President and qualifications for the candidates may be obtained by writing to Dr Gordon (address listed below). Applications and nominations, which must be postmarked no later than 1 November 1979, should be addressed to:

Dr. William E. Gordon
Chairman, Search Committee
UCAR
P.O. Box 3618
Boulder, Colorado 80307

UCAR IS AN EQUAL OPPORTUNITY, AFFIRMATIVE ACTION EMPLOYER

ROTHAMSTED EXPERIMENTAL STATION
Harpenden, Herts. AL5 2JQ

SCIENTIFIC OFFICER

required in Biochemistry Department to take charge of new glasshouse and controlled environment facilities and the provision of plant material for biochemical experiments. Previous experience essential, particularly in the handling of cereals and legumes.

Qualifications: Degree, HNC or equivalent qualification in a biological science, and relevant experience.

Appointment in grade of Scientific Officer (£3,289 to £5,085; £3,591 to £5,486 from 1.1.80). Starting salary according to qualifications and experience. Non-contributory superannuation.

Applications, giving names and addresses of two referees and quoting Ref.408 to the Secretary by 18th October, 1979. Further details on request. 3359(A)

UNIVERSITY OF NEWCASTLE UPON TYNE AND NEWCASTLE AREA HEALTH AUTHORITY
(Teaching)

CHAIR OF EXPERIMENTAL NEUROLOGY in the

DEPARTMENT OF NEUROLOGY

Applications are invited for the Chair of Experimental Neurology, which is endowed by the National Fund for Research into Crippling Diseases. Medically qualified applicants should hold a higher medical degree and have extensive research experience in adult or paediatric neurology or in neuropathology or in related disciplines, preferably of particular relevance to neuromuscular disease. Suitably qualified scientists without a medical qualification should have considerable experience in any branch of applied neurobiology which has a bearing upon neuromuscular function in man and animals and in health and disease. The appointment will take effect from 1st March 1980 or as soon as possible thereafter.

The successful candidate, if a registered medical practitioner, will be accorded Honorary Consultant status with the Newcastle A.H.A. (T). Salary in accordance with the Professorial (Clinical Consultant) or Professorial (Non-Clinical) scales, with membership of the appropriate University superannuation scheme.

Further particulars may be obtained from the Senior Assistant Registrar, The Medical School, University of Newcastle upon Tyne, Queen Victoria Road, Newcastle upon Tyne, NE1 7RU, with whom applications (15 copies) giving the names of not more than three referees, must be lodged not later than 31st October, 1979.
(Applicants from outside the British Isles may submit one copy only). 3400(A)

THE ROYAL MARSDEN HOSPITAL
Fulham Road, London SW3

BASIC GRADE PHYSICIST

Salary scale: £3,840 to £5,946 p.a. according to qualifications and experience. (Salary scale from 1.1.80 £4,161 to £6,429 p.a.)

Applications are invited from graduates and post graduates holding a good honours degree in physics who have an interest in radiotherapy physics. The successful applicant will be responsible for assisting with treatment planning using a PDP8 computer and will be closely involved with techniques and measurements on three Cobalt treatment units, a 10 MeV linear accelerator and a 300 KV X-Ray unit. It would be advantageous for applicants to have had some experience in radiation physics and computer programming.

Application Forms and Job description from: Miss E.M. Bewley, Group Personnel Officer (tel: 01.352.8171 Ext 446)

Closing date: 19th October 1979.
3406(A)

UNIVERSITY OF RHODESIA

CHAIR OF CHEMISTRY

Applications are invited for the post of Professor and Head of the Department of Chemistry. The Chair may be filled from any branch of Chemistry excepting Biochemistry.

Qualifications: Applicants should hold a doctorate, be experienced in research and teaching at university level, and have held a senior university appointment in Chemistry.

Salary scale: £9,162 × 345 to £10,872 p.a (approximate equivalent in £ sterling).

Conditions of service: Appointment will be on permanent, pensionable terms and these include: family passages and allowance towards transport of effects installation loan of up to half of one year' salary if required; unfurnished University accommodation guaranteed for a period o at least three years for persons recruited from outside Zimbabwe Rhodesia sabbatical leave and biennial visits with travel allowances; superannuation and medical aid schemes.

Applications (6 copies) giving full detail of personal particulars, qualifications experience, research, publications together with the names and addresses o three referees, should be sent to th Appointments Officer (Staff), University of Rhodesia, P.O. Box MP.167, Moun Pleasant, Salisbury, Zimbabwe-Rhodesia Overseas applicants should send a additional copy to the Association o Commonwealth Universities (Appts), 3 Gordon Square, London WC1H 0PF Further particulars may be obtained from either of the above.

Closing date for receipt of application 15 November 1979.

Note: British subjects considerin applying for posts in Zimbabwe-Rhodesi are urged to consult the Foreign an Commonwealth Office (tel: 01-233 4995) o their nearest British Consular Office.
3410(A)

VIROLOGIST
Assistant Professor

Two-year appointment with the possibility of tenure track. Salary commensurate with experience. To teach 2 half year lecture courses in Virology at the third and fourth year levels plus 1 half year Virology techniques laboratory. The candidate should have a PhD, some post-doctoral experience and be capable of developing a research program in Virology.

Excellent research facilities including Tissue Culture, Radioisotope and Biohazard containment laboratories are available.

The position is to start January 1, 1980, or as soon as a suitable candidate can be found.

Curriculum Vitae with names of 3 referees should be sent not later than December 15, 1979 to:

UNIVERSITY OF BRISTOL
CHAIR IN VETERINARY MEDICINE

The University invites applications for appointment to the Chair in Veterinary Medicine which will become vacant on 1st August 1980, following the retirement of Professor C.S.G. Grunsell.

Candidates, who must have a veterinary qualification, are invited to submit applications, including the names of three referees, not later than 30th November 1979.

Further particulars of the appointment may be obtained from the Registrar and Secretary of the University, Senate House, Bristol BS8 1TH. 3291(A)

MEDICAL RESEARCH COUNCIL
National Institute for Medical Research
LABORATORY OF DEVELOPMENTAL BIOCHEMISTRY

Applications are invited from

POSTDOCTORAL SCIENTISTS

for a position to join a group working with Dr J.R. Tata in the area of regulation of gene expression during development. The post is particularly suitable for a scientist interested in applying techniques of recombinant DNA to questions concerning hormone action and genomic organisation and transcription.

The appointment will be for up to three years and will be in the present salary range £4,940 to £6,627 per annum plus £502 p.a. London Allowance; superannuation provision.

Applications, giving a full curriculum vitae, research experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, London NW7 1AA before 15th November 1979 quoting reference DB.1. 3408(A)

CSIRO AUSTRALIA

Post doctoral Research Fellow
Centre for Animal Research and Development Bogor Indonesia

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research scientists — located in Divisions and Sections throughout Australia.

Field: Poultry Research

Duties: An experienced poultry research scientist is required to lead a research programme on Chicken Management and Nutrition at the Centre for Animal Research and Development in Indonesia. The aim is to develop appropriate management and feeding systems for both the large and small scale Indonesian poultry producer. The primary research effort will be directed to improving the efficiency of utilization of indigenous feedstuffs for chicken meat and eggs. The appointee will be expected to work closely with scientists working in an allied Duck Research Programme.

The centre has excellent facilities and staff for nutritional studies with chickens and there is a modern analytical laboratory and veterinary section to provide back-up service. Existing studies have focused on the evaluation of local feedstuffs and development of new feed resources. The new appointee will be expected to further the research in these areas, and to consider the general problems of management of small chicken flocks at the village level.

Qualifications: PhD and wide experience in the field of poultry research with an understanding of poultry nutritional experimentation. Experience in a tropical developing country an advantage. The training of Indonesian scientists will be an important responsibility and the successful applicant will be expected to show an interest and aptitude in this area.

Salary: Senior Research Scientists/Principal Research Scientist: $A20,198 — $A27,212 pa.

Tenure: Subject to negotiation, but a minimum of 3-4 years is envisaged. The appointee may be offered an indefinite appointment within CSIRO.

Conditions: Overseas conditions of service apply with respect to housing and allowances. As training of local staff is an integral part of the duties, it is essential that the successful applicant attain a degree of fluency in Indonesian language. To this end, a language course will be arranged.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 1000/050 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 6th November 1979

Applications in U.S.A. and Canada should be sent to:— The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3413(A)

Scientist

required to work on

Motion Sickness

at the Institute of Naval Medicine, Alverstoke, Hants, with support administered by the MEDICAL RESEARCH COUNCIL in a 3 year project. The appointee will be of post-doctoral status preferably with some experience in physiology and/or pharmacology. Medical qualifications and/or experience of working with human subjects advantageous.

Salary according to qualifications, experience and age, in the range: £5,200 to £6,930.

Further particulars from the Assistant Secretary, Royal Naval Personnel Research Committee, Room 407, First Avenue House, 40-48 High Holborn, London WC1V 6HE. 3381(A)

MRC
Medical Research Council

TECHNICAL OFFICER (COMPUTER APPLICATIONS)

Applied Physics Division

MATHEMATICS SECTION

The successful candidate will join a team in the Mathematics Section whose work covers a range of research areas in addition to providing a mathematical service within CERL. He/she will work closely with Research Officers engaged on a number of problems for which numerical and computation solution plays a large and important role. In addition he/she would contribute to the mathematical and computational service provided by the Section.

Applicants should ideally possess an HNC or equivalent qualification and at least two years experience of computer programming. The duties of the post require ideally a good understanding of mathematics and numerical analysis, together with a knowledge of a range of computer languages and modern programming techniques.

The appointment will be made within a salary range of £5200-£7630.

The Laboratories are situated in a pleasant part of Surrey and offer attractive Conditions of Service, and facilities for the total of 800 Research and Support Staff engaged in a broad spectrum of research into the materials, technologies and plant performance problems of the Central Electricity Generating Board.

Application forms are obtainable from the Head of Personnel Development & Services, Central Electricity Research Laboratories, Kelvin Avenue, Leatherhead, Surrey KT22 7SE or telephone Leatherhead 74488 Ext. 363, quoting reference number **RL/37/N** Closing date is: **Friday 19th October 1979.**

CENTRAL ELECTRICITY RESEARCH LABORATORIES

3375(A)

ROYAL FREE HOSPITAL

KATHARINE DORMANDY HAEMOPHILIA CENTRE & HAEMOSTASIS UNIT

Pond Street, London NW3 2QG

POST-DOCTORAL BIOCHEMIST

A position is available now to join a team working on the interaction of blood coagulation factors. The work involves purification to homogeneity of human blood coagulation proteins VIII, IX and X from normal and haemophilic blood. The proteins will be specifically labelled so that binding to platelets and activation can be followed simultaneously by tracer techniques. The study is supported by the MRC and represents a new approach to the biochemical lesion in haemophilia.

The Haemostatis Unit is housed on two floors of the newly-built Clinical Sciences Block of the Royal Free Hospital School of Medicine. The appointment is for 3 years, salary 1A.

Further details may be obtained from Dr E.G.D. Tuddenham at the above ess, Tel. No. 01 794 0500, Ext. 3806, to n curriculum vitae and names of three es should be sent by those applying post. 3374(A)

THE HARVARD SCHOOL OF PUBLIC HEALTH

is seeking an outstanding scholar in the population sciences to fill the newly created

CLARENCE JAMES GAMBLE PROFESSORSHIP

In addition, the incumbent will be the Chairperson of the Department of Population Sciences. According to the terms of the gift, the incumbent should be a person highly qualified and involved in the development of programs which have relevance for human population control and/or the investigation of social, cultural, ethnic, religious, economic or other factors which influence the relationship between human populations and resources. The Search Committee is particularly anxious to fill the Chair with an individual having a broad outlook on the role of population sciences and problems of population control. Women and members of minority groups are especially invited to apply.

Qualified individuals are invited to apply by sending a current curriculum vitae and the names of five references to:

M. Zelen, Chairman, Gamble Search Committee, Department of Biostatistics, Harvard School of Public Health, 677 Huntington Avenue, Boston, MA 02115. Harvard University is an Equal Opportunity Employer with an Affirmative Action program. W409(A)

POSTDOCTORAL

to join small group working on regulation of transcription and translation during spermatogenesis. Experience in nucleic acid or protein chemistry useful. Contact: Dr N Hecht, Dept of Biology, Tufts University, Medford, Mass. 02155.

he University invites applications for pointment to the Chair in Veterinary irgery which will become vacant on 1st nuary 1980, following the retirement of ofessor G. Arthur.

andidates, who must have a veterinary alification, are invited to submit plications, including the names of three erees, not later than 30th November 79.

rther particulars of the appointment ay be obtained from the Registrar and cretary of the Univesity, Senate House, istol BS8 1TH. 3290(A)

UNIVERSITY OF SURREY

EPARTMENT OF METALLURGY ND MATERIALS TECHNOLOGY

plications are invited for the post of dland Research Fellow tenable in the partment of Metallurgy and Materials chnology at the University of Surrey.

he research investigations will relate sely to the new product and technology grammes of Redland Ltd., a Company h world wide interests in building terials and related products. The Fellow carries out a number of subsidiary estigations requested by the Company's earch and Development Centre. The t affords an excellent opportunity for incumbent to familiarize himself with ustrial research and to make the nsition from academic to the industrial ironment.

pplicants should have a PhD or ivalent experience in some area of erial science, or solid state chemistry. ference may be given to candidates with rests or experience in silicate chemistry, land Cement and ceramics. In view of nature of the appointment, candidates ing the ability to formulate new erimental approaches to unresolved blems would be preferred. The Fellow ointed will undertake research in erials of interest in construction and ding and the main concern will be with perty structure relationships of interest eveloping new or improved materials.

he appointment would be made for two s and can be renewable.

emuneration will depend on age and rience and will be in the range £4,232 to 76 (under review), on scales related to University lecturer scales.

lications, from men and women, in the n of a curriculum vitae, with the names addresses of three referees, should be to: Professor J. E. Bailey, Department letallurgy and Materials Technology, ersity of Surrey, Guildford, Surrey 5XH. 3399(A)

The following Scientific vacancies exist in the Gwynedd Division of the Welsh Water Authority:—

TECHNICAL ASSISTANT (DATA) Reference 6SO17

Grade 4 (£4,887 – £5,235)

Applications are invited from persons either with a qualification in statistics and/or computer application or a qualification in chemistry and a special interest in statistics or data processing.

The post will be in the Divisional Scientists Department and will be based for several months at Caernarfon before the department moves to new offices at Bangor.

The work will involve data processing of treatment and pollution control information, both manually and by computer, statistical analysis and some mathematical modelling.

TECHNICIANS—2 Posts—Reference: 6SO37/6SO38

Grade 2 (£3,717 – £4,125)

Applications are invited for two posts within the Divisional Scientist Department. The work will involve routine sampling of natural waters (inland and tidal) and effluents and the investigation of pollution problems.

A qualification in chemistry or biology or a related subject would be an advantage. Previous experience would be an advantage but not essential. Candidates must hold a valid driving licence.

One post will be based at an Area Operations Office at Llandudno Junction (Ref: 6SO37) and the other post will be based at Dolgellau (Ref: 63038).

The Terms and Conditions of employment for all posts are as laid down by the National Joint Council for Water Service Staffs.

Application forms may be returned from the undernamed, the relevant reference numbers should be quoted in all cases.

Personnel Officer (Gwynedd),
Welsh Water Authority,
Bron Castell,
High Street,
BANGOR.

Tele: Bangor (0248) 52881 Extn: 51 or 52

Closing date for all posts: 19 October, 1979.

WELSH WATER AUTHORITY
AWDURDOD DWR CYMRU

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

POST DOCTORAL RESEARCH FELLOW

Applications are invited for a post doctoral research post (MRC funded) to study the regulation of the synthesis of anaerobic enzymes in *Escherichia coli*. Ideally the successful candidate will have had some previous experience of the techniques of DNA sequencing and/or *in vitro* protein synthesis.

The appointment is tenable for one year initially, with the possibility of extension for a further two years at a starting salary of up to £5,193 (under review) depending upon experience.

Informal enquiries may be made to Dr B A Haddock, Department of Biochemistry, University of Dundee, Dundee DD1 4HN (telephone 0382 23181 Ext 551).

Applications including curriculum vitae and the names and addresses of two referees should be sent to The Secretary, The University, Dundee DD1 4HN quoting Reference EST/84/79J as soon as possible.

3355(A)

CENTRAL PUBLIC HEALTH LABORATORY

DIVISION OF ENTERIC PATHOGENS

MEDICAL LABORATORY SCIENTIFIC OFFICER

The post is in the phage-typing and drug resistance unit. The successful applicant will assist in the routine work of the unit but will be expected to participate in the research programme and would be encouraged to work for higher qualifications such as a higher degree or FIMLS by thesis as appropriate.

The Division is the National Reference Centre for *Salmonella, Shigella* and *Escherichia coli*. The World Health Organisation Collaborative Centre for Phage-typing and Drug Resistance of Enterobacteria is located in the Division.

Suitable qualifications would be a relevant science degree, HNC or AILMS with experience in Microbiology.

Applications to: Personnel Officer, Central Public Health Laboratory, Colindale Avenue, Colindale, NW9. Tel: 01 205 7041. 3347(A)

WORCESTER COLLEGE OF HIGHER EDUCATION

County Council of Hereford and Worcester

Appointment of Lecturer II in Human Physiology

Applications are invited from candidates with appropriate first degree and higher research degree to lecture in Human Physiology in the B.A. (Hons.) in Combined Studies and B.Ed.(Hons.) Programmes. The appointment will be made from 1st January 1980 or as soon thereafter as possible.

The successful candidate must have particular interest in the physiology of nutrition and exercise, and will be expected to play a leading role in the development of courses in Human and Social Biology.

The salary will be at the appropriate point on the Lecturer Grade II Scale, £4,542 to £7,221.

Application forms and further particulars may be obtained from The Principal, Worcester College of Higher Education, Henwick Grove, Worcester, to whom completed application form should be returned as soon as possible.

3391(A)

Cardiovascular Pharmcologists

Greenford, Middx.

With the appointment of Dr. D. W. Straughan, B.Sc., Ph.D., M.B., B.S., L.R.C.P., M.R.C.S., as Director of Pharmacology, the Greenford Division of Glaxo Group Research Ltd. is seeking two young and enthusiastic pharmacologists to join the Cardiovascular Section of the Pharmacology Department.

While there is some flexibility regarding the precise responsibilities attaching to the two posts, it is envisaged that one position will be filled by a recently qualified graduate with a good honours degree who now wishes to develop an interest in cardiovascular research. The second post will be suitable for a person with previous research experience relevant to the development and evaluation of new compounds of potential value in the treatment of cardiovascular diseases. A sound knowledge of current concepts regarding the actions of drugs on receptors and the implications for drug design is considered essential.

We offer competitive salaries and excellent conditions of employment, including pension and bonus schemes, a subsidised cafeteria, and a sports and social club.

Please write, or telephone, for an application form to:— Mrs. C. A. Carter, Personnel Officer, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex. Tel: 01-422 3434, ext. 11. Ref. no. 282. 3412(A)

Glaxo Group Research Ltd.

SCOTTISH MARINE BIOLOGICAL ASSOCIATION

DUNSTAFFNAGE MARINE RESEARCH LABORATORY

nr. Oban, Argyll.

Applications are invited for the post of

DEPUTY DIRECTOR

at the Dunstaffnage Marine Research Laboratory.

The Dunstaffnage Laboratory is multidisciplinary, undertaking basic, strategic and applied research in coastal waters and the deep sea. Some postgraduate teaching is undertaken in conjunction with Stirling University. The staff number about 100 and in addition there are about 12 postgraduate students. The Laboratory, which is independent, is funded by a grant from the Natural Environment Research Council and by contract work, and has an annual budget of about £950,000.

Candidates will be expected to have an established reputation in marine science and an aptitude for laboratory administration. The post is graded at Senior Principal Scientific Officer level, and the appointee will be required to take part in the management of the research and administration of the Laboratory and deputise for the Director in his absence.

Application forms and further details may be obtained from the Administrative Officer, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. Closing date for receipt of application forms: 26 October, 1979.

3402(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

BIOCHEMISTRY RESEARCH DEMONSTRATORSHIP

Applications are invited for the post of

DEMONSTRATOR

in the Department of Biochemistry from candidates who possess, or have submitted for, a PhD in Biochemistry, for a period of up to three years, tenable from 1st January, 1980. Research projects currently in progress include membrane transport of nucleic acid precursors (Professor K. Burton), acquisition and modification of enzyme conformation, and immunochemistry of monocyte surface (Professor R.H. Paine), DNA repair and genetic recombination (Dr P.T. Emmerson), triglyceride and lipoprotein metabolism (Dr M.P. Rogers), enzymology of resistance to antibiotics (Dr R. Virden), lactose transport and bioenergetics (Dr I.C. West) and hormonal control of enzyme activity (Dr S.J. Yeaman). Duties will also include teaching (approximately 90 hours per year) by lectures, tutorials and practical classes.

Salary will be at an appropriate point on the Grade 1B (Bar) scale £3,775 to £5,488 per annum according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar (F.P.) The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (2 copies), giving the names and addresses of three referees, should be lodged as soon as possible.

3376(A)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE

DIAGNOSTIC RESEARCH UNIT

Applications are invited for the following posts:—

TWO EXPERIMENTAL OFFICERS

Funds are available for the above posts in the recently established Diagnostic Research Unit which is closely integrated with the Department of Medicine (Professor Ralph Wright). The objective is to develop original serological procedures for widespread diagnostic application in hospitals and biochemical and immunological laboratories. The appointees will be expected to use initiative but would receive general direction from the Senior Experimental Officer in the Unit. The work will require a broad knowledge of biochemical and immunological techniques. Preference will be given to post-doctoral biochemists/immunologists.

The appointments will be for one year initially but may be renewed on an annual basis.

Salaries within the scale £3,775 to £6,355 p.a.

For further details contact Dr F.G. Bull on Southampton 777222 ext. 3910 or 4299.

Applications giving details of qualifications and experience and the names of two referees should be sent to Mrs P. Vaughan-Smith, Staffing Section, The University, Southampton, SO9 5NH, as soon as possible. Please quote ref: 1097/A/N. 3356(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the Scho of Earth Sciences invites applications fo faculty position beginning Septemb 1980. Areas of interest include (but are n limited to) geochemical processes in t crust and mantle of the earth includi isotope geochemistry, thermodynami kinetics, element distribution and pha equilibria studies. Teaching responsibilit might include graduate and undergradu courses in geochemistry and igneo petrology. Level of appointment is ope but we are particularly interested in creative young person, with a we established record in research.

Applications should include (1) a resu of education, professional experience, a published research; (2) a brief statement plans for future research, and (3) the nam of 4 referees. Send to: Prof. J.G. Lio Department of Geology, Stanfo University, Stanford, CA 94305, December 1st, 1979. Stanford University an equal-opportunity/affirmative-acti employer. W329(A)

PAPUA NEW GUINEA INSTITUTE OF MEDICAL RESEARCH

Position Vacant

RESEARCH FELLOW IN IMMUNOLOGY

The Institute is a statutory body within Ministry of Health of the Government Papua New Guinea. It is involved in a w range of fundamental and applied resea related to the health of Papua N Guineans.

Location: Main complex situated Goroka, in the Eastern Highla Province, with a branch at Madang, an number of laboratories and field stati throughout the country.

Duties: To undertake research i immunological aspects of infecti diseases prevalent in Papua New Guine particular to participate in a mu disciplinary study of acute respirat infections. Other members of the resea team include an epidemiologist, a vi logist, a bacteriologist, a nutritionist an paediatrician. The successful applicant be expected to develop assays for detection of bcterial antigenaemia, an collaborate in vaccine trials, in additio other research activities arising out of applicant's own particular interests.

Qualifications: MD or PhD immunology or bacteriology, equivalent. Applicants with a Ma degree will be considered if their experi is particularly appropriate to the requ ments of the position.

Conditions of Service: Similar University of Papua New Guinea. Suit accommodation will be provided by Institute. For a contract appointme 3-year contract will be offered; recruit fares and expenses and leave fares e eighteen months will be paid.

Salary: Overseas salary payable w applicable (K10165 to K13725 plus annual gratuity of 24% for the first t years). (1K (kina) = 1.40 US$). Fo experienced senior applicant appoint at the level of Senior Research Fe (K15575 plus gratuity) would considered.

Inquiries and applications: Applicat should include a curriculum vitae, an names and addresses of at least referees, and be addressed to:

The Secretary, PNG Institut
Medical Research, P.O. Box

THE UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY

plications are invited for a post of

RESEARCH FELLOW

the Department of Biochemistry. The ject, under the supervision of Dr S.B. own and supported by the Nuffield undation, will involve studies on the chanisms of oxidative degradation of m and chlorophyll derivatives. The post be suitable either for an organic mist interested in acquiring experience a biochemical environment or, rnatively, for a biochemist with some npetence in organic chemical hniques. Previous experience with apyrroles would be an advantage but is essential. A PhD degree is required. appointment will be made for a fixed od of three years and it is hoped that the cessful candidate will be able to take up post as soon as possible.

tarting salary in the range £4,333 to 488 on the 1A scale for Research and alogous Staff (£4,333 to £7,521) (under ew) according to age, qualifications experience.

pplication forms and further iculars may be obtained from the istrar, The University, Leeds LS2 9JT, ting reference number 83/25. Closing for applications 19 October 1979.
3319(A)

Research Associate Post in the Theory of Continuum States of Atoms and Molecules

The Computational Science Group of the Daresbury Laboratory is currently engaged in a research project on the continuum states of atoms and molecules. The work is being carried out in collaboration with a number of University groups.

A post attached to this project is offered for three years as a Research Associate; it is superannuable and in the salary range £4545 to £7712 per annum depending on age, qualifications and experience. Candidates will be expected to have a good knowledge of current theory of atomic and molecular processes and to have had relevant experience in the implementation of these theoretical models on a computer. The laboratory has powerful computing facilities available including IBM 370/165 and CRAY-1 computers on-site, and a link to two IBM 360/195 computers at the SRC Rutherford laboratory.

Applicants, of either sex, should preferably have or expect to obtain a PhD in Physics/Chemistry and should write (or telephone Warrington 65000, Ext. 407) for an application form quoting reference DL/705/CB to:—

The Personnel Officer
DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

Closing date — November 16th 1979. 3387(A)

POSTDOCTORAL RESEARCH FELLOW IN GEOPHYSICS

The Division of Geological and Planetary Sciences at the California Institute of Technology expects to offer a Research Fellow appointment in the area of solid-state high pressure geophysics and/or descriptions of the high pressure phenomena associated with impact cratering on planetary surfaces.

Research fellowships in geology, general geophysics, geochemistry, geobiology, and planetary science are also available from time to time. Interested persons are asked to contact Dr Barclay Kamb, Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125. An Equal Opportunity/Affirmative Action Employer. W411(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

RESEARCH TECHNICIAN

required for 3 year research programme in the Child Health Department. Duties involve programmes in infant nutrition, biochemical genetics, endocrinology and lipid metabolism in children. H.N.C. or degree in biochemistry or related subject required.

Emoluments range £3,700 to £4,584 plus London allowance £275 p.a. (under review). Enquiries to Dr N. McIntosh (01-672-1255 ext 4170).

Application forms from Establishment Officer, St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. 3379(A)

RICE UNIVERSITY
Announces the opening of a

CENTER FOR SPACE PHYSICS

Scientists with experience in theoretical or experimental space physics are invited to apply for continuing, full-time research staff positions at the level of Assistant, Associate, or Senior Research Scientist. (These three levels are roughly parallel to the three academic faculty ranks, except that they do not carry tenure and must be fully funded from external research grants and contracts.)

It is anticipated that the Center will promote several subdisciplines of Space Physics research, including computer simulation of magnetosphere studies. The specific area of emphasis will be determined by the individual interests of the research staff and by the nature of the grant/contract support that they are able to generate.

Applications and resumes should be addressed to Prof. A.J. Dessler (Chairman), Dept. of Space Physics and Astronomy, Rice University, Houston, TX 77001. The University is an equal opportunity/affirmative action employer.
W415(A)

SUPRA REGIONAL PROTEIN REFERENCE UNIT, CARDIFF

Applications are invited for the post of

RESEARCH ASSISTANT

to work on the development and assessment of immune complex assays in clinical chemistry. This project is supported by the Welsh Office scheme for the development of Health and Social research. The post will be for one year in the first instance, but renewal for the second year may be possible.

Candidates should have a degree in Biochemistry, Biological Sciences or equivalent and salary scales will be according to qualification and experience, but will be on the Whitley Scale for probationary grade hospital Biochemists.

Further details of the project and the post can be obtained from:
Dr. R. Fifield, Protein Reference Unit,
Cardiff Royal Infirmary, Tel: 0222 492233 Ext. 559

Application forms are obtainable from:
Assistant Unit Administrator, Cardiff Royal Infirmary,
Newport Road, Cardiff. Tel: 0222 492233.
Closing date: 22nd October, 1979 3373(A)

Universiteit van Amsterdam

The Department of Physics and Astronomy
of the University of Amsterdam
has an opening for the position of

lector* (m/f) in theoretical physics

This is a new position created to promote and stimulate co-operation in theoretical and experimental high energy physics. The appointed lector shall be a joint member of the Theoretical Institute and the High Energy Institute of the University. The latter is a participant in the National Institute for Nuclear and High Energy Physics (NIKHEF).

The field of research of the Theoretical Institute includes the theory of elementary particles, statistical mechanics, relativistic kinetic gas theory, and intermolecular interactions. The research of the High Energy Institute is in the area of bubble chamber experiments and counter experiments that are carried out with accelerators, in particular those at CERN, Geneva.

The functions of the lector shall be the following. The performance, stimulation and guidance of research in theoretical physics with emphasis on the forging of a strong bond between the two institutes. The giving of lectures in theoretical physics, in particular high energy physics. The guidance of graduate students in theoretical and high energy experimental physics.

People interested in this position are asked to submit a written application before December 1, 1979 including a curriculum vitae, a list of publications, and the names and addresses of a few references who can provide information concerning scientific and personal qualifications.

Suggestions of names of candidates for this function should be submitted before November 1, 1979.

Suggestions and applications should be sent to the chairman of the appointment committee,

Dr. T. de Jong,
Bureau Subfaculteit Natuur- en Sterrenkunde,
Nieuwe Achtergracht 170,
1018 WV Amsterdam, The Netherlands.

* In the Dutch academic system, the highest ranking faculty positions are professor and lector.

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for a postdoctoral research associateship to work on the characteristics and regulation of catecholamine receptors in the central nervous system. Experience in receptor labelling techniques and cyclic nucleotide metabolism would be advantageous but not essential. Applicants should be recent PhD graduates or have up to three years postdoctoral experience. The post is for two years and the salary will be in the Range 1A (£4,333 to £7,521) depending upon age and experience.

Applications giving details of qualifications, research experience and the names of two academic referees should be sent to Dr S.R. Nahorski, Department of Pharmacology and Therapeutics, School of Medicine, Medical Sciences Building, University of Leicester, University Road, Leicester. LE1 7RH (Tel: 0533 551234, Ext. 361). 3358(A)

INTERNATIONAL CENTER FOR TROPICAL AGRICULTURE AGRICULTURAL SCIENCES WRITER/EDITOR

The International Center for Tropical Agriculture (CIAT) generates and transfers technology for improved production of certain basic food crops. CIAT is seeking an agricultural science writer/technical editor to work with its research staff in developing articles and publications on its work. Audiences include agricultural scientists, national planners and policy makers in developing countries and various groups in developed countries working to improve food production in the Tropics. Some technical editing is also required.

Candidates must have proved ability to supervise editorial personnel. A minimum of three years of experience in agricultural science writing and editing is desired; message production experience in other media would be helpful. An MS or PhD in some agricultural field is preferred and fluency in Spanish is desirable. The position is at CIAT headquarters, Cali, Colombia.

Send letters of application, with curriculum vitae and three references, to Dr. Alexander Grobman, Director for International Cooperation, Centro Internacional de Agricultura Tropical, Apartado Aéreo 6713, Cali, Colombia. Closing date is November 15, 1979.

Post-doctoral Molecular Biologis Biochemist required for a research tea investigating the molecular basis of ment retardation. Experience in nuclear aci and protein synthesis essential. Tl position is tenable for up to 5 yea commencing January 1980. Starting sala will be up to £5,199, plus £740 Lond allowance, on range 1A, depending on a and experience.

Apply with c.v. and names of thr referees to Dr. L. Lim, Institute Neurology, 33 John's Mews, Lond WC1N 2NS (Tel: 01-242 4063). 3397(A)

UNIVERSITY OF EAST ANGLIA, NORWICI

SCHOOL OF CHEMICAL SCIENCES

Electron Energy Loss Spectroscopy of Adsorbed Molecules

Applications are invited for an

SRC POSTDOCTORAL RESEARCH

appointment to work with this new hig sensitive technique of vibratio spectroscopy in order to study the struct of chemisorbed species on single-cry planes of metals. Equipment for research will shortly be installed and combine electron energy loss measu ments with LEED and Au spectroscopy. Experience in application of electron spectrosco techniques in surface chemical phy would be of advantage.

The project is a joint one between E Anglia and Queen Mary College, Lon (Professor J. Pritchard) but the succes applicant will be based at Norwich. post is tenable for a period close to 3 ye depending on the initial salary which wi near point 3 of the RA1A scale (£4,776

Applicants should write to Professor Sheppard, F.R.S., or Dr M.A. Chest School of Chemical Sciences, Universit East Anglia, Norwich NR4 7TJ, enclos a curriculum vitae and the names addresses of two referees.

Director of Biology

G. D. Searle is a leading international pharmaceutical company with its main U.K. headquarters and research facilities at High Wycombe in Buckinghamshire.

Applications are invited for the position of Director of Biology from persons with qualifications and research experience in a Biological Science, preferably Pharmacology. This position reports to the Director of Research.

Responsibilities include directing the efforts of a number of groups of biological scientists working principally in the area of infectious diseases, immunology and tumour biology. In addition to drug testing programmes, studies on the mechanism of action of therapeutic agents and on the basic biology of the diseases are undertaken. The successful applicant must therefore have a broad view of biology and medicine, whilst being able to direct in depth studies in particular areas. The responsibilities also include management of the animal facilities, so direct experience is essential. Experience in supervision and administration of other licencees will be advantageous.

The groups within the Research Department are organised to encourage an interdisciplinary approach to most studies and past experience of this aspect within the Pharmaceutical Industry will be a strong recommendation. In addition evidence of managerial experience will be required.

This is a senior position, carrying a place on the Management Group of the Research Department, and the salary, which is negotiable, will reflect this seniority.

The benefits accompanying this post include: company car, relocation assistance, life insurance, contributory pension fund, private medical scheme, and sports and social club.

Applications should be addressed to Mr G. Jenkins, Personnel Manager, Searle Research & Development, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks (Tel. High Wycombe 21124, ext. 3374).

ECOLOGY AND ANIMAL BEHAVIOUR

The Biology Department of McGill University offers two positions with a diverse and active group of terrestrial and aquatic ecologists at the level of assistant professor (both tenure stream), beginning in September 1980.

Send a curriculum vitae, a statement of research and teaching interests, and the names, addresses and telephone numbers of three potential referees to Dr. F. H. Rigler, Chairman, Department of Biology, McGill University, 1205 Avenue Docteur Penfield, Montreal, Quebec, Canada, H3A 1B1. Competition closes on December 15, 1979. W416(A)

UNIVERSITY OF CAMBRIDGE

RESEARCH ASSISTANT (Physics/Electronic Engineering)

A physicist or electronic engineer with graduate or equivalent qualification is required to join a team engaged in the development and application of ion-probe mass spectrometry. Experience with computer-based measuring systems is highly desirable and some familiarity with ion or electron optics and ultra-high vacuum equipment would be an advantage. The successful applicant may expect to gain experience of a wide range of experimental techniques.

The post is tenable until Feb 1982 with a starting salary in the range £4,055 to £4,622 per annum, depending on age and experience.

Applications, stating qualifications & experience, should be sent to Dr J.V.P. Long, N.E.R.C. Ion-Probe Unit, c/o Department of Geodesy & Geophysics, Madingley Rise, Cambridge, from whom further information may be obtained.

3363(A)

NEW ZEALAND

CENTRAL INSTITUTE OF TECHNOLOGY

SCHOOL OF PHARMACY

The Council of the Central Institute of Technology wishes to make appointments in the following subject areas and invites applications from suitably qualified persons:

(1) *Pharmaceutical Chemistry:* A person suitably experienced in the field of medicinal chemistry. Experience in teaching would be desirable but not essential. Applicants with qualifications and interests in closely related areas will be considered.

(2) *Pharmaceutics:* A person experienced in formulation technology. A particular interest in microbiological aspects would be advantageous but not essential.

The above positions would suit graduates interested in taking responsibility for specific sections of the Diploma course which is of three years duration and leads to the basic registrable qualification for New Zealand pharmacists.

Assistance with fares and transfer of baggage may be available to the successful applicant.

It is anticipated that initial appointments will be made to one of the following scales, depending upon qualifications and experience:

Scale 2: NZ$10,928 to NZ$14,126

Scale 3: NZ$13,229 to NZ$15,401

For a particularly well qualified and experienced applicant:

Scale 4: NZ$14,989 to NZ$16,549

Salaries are at present under review and will rise when the review is completed.

For further information and application forms write to either:

The Chief Migration Officer
New Zealand House
Haymarket
LONDON SW1Y 4TQ

or

The New Zealand Embassy
37 Observatory Circle
NW
WASHINGTON, DC
20008

Applicants writing to London should quote vacancy number Imm 2/323/5 CIT/2 : to Washington CIT/2. 3368(A)

Earth Scientists

Geothermal Research

We have an unusual and interesting opportunity for someone to take responsibility for a project in Geothermal Research. Based at our Geophysics Research Branch in London, you will construct, assess and use a computer model for the calculation of the thermal history of sedimentary basins with particular reference to organic diagenesis. This key project provides the chance for a strongly innovating role.

To be able to contribute to this project, you will probably have 3-4 years' post Ph.D./M.Sc. experience in the earth sciences. A strong numerical background and the ability to use the computer in this work, including programme writing, are important. Essential qualities are the ability to initiate new ideas and the drive to develop and use them and present them to others.

Our current salary levels, together with non-contributory pension scheme, subsidised lunches and excellent sports and social facilities, now represent outstanding conditions of employment.

Please write, giving details of age, qualifications and experience, quoting reference U.716 to: Sue Bartholomeou, Central Recruitment, The British Petroleum Company Limited, Britannic House, Moor Lane, London EC2Y 9BU.

The appointment will be for 3 years and the successful applicant will be expected to take up his or her duties as soon as conveniently possible.

Salary: £4,333 to £5,777 p.a. on Range 1A. USS benefits.

Applications giving date of birth, curriculum vitae and the names of three referees should be sent to Mrs P. Vaughan-Smith, Staffing Section, The University, Southampton, SO9 5NH, as soon as possible quoting ref: 1099/R/Na

3328(A)

Innovative Bioscientists for Fermentation Development

The Fermentation Development Department of our Worthing site is concerned with the development of fermentation processes for the production of antibiotics and related substances. We now wish to recruit the following:

Microbiologist

The Strain Improvement Section requires an honours graduate in microbiology. A logical mind, coupled with an ability for systems innovation, is an essential prerequisite, and the successful candidate would also be expected to co-ordinate the activities of a small technical team.

Microbial Biochemist

The Biochemistry Section is involved in characterizing the critical events controlling the large scale production of antibiotics. Applicants should possess a good honours degree in biochemistry or microbiology, preferably with some post graduate experience. They should have an innovative approach combined with the flexibility of outlook necessary to deal with the varied problems arising from a complex bio-technological operation.

As well as a pleasant South Coast location Beecham offers a bracing scientific atmosphere.

Please write or telephone for an application form to:

Mr A D Caws, Senior Personnel Officer, Beecham Pharmaceuticals, Clarendon Road, Worthing, West Sussex, BN14 8QH. Telephone: (0903) 39900 Extension 233.

DEPARTMENT OF PHARMACOLOGY

RESEARCH ASSISTANT

pplications are invited for this post available from 1 November 1979 for two years with ossibility of renewal. Candidates (M.Sc., Ph.D, or MD) should be familiar with ochemical techniques, with experience in purification of proteins (including affinity romatography) and production of antibodies. The successful candidate will work within r hypertension research group. Knowledge of French would be an advantage but is not a quirement.

Salary within range of Sw. Frs. 27'700.--to Sw. Frs. 47'607.-- p.a.

Applicants should send a curriculum vitae and names of three referees to: Prof. G. ters, M.D., Institut de pharmacologie de l'Université de Lausanne, Rue du Bugnon 21, H-1011, *Lausanne*, (Switzerland)

W405(A)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for the post of

HEAD OF THE ANIMAL DIVISION

in succession to Dr. J.J. Bullen who will be retiring in September 1980. The primary responsibilities of the post are the organisation and supervision of the breeding of animals and of facilities for experimental work. Facilities for research are available and can be discussed with the candidates. Preference will be given to applicants with a veterinary qualification.

The post is equivalent to that of a Professor or Reader in a university and carries the corresponding salary.

Further details are available on request.

Applications, accompanied by the names of two referees, should be sent to the Director, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA, to arrive not later than 30 November, 1979.

3361(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Soils
Adelaide SA

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research scientists — located in Divisions and Sections throughout Australia.

Field: Isotope Hydrology

General: The Division undertakes research on a wide range of subjects within the field of soil science aimed at conserving and managing Australia's soil and water resources for agricultural, urban and recreational use. The hydrology program is one of a number being pursued in Adelaide. It is currently concerned with the use of natural tracers for the evaluation of hydrologic parameters in a range of natural systems. With support from the Engineering and Water Supply Department of South Australia and in collaboration with Flinders University, the Division is initiating a study of the water resources of the low rainfall areas of northern South Australia. The techniques of isotope hydrology should make a unique contribution to an understanding of the hydrology of these and other arid areas.

Duties: To carry out laboratory and field studies on the variation of oxygen-18 and deuterium in soil profiles under arid conditions. Subsequently the appointee will be expected to examine other areas of arid zone hydrology.

Qualifications: A PhD or equivalent with experience in isotope hydrology together with the ability to apply mathematics to natural systems. As much if the work will be involved with the unsaturated zone, a knowledge of the principles of soil physics would also be an advantage.

Salary: Research Scientists: $A15,916 — $A19,509 pa.

Tenure: Two years.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 270/490 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 6th November 1979

Applications in U.S.A. and Canada should be sent to:— The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

3414(A)

BIRMINGHAM MATERNITY HOSPITAL

Central Birmingham Health District

BASIC GRADE CYTOGENETICIST

Applications are invited for this post from persons with a relevant science degree. Experience in human cytogenetics is desirable.

The successful applicant will work in the Cytogenetics Laboratory in the Infant Development Unit at Birmingham Maternity Hospital.

Further details and permission to visit the laboratory may be obtained from Mrs S.M. Bowser-Riley (021 472 1377 Ext. 157) Principal Cytogeneticist, Infant Development Unit, Birmingham Maternity Hospital, Birmingham B15 2TG.

Application forms available from Personnel Officer at the Maternity Hospital.

3392(A)

BIOLOGICAL SAFETY OFFICER

UNIVERSITY OF FLORIDA

This position requires a Master's Degree in an area of Biological or Basic Medical Sciences with a minimum of 3 years experience in biological safety. Experience should include basic scientific techniques and manipulations common to biomedical research. A technical knowledge in basic microbiology and biological safety techniques and practices, containment equipment, and engineering principles pertaining to the design and operation of biological and medical facility safeguards is also required.

Send complete resume with salary requirements and salary history by November 15, 1979 to:

Robert L. Willits
Administrative Employment Manager
Second Floor HUB
University of Florida
Gainesville, Florida 32611

EQUAL EMPLOYMENT OPPORTUNITY/
AFFIRMATIVE ACTION EMPLOYER

W414(A)

FELLOWSHIPS/ STUDENTSHIPS

UNIVERSITY OF KEELE

DEPARTMENT OF PHYSICS

RESEARCH FELLOWSHIP

Synchrotron Radiation Protein Crystallography

Applications are invited for a three year SRC supported Post Doctoral Fellowship commencing on 1st October or as soon as possible thereafter to work with Dr J.R. Helliwell on the x-ray crystallographic study of 6-phosphogluconate dehydrogenase from Bacillus stearothermophilus utilising the Synchrotron Radiation Source (SRS) presently under construction at Daresbury Laboratory as well as facilities within the Department. Initial experiments, prior to the opening of the SRS, will be performed at other synchrotron radiation facilities in Europe.

The successful applicant will also be involved in the setting up of the protein crystallography experimental apparatus at Daresbury. Experience in crystallography, X-ray scattering or synchrotron radiation advantageous but not essential.

Salary starts at point 3 of the research scale 1A £4,910 to £5,488. Further particulars and application forms from The Registrar, The University, Keele, Staffs., ST5 5BG to whom completed forms, as well as curriculum vitae and details of research experience, should be returned as soon as possible. 3383(E)

McMASTER UNIVERSITY

DEPARTMENT OF BIOCHEMISTRY

A POSTDOCTORAL FELLOWSHIP

is available in the area of mitochondrial biogenesis in mammalian cells with emphasis on genetics, proteins biosynthesis and membranes, with Dr K.B. Freeman.

The fellowship is valued at $12,200 per year, taxable and may be renewed for one year. For further information write to: Dr K.B. Freeman, Department of Biochemistry, McMaster University, 1200 Main Street West, Hamilton, Ontario L8S 4J9 Canada. W396(E)

-Unique Opportunity- STANFORD UNIVERSITY

NSF POSTDOCTORAL FELLOWSHIP in MOLECULAR BIOLOGY and COMPUTER SCIENCE

$14,000 per annum

Applicants should be familiar with the techniques of modern molecular biology and be interested in entering the field of computer science. Previous programming experience is useful but not essential. Responsibilities will include development and maintenance of a knowledge base of current laboratory techniques for use with an advanced model of automated experimental planning. One goal of this program is to train an individual for a career in computer science as applied to molecular biology and genetics. While the fellowship will be awarded through the Department of Computer Science, the fellow will interact regularly with research groups in the Departments of Biochemistry and Medicine.

Send resume and the names of three references to either:

Dr Douglas Brutlag, Department of Biochemistry or Dr L.H. Kedes, Department of Medicine, Stanford University, School of Medicine, Stanford, California 94305. Equal opportunity through affirmative action. W383(E)

Southampton THE UNIVERSITY

DEPARTMENT OF CHEMISTRY

Applications are invited for a CASE Studentship, co-sponsored by Bush, Boake, Allen Ltd. The project is concerned with Organometallic Complexes and Catalysed Reactions of Isoprene, and the successful candidate will be expected to register for a higher degree. Applicants should have at least a University Upper Second class degree.

Applications, including the names of two referees should be sent to: Professor R. Baker, Department of Chemistry, The University, Southampton SO9 5NH. 3384(F)

THE UNIVERSITY OF SYDNEY

F. H. LOXTON POSTGRADUATE STUDENTSHIPS

Applications are invited for the above studentships from male graduates who wish to undertake postgraduate research in the following areas:

AGRICULTURE CHEMICAL ENGINEERING

Areas of current interest in the Department of Chemical Engineering include: Biochemical Engineering, Computer-Aided Design, Computer Process Control, Distillation and Mass Transfer, Environmental Engineering, Minerals Processing, Particulate Solids Technology, Petroleum and Reservoir Engineering, Reaction Engineering, Renewable Energy Sources, Solar Energy, including fuel alcohol production and desalination technology, Solids and Particle Technology and Systems Engineering.

VETERINARY SCIENCE

General

The studentships are tenable for one year and may be renewed for up to three further years and are valued at $A4,200 per annum plus allowances. Further information is available from: The Registrar, the University of Sydney, NSW 2006, Australia, with whom applications close on 20 December, 1979. 3390(F)

The ISAAK WALTON KILLAM POSTDOCTORAL FELLOWSHIPS

1980-81

DALEHOUSIE UNIVERSITY

Value

Fellowships valued at $13,500 (1979-80), plus travel allowances, are tenable for one year at Dalhousie University in most fields of study. Application for extensions may be considered.

Qualification

applicants should have recently completed a PhD Degree at a recognized university, or expect to obtain a degree before taking up an award.

Application

Application forms may be obtained by writing to:

The Office of the Dean, Faculty of Graduate Studies, Dalhousie University, Halifax, Nova Scotia B3H 4H6

The closing date for receipt of applications is 15 December, 1979. W382(E)

ATHROFA GOGLEDD-DD CYMRU

THE NORTH E WALES INSTITUTE OF HIGHER EDUCATION

Kelsterton College, Connah's Quay, Deeside, Clwyd

SRC CASE STUDENTSHIPS

Applications are invited for a SRC CASE Studentship tenable immediately for work on the following project: "Radio-immunoassay of polyamines", in collaboration with Ortho Diagnostics, Ltd. Supervisors: Drs. J. C. Allen and C. J. Smith.

The co-operating body will supplement the SRC Studentship by £250 p.a. Applicants should possess or expect to obtain 1st or upper 2nd class Honours, and should write as soon as possible, with curriculum vitae, to the Institute Registrar, North E Wales Institute, Kelsterton College, Connah's Quay, Deeside, Clwyd CH5 4BR. 3395(F)

UNIVERSITY OF COLORADO

VISITING FELLOWSHIPS

For Research in Solid Earth and Atmospheric Science

One year awards offered by CIRES, a Research Institute sponsored by NOAA and the University of Colorado. Stipend is scaled to experience, and the program is open to scientists of all countries.

Applications for the 1980-81 academic year awards should be sent to The Director, CIRES Visiting Fellows Program, Campus Box 449, University of Colorado, Boulder, Colorado 80309 USA, before February 1, and should include names of three referees, a vitae and publications list, and a brief outline of the proposed research.

Affirmative Action Equal Opportunity, Section 540, Employer. W399(E)

ASSISTANTSHIPS

THE UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

GRADUATE TEACHING ASSISTANTSHIPS 1980/81

Academic Year

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc. and PhD Degrees in Chemistry. Excellent research facilities are available in all areas of modern Chemical Science, ranging from Bio-Inorganic Chemistry to Chemical Physics. For first year students the minimum stipend, including the summer research assistantship, is anticipated to be $8,000 per annum.

Students entering the programme with a Master's degree will receive a higher minimum stipend of $8,500 per annum. In addition, many special merit awards are made to those graduate teaching assistants who show excellence in the performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned:

Professor C.A. McDowell,
Department of Chemistry, The
University of British Columbia, 2075
Wesbrook Mall, Vancouver, B.C.
Canada, V6T 1W5 W400(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited from both

THEORETICIANS and OBSERVERS

for an SRC funded

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

tenable for 2 years from 1 January 1980 to work in Extragalactic Astronomy with the Cosmology group.

Initial salary in the range £4,333 to £4,910 on Range 1A plus superannuation.

Application (3 copies) naming three referees should be sent by 19 November 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. 3357(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited from a physicist or applied mathematician, with experience in advanced numerical methods, or in the use of large and mini computers for a

SENIOR RESEARCH ASSISTANTSHIP

tenable for three years from as soon as possible. He or she will be a member of the High Energy Cosmic Ray Group and will be responsible for the development of analysis methods for data from atmospheric Cerenkov radiation experiments in the U.S.A. Furthe information may be obtained from Dr K.E. Turver or Dr K.J. Orford (Te Durham 64971).

Salary in the range £4,333 to £7,521 pe annum plus superannuation.

Applications (3 copies) naming thre referees should be sent by 31 October 197 to the Registrar and Secretary, Scienc Laboratories, South Road, Durham DH 3LE. 3365(P)

GRANTS and SCHOLARSHIPS

THE ROYAL SOCIETY

THE RUTHERFORD SCHOLARSHIP

This award, for graduates of exceptiona promise and ability who are under 26 yea of age on 1 May 1980, is for experimenta research in any branch of the natura sciences, with a preference fo experimental physics if there are candidate of similar merit. It will be tenable for thre years, from 1 October 1980 or such othe date as may be arranged, in some part of t British Commonwealth other than that which the applicant graduated. The valu adjusted to meet the circumstances, will b £2,250 per annum on appointment (und review) if held in the United Kingdom, wi allowances for travel, university fees, etc. will not normally be awarded to a gradua who has already held a senior researc award.

Applictions should be made as follows

From university graduates *in the Unit Kingdom*: before 15 February 1980 forms obtainable from the Executi Secretary, The Royal Society, 6 Carlt House Terrace, London, SW1Y 5AG.

From university graduates *outside t United Kingdom*: through their universiti to the Royal Commission for t Exhibition of 1851 on forms of applicati for the Commissioners' Science Resear Scholarship to be obtained from t registrars or administrative authorities their universities. 3371(H)

The Second Translation Kit

From the people who brought you new convenience and reproducibility with the first.

The First Translation Kit

It will make your life easier and your results more reproducible

New England Nuclear offers the first reticulocyte lysate kit for use in studying protein synthesis. Not only does it save all of the trouble of preparing your own cell extract, it gives you a system free from endogenous mRNA, high in protein synthesis activity, with an optimized high-activity tracer and quality control that includes testing every lot of Methionine, L-[35S] using the kit.

The rabbit reticulocyte lysate system is reported to contain all factors required for translation of any eukaryotic mRNA! But its use assumes the availability of suitable animals, preparation of the lysate extract, and inactivation of endogenous mRNA. And the meticulous tailoring of the salts, energizer, and amino acid mix. In short, it's a nuisance.

With our exclusive kit you bypass all that and concentrate on the study of protein synthesis. The kit contains:

A rabbit reticulocyte lysate—Treated with nuclease to inactivate endogenous mRNA, and tested to guarantee high protein synthesis activity.

The first tracer available—NEG-009T, NEN's translation grade [35S]-Methionine, >500Ci/mmol, tested for incorporation into protein in cell-free translation systems. Each lot is optimized for compatibility with the system.

Translation cocktail—All the necessary components for proper translation conditions: 19 amino acids (excepting methionine) plus buffer, reducing agent, and energizer.

Control mRNA—Purified exogenous mRNA (adenovirus-infected HeLa cell mRNA) to check the biological activity of the system.

Salts and sterile deionized water—Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

And you can get rid of all those rabbits

The protocol is straightforward, and it includes suggested final assay procedures. So that's our message. Now add yours.

Call us toll free for details.

New England Nuclear

First, Methionine...

Our first translation kit saved you the difficulty of preparing your own lysate for cell-free translation studies, gave you a system free of endogenous mRNA and high in protein synthesis activity, and assured you of components tested for compatibility and reproducible results. All told, it was an excellent excuse to stop cultivating rabbits.

Our second kit does all of the above, too. But, instead of Methionine, L-[^{35}S], the tracer is Leucine, L-[3,4,5-^{3}H]—specially optimized for use with this system. Here's what our Leucine Translation Kit contains:

Rabbit reticulocyte lysate Treated with micrococcal nuclease to inactivate endogenous mRNA and tested to guarantee high protein synthesis activity.

High activity ^{3}H tracer NET-460T, Leucine, L-[3,4,5-^{3}H], >110Ci/mmol. Special lots are prepared and tested for incorporation into protein using this cell-free translation system.

Translation cocktail All the necessary components for proper translation conditions, including buffer, biogenic polyamine, and energizer.

Control mRNA Purified mRNA to check the biological activity of the system.

Salts and sterile deionized water Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

Caution: Not for use in humans or clinical diagnosis.

Instructions for use The protocol is straightforward and includes suggested assay procedures.

So now there are two, and only two, translation kits. Call us toll-free for details on either or both.

CUT YOUR AD BUDGET LATELY?

Honesty compels us to admit that you're not alone.

Whenever the cost/price squeeze gets really tough, it's a temptation to regard advertising as a cost...and to cut.

Not at every company, however.

In recent years, a significant change has taken place in the thinking of many management men about advertising budgets. No longer are appropriations cut automatically when the pressure is on.

Why?

For a number of reasons. Among them are:

1. *With the growth of the marketing concept,* advertising is no longer looked upon merely as an expense, but as an integral part of the company's marketing mix.

2. *Firms that maintain advertising during recession years do better in sales—and profits—in those and later years.* That was proved conclusively in studies of five separate recessions made by ABP and Meldrum and Fewsmith.

3. *The cost of a salesman's call today makes it imperative to make maximum use of advertising.* The average cost of an industrial sales call soared to a record $96.79 according to the latest report by McGraw-Hill's Research Laboratory of Advertising Performance. Yet studies show that a *completed* advertising sales call—that is, one ad read thoroughly by one buying influence—literally costs only pennies. Why deny yourself such efficiency?

4. *In some cases, there is no way to reach customers except by advertising.* The "Paper Mill Study" shows (1) the number of buying influences in the average plant is far greater than marketers are aware of, (2) the vast majority of these influences are unknown to salesmen, (3) no salesman has the time to contact all influences even if he knows them.

5. *Selling costs are lower in companies that assign advertising a larger role in marketing products.* So advertising is an investment in profit, just like a machine that cuts production costs.

6. *Memories are short.* There is an estimated 30% turnover every year among buyers. It isn't surprising, then, that lack of advertising contact can quickly result in loss of share of market.

7. *Most down periods turn out to be shorter than expected.* The history of every postwar recession is that it didn't last as long as predicted. Why gamble your market position for short-term gain?

8. *Consider lead time.* Very few products sold to business and industry are bought on impulse. The advertising you are doing—or missing—right now will have its effect years from now.

9. *Advertising works cumulatively.* It would be nice to think that every reader reads all of your ad. We know it doesn't work that way. To be most effective, advertising must have continuity.

10. *Did your competitor cancel his budget, too?* If not, you may be taking a big risk.

11. *Will you lose salesmen?* They know that their chance of getting an order is better if they are backed up by advertising. Can you be sure of keeping them when they learn that that support has gone?

12. *You know better.* Survey after survey of executives shows that they expect a *drop* in sales if advertising stops.

But there is need for efficiency...

whenever advertising budgets are being assembled—never more than in these inflationary times. Significantly, a recent survey shows that nearly 40% of the average budget for advertising to business and industry is invested in business publication space and preparation. That's *more than double* the next largest item.

Why? Because specialized business publications remain the most effective and efficient method of reaching target audiences in business, industry and the professions.

And we can prove it.

Sephacryl®

the different medium for gel filtration

- Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.
- Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1(1975) and **264**, v, 11 Nov. (1976).

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

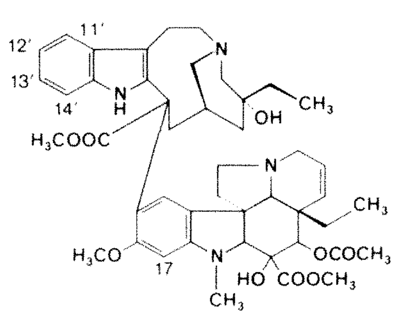
Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:



[G-^{3}H]VINBLASTINE
Code TRK.507
17 .... 44% 11' 8%
12',13' .... 46% 14' 2%

[1ß, 2ß(n)-^{3}H]TESTOSTERONE
Code TRK.162
1∝ .... 5.9% 2∝ 8.2%
1ß .... 46.0% 2ß 39.9%

[6-^{3}H]BENZO[a]PYRENE
Code TRK.501
6 .... >95% 1 .... <5%

D-[2-^{3}H]GLUCOSE
Code TRK.361
2(∝) .... 40% 2(ß) 60%

L-[3,4(n)-^{3}H]VALINE
Code TRA/K.533
2 .... 8% 4 .... 64%
3 .... 28%

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

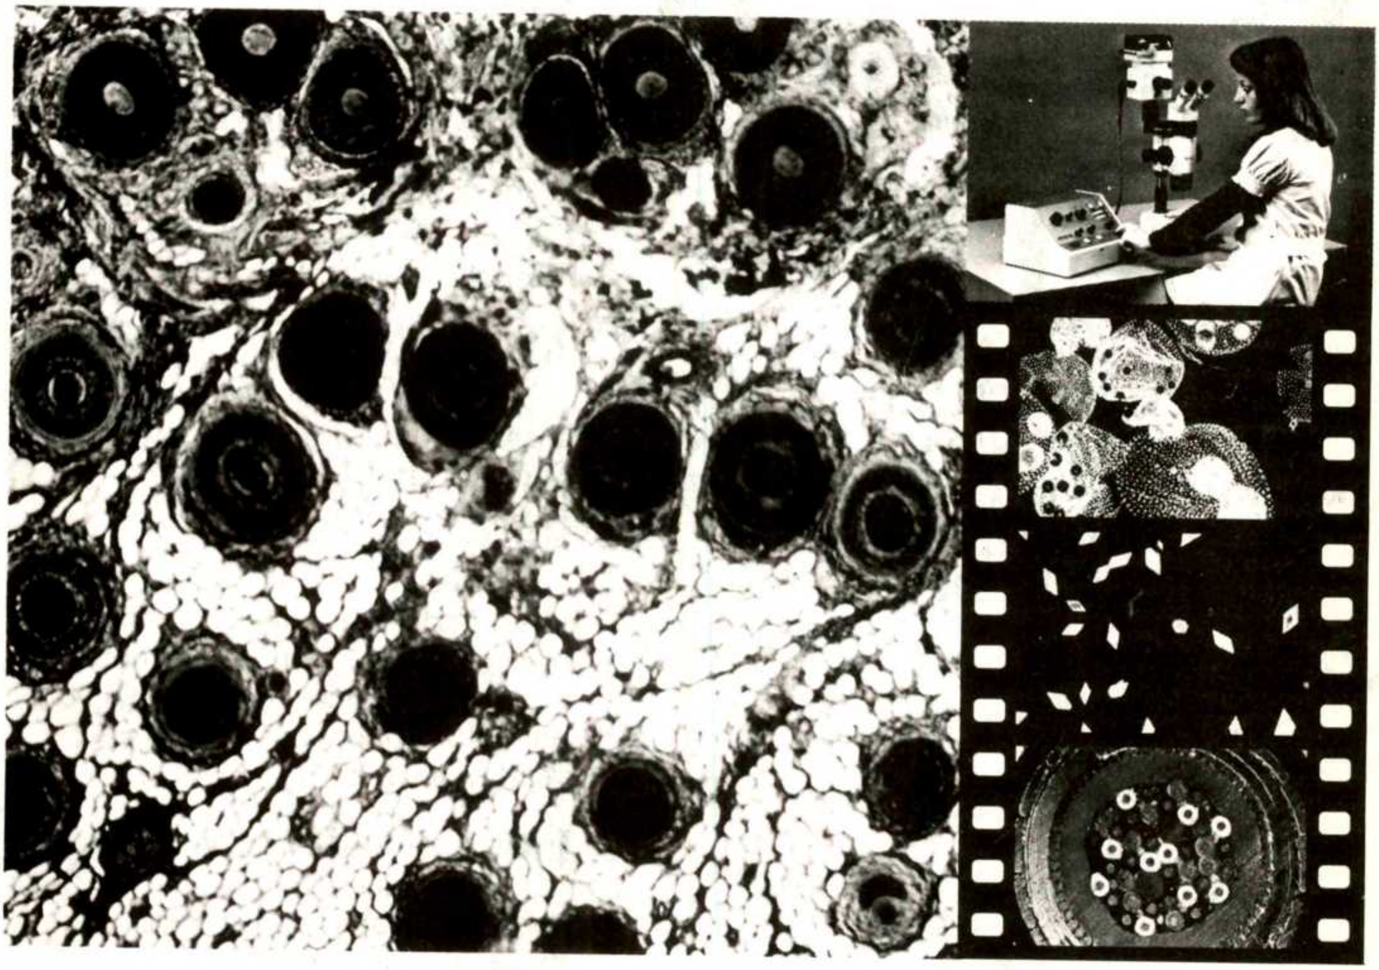
Professional photomicrographs in series.



With the new Wild MPS Microphoto System.

The new Photoautomat from Wild Heerbrugg represents a tremendous stride in the recording of microscopy specimens; an assurance of optimal exposure, superlative imaging and planned work. Everything has been automated: camera factor change between formats from 35 mm to 4 × 5"; super-sensitive exposure measurement for films from 5 to 43 DIN; exposure corresponding to film emulsion, with or without correction for reciprocity failure; film transport. Just concentrate on the specimen and on composing an expressive format. Press the button, and everything is taken care of. This doesn't mean that the Photoautomat jealously guards its secrets! The control unit displays not only the exposure time, but also the percentage of time elapsed, both of which can be influenced individually. That's how photomicrographs are made in series with the Wild MPS. Professional ones.

The various MPS systems for microscopes and stereomicroscopes are described in a colour leaflet. Ask for it.

BP Energy Research Prize

AN INTERNATIONAL AWARDS SCHEME OPEN TO TEAMS AND INDIVIDUALS FROM UNIVERSITIES AND OTHER INSTITUTES OF HIGHER EDUCATION.

As part of its involvement in energy and conservation, BP has established the BP Energy Research Prize.

The aim of the Awards Scheme, is to provide a further stimulus to the development of new ideas concerned with energy conservation and the better utilisation of energy resources.

In the UK, awards to support research programmes and prizes totalling £50,000 will be made available.

The winning project will be the UK entry for the BP International Energy Research Prize.

Judging

Provided by the Royal Society in association with the Fellowship of Engineering.

UK Awards

Three awards, each of £10,000 to support three selected research projects for one year. The winning project will receive a prize of £5,000 plus £10,000 towards a further year's research.

International Prizes

An international competition open to research projects nominated by BP associate companies overseas.

The first prize will be £10,000.

Full details and entry forms obtainable from: BP Energy Research Prize, Britannic House, Moor Lane, London EC2Y 9BU.

Closing date for receipt of completed entry forms is 10th December, 1979.

Cambodia's long path back

Relief operations in Cambodia must be based on accurate information, of which there is little. And a new scientific and medical community will have to be developed.

AT LONG last there seems to be some movement on the diplomatic front over the tortured question of aid to Cambodia. Announcements of a British government provision of more than £4 million in medical and food aid, together with news that Oxfam is starting to take supplies into the country, do at least represent a step forward from the days of wretched international diplomacy in which the precise status of Cambodia's two claimants to power seemed a matter of more concern to the Western countries most capable of helping than did the fact that millions were starving to death. But now in the euphoria that at least something is happening in the short-term, attention must not be diverted from the long-term needs of the area.

Cambodia, or Democratic Kampuchea as it has recently been called, is a very fertile area. The story is told by Prince Sihanouk that US AID officials once visited Cambodian villages to encourage the planting of higher yield varieties and came back the next year not to find bumper harvests but that the villagers were now people of leisure, being able to fulfil all their needs on only half the land. All the more galling then that the successive disruptions of the past ten years — the US bombing, three years of the Pol Pot regime and then the Vietnamese invasion during the planting season in late 1978 — should have brought the country to its present position.

The problem with dispatching aid in the past few months has been the legitimacy issue. Vietnam-supported Heng Samrin has driven the Pol Pot forces into the more inaccessible parts of the country, and by the general rules of diplomacy (as applied for instance to Iran and Uganda) would probably qualify for recognition. But Pol Pot is supported by China, whereas Heng Samrin ultimately receives support from Moscow. And at present China is being courted by so many countries that when the question of recognition of a Cambodian government came up recently, the United Nations voted strongly in favour of seating the Pol Pot regime.

Thus, when the country desperately calls for international assistance there is general confusion. Cool logic suggests that the aid should go by way of Phnom Penh, the capital in the hands of Heng Samrin. But the involves at least some sort of acknowledgement of Heng Samrin's legitimacy — particularly difficult for Britain to swallow since Mrs Thatcher made it clear that she would do nothing to help Vietnam. There are, furthermore, always those who can derail a relief operation by claiming that the assistance will simply fall into the hands of the army, which some of it undoubtedly will.

Mercifully the British government has at last made a substantial step forward, and other countries seem in the process of doing so also. The question then remains of how this avalanche of aid will be put to good use. Observers of the country stress how little is really known of Cambodia's plight. Even the population is a matter of conjecture, estimates varying between 3 and 6 million. Such vital information as the prevalent type of starvation, and the distribution of people — are they in relief camps around the cities, or in scattered villages? — is barely known. And yet the character of relief operations depends crucially on this knowledge. One wonders, parenthetically, whether the United States and Soviet Union, always prepared to launch a satellite to keep an eye on other people's troubles, have an adequate supply of pictures to answer many of the questions concerning population distribution, how they are proposing to make this information available, and if not, why not.

If there are short term problems of the intelligent deployment of aid, there are, equally, long-term problems for the country. To regain its status as the rice bowl of Asia, a vigorous agricultural policy will have to be evolved in the next few months. The last planting, in war-time conditions, only used 10% of the available land — getting back to more normal land usage will not just happen automatically. Nor will medical services revive without much assistance. Estimate of the number of doctors who have survived range between 40 and 50 — a tenth of the figure of a few years ago.

If Cambodia's agricultural and medical community is to be rebuilt properly, a major international operation must be set up very soon to speed the training of qualified manpower. This will need concerted effort by many nations; it is to be hoped that the diplomatic and political considerations which have bogged down relief plans will not prevent institutions in the West from helping in the recovery of a shattered country.

● While governments are beginning to act, there is still enormous scope for charities with their greater flexibility. A UK appeal through the normal channel of the Disasters Emergency Committee has not met with a very generous response. Two charities which do seem to be capable of responding to local needs are Oxfam, Banbury Road, Oxford, and Medical Aid for Cambodia, 36 Wellington Street, London WC2. □

Military in clash over US nuclear fusion research

US physicists claim that the use of heavy ion beams is now a leading contender for commercial fusion technology — but that research efforts are being hampered by the aspirations of the military establishment. **David Dickson** reports

TENSIONS are growing between the Carter administration and the US Congress over the appropriate strategy for pursuing one of the most promising paths towards a commercially-viable nuclear fusion energy programme — namely the use of inertial confinement techniques, which would harness the energy released by fusion during the implosion of a small hydrogen pellet hit by a converging beam of immense power.

The prime cause of this tension is a dispute over whether, since such techniques can be applied to the detonation of nuclear weapons, all research on inertial confinement should be conducted as a military project, or whether the potential civilian applications would be better served through a separate non-classified programme.

Behind this is a more conventional dispute involving competition over access to and control over limited research funds between different national laboratories. Here the current control of inertial confinement research by the two weapons laboratories run by the University of California under contract from the Department of Energy — the Lawrence Livermore Laboratory and the Los Alamos Scientific Laboratory — is being challenged by physicists from some of the major accelerator laboratories. In particular, these include the Argonne National Laboratory in Illinois, the Brookhaven National Laboratory on Long Island, and the Lawrence Berkeley Laboratory in California.

The physicists are particularly concerned that if, as Congress is now demanding, one of the weapons laboratories is designated the lead laboratory for inertial confinement research, this could penalise their own efforts — even though, they claim, these may have the best chance of achieving commercial viability.

Research has been carried out since the early 1960s at the two weapons laboratories on the possible use of laser beams to ignite the hydrogen pellets — a path to fusion which is beginning to compete with more conventional programmes, such as the magnetic confinement techniques being studied at Princeton University.

Work at Lawrence Livermore has concentrated on the use of glass lasers, and has been carried out on a variety of machines of increasing power, the construction of the latest, NOVA, having begun this summer. At Los Alamos, research has been conducted in parallel on the possible use of carbon dioxide gas lasers, and the laboratory is also constructing a large experimental machine known as ANTARES.

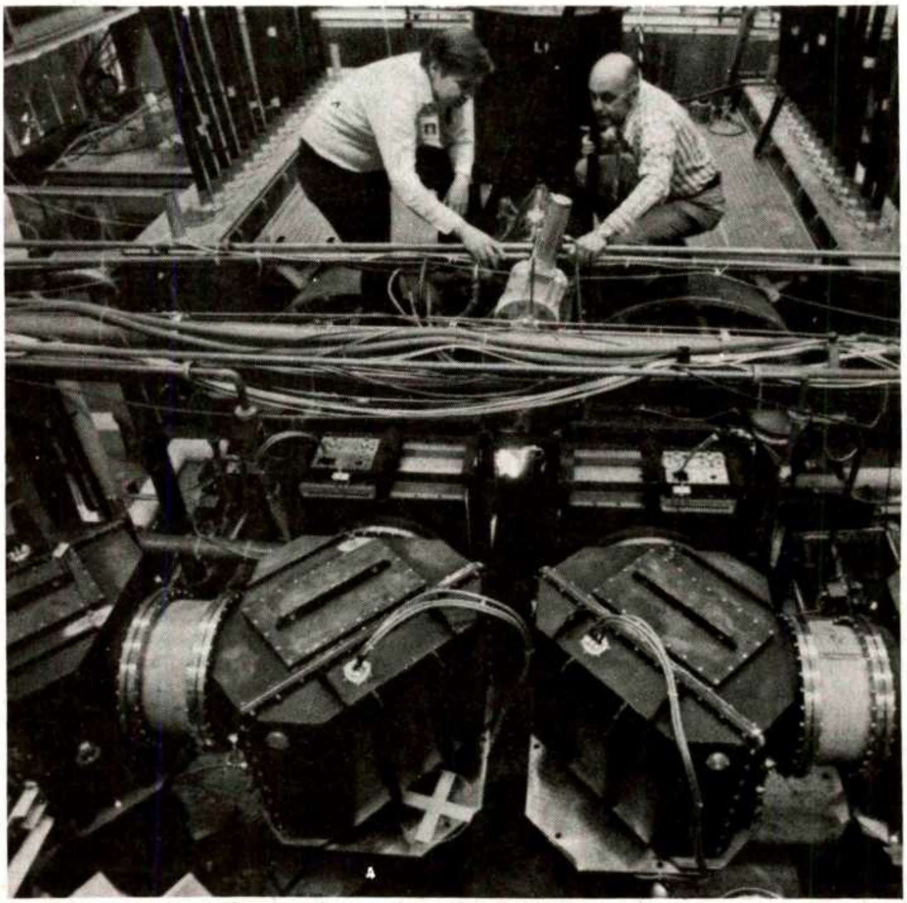
Within the past few years, however, high energy physicists have begun to explore a different approach, using particle beams to provide the necessary 'driving' impact on the pellet. In particular they have considered the use of heavy ions created by the particle accelerators already in use for basic physics research. (See *Nature* **276**, 19-23; 1978).

These physicists claim that two reports — both as yet unpublished — support their contention that there is growing disenchantment with the use of lasers for commercial fusion technology, and that particle beams in general, and heavy ion beams in particular, may offer the most practical solution. But they also claim that since heavy ions have no direct military applictions — there is no way to put an accelerator within a nuclear weapon — their research is not receiving the support it merits.

Strong support for the commercial prospects for heavy ion beam research is said to come from a report prepared for the Department of Energy by Dr John Foster, Vice President for Research at TRW Inc. Although the full report is yet to be published by the DoE, it is said to back-up Dr Foster's statement to the department's Energy Research Advisory Board in May that he considered the use of heavy ion beams to be the "first candidate" for a conservative approach to a workable fusion technology.

The second report has been prepared for the Electric Power Research Institute by a committee chaired by Dr Keith Brueckner, of the University of California, San Diego. Dr Brueckner's report does not make any comparison between the various driver technologies now under study; but it is said to confirm the Foster committee's view that there appear to be no insurmountable obstacles to the use of heavy ion technology. "The current level of funding for heavy ion beam research certainly seems to be incompatible with its promise as a commercial technology," Dr Brueckner said last week.

Both of these reports are now being considered by the Department of Energy as it prepares its budget submissions for fiscal year 1981, which President Carter will submit to Congress next January. And Dr Frank Press, director of the Office of Science and Technology Policy, is said to be among those who have been pushing the department to develop a separate civilian inertial confinement research programme,



Laser research at Los Alamos — but are they off beam?

0028-0836/79/410414-02$01.00

presumably with a greater emphasis on particle beam research.

Such moves, however, are currently being resisted by Congress, and in particular by the House Armed Services Committee, members of which argue that most of the physics of pellet design and energy transmission yet to be understood is common to both military and civilian needs. There would therefore be no need yet to split the two aspects of the research — indeed this could lead to unnecessary duplications of effort.

In passing the DoE's budget request for 1980, the committee therefore directed that the whole of the inertial confinement programme should remain conducted through the weapons laboratories — and added the rider that no money should be provided for specific studies of the commercial applications of inertial confinement fusion, or for "activities which will not be carried out in direct support of the ICF programme leading to military applications."

The committee's feelings were reflected in its reaction to the DoE's budget request. Initially, the department had requested that for 1980, about $3.8 million out of a total budget for inertial confinement research of $146 million should be allocated to heavy ion beam research at the accelerator laboratories.

Following the recommendations of the Foster committee, however, which both pointed out some of the technical limitations facing the expansion of the laser programmes and recommended a major increase in funding for particle beam research, the department suggested some rearrangements in the fusion research budget which would have increased the amount spent on heavy ion beam research to between $12 and $15 million. The suggestion was rejected by the House Armed Services Committee, however, which cut the request back to little higher than its original level.

Keeping options open

Scientists at the two weapons laboratories are still confident that they are justified in concentrating their attention on the physics of glass and gas lasers — even from the point of view of eventual civilian energy production. "It's much too early to make any assessment about the relative merits of the different systems. These are experimental programmes, and progress will only be made through experiments," says Dr Charles Fenstermarcher, programme manager for the advanced driver development at Los Alamos.

"There are many problems in the physics that are not yet understood. And you do not want to drop any option until it is certain that it is not an option."

Most physicists agree with both the DoE and with Congress that it is likely to be several years before a clear idea emerges of the most practical direction for inertial confinement as an energy technology. The problem is that, for each of the possible alternatives, generating the data required to make such an assessment involves considerable capital outlay — and therefore results in competition for relatively scarce funds.

Already Livermore's NOVA, which had originally been scheduled for completion in 1983, and for which Congress had authorised the full construction costs of $195 million, has been cut back following the recommendations of the Foster committee, and is now proceeding in two stages, construction of the first of which started in May.

Physicists at the accelerator laboratories hope to catch up — and possibly to pass — the weapons laboratory researchers in two stages, first by carrying out a joint accelerator technology demonstration programme to show the feasibility of their ideas, and subsequently, if this is successful, to move to a larger-scale machine capable of carrying out target experiments.

The first step in this process would include a substantial commitment to heavy ion beam research in the 1981 budget, possibly in the region of $20 million, with the bulk of the funds going to Argonne and Berkeley, and the remainder distributed between the other laboratories.

The next stage would obviously be more expensive. Designs have already been produced for a heavy-ion demonstration experimental facility (HIDE), which would be capable of reaching energies of 100 kilojoules, but could cost more than $100 million (and theoretically it might make more sense to go directly to an even bigger machine, costing about $500 million).

Shortage of funds could, furthermore, be accompanied by a shortage in qualified research scientists. The House Armed Services Committee points out in its report that "since this is a relatively new technology, the supply of such people is small"; accelerator scientists argue this may be one reason the weapons laboratories are reluctant to see a proliferation of inertial confinement research programmes outside their control.

They also claim that the fact that much of the current research must remain classified is one hindrance resulting from a military-controlled programme — arguing that it should still be possible to deal with the classification of potentially sensitive details even within a programme directed outwards non-military goals (as happened, for example, in the early stages of the nuclear power programme).

But whether the administration will be able to persuade Congress of its claim for the need for a separate civilian inertial confinements programme, in the face of a military establishment which sees such a programme as undercutting its own interests in such research, remains an issue that will be fought out bitterly in the months ahead. □

Congress boosts spending on health research

THE US Congress has agreed to increase the research budget of the National Institutes of Health by 8.2% to a total of $3.4 billion for fiscal year 1980. This is despite President Carter's contention in his budget request at the beginning of the year that since the NIH had received a budget increase of almost 25% in the current year, no further increase was necessary.

In discussing their separate versions of the Department of Health, Education and Welfare's Appropriations Bill, representatives in both the Senate and the House agreed to a total NIH budget which includes recommended increases that had previously been made by both sides. In particular, this will mean that for the first time the budget of the National Cancer Institute will exceed one billion dollars next year. It will also mean an increase of $26 million, as suggested by the House, for the National Institute of Arthritis, Metabolism and Digestive Diseases.

Representative Boland: dispute over Galileo

In a separate action, Senate and House conferees agreed on a budget for the National Science Foundation of $996 million dollars for 1981. Although less than the President's request for $1,006 million, this still represents an increase of 9.3% over the current year's budget.

The conferees also agreed on a budget increase of 8.2% for the National Aeronautics and Space Administration, including a 9.9% increase as requested by the Administration for research and development. Final action on NASA's budget, however, has been held up by a row between the two legislative bodies over future funding for Project Galileo, a proposed two-spacecraft mission to Jupiter.

The House, at the recommendation of representative Edward Boland, wants its appropriations committee to have the power to veto any proposals to split the mission — which may be necessary as a result of delays to the Space Shuttle. The Senate has refused to accept the condition and NASA's 1980 budget has been held up. □

Uranium strip mining: "like going to the Moon"

Unhappy hunting grounds: the Indian end of nuclear energy

Joe Schwartz talks to Winona LaDuke and Herb Blatchford of the American Indian Environmental Council about the hazards of uranium mines in native lands

"THEY start by taking core drills. Then the rigs move in, next to a house or a corral, it doesn't matter to the companies. The pumps spray radon saturated water out on the ground where it forms radioactive pools. Animals drink it. Children play in it. The dogs become listless. The children sleep all night without resting. They complain of nausea. Dietary problems and gastro-intestinal complaints are common."

Herb Blatchford, 51, and Winona LaDuke, 20, of the American Indian Environmental Council (AIEC) were in London last week for a short stopover on their way to the Copenhagen Conference on Uranium Mining and Indigenous Cultures on 18-20 October. "It's an international conference of irradiated natives" says Winona LaDuke drily. But, with most of the world's uranium mining taking place on the lands of native people, Blatchford and LaDuke have a lot of first hand experience about what goes on at the "front end" of the nuclear fuel cycle. SCRAM, the Scottish coalition of environmental groups, had invited them to Edinburgh to discuss the planned uranium mine in the Orkneys that will fuel the Torness power plant (20 September, page 171).

"The disruption is unbelieveable" says Blatchford. "In fact it's so bad that Nixon's Project Independence in 1973 called for 'National Sacrifice Areas.' The Dineh (Navajo) lands in the New Mexico and Arizona were to form the southern end of an energy corridor extending up through Wyoming, South Dakota and into Saskatchewan that would end up a total wasteland.

"The largest uranium strip mine in the world is located at Laguna Pueblo near Albuquerque. It's owned by Anaconda. Going there is like going to the moon. People are listless, the animals show no motion, there are machines grinding all the time. The mine covers the whole valley and the Rio Paguate is a fluorescent green. Originally it was farming community."

Energy development in the American Southwest is intense. Navajo lands at present house four coal mines, five coal fired power plants, 36 operating uranium mines, six operating uranium mills and six abandoned uranium mills. Winona LaDuke describes how these arrangements are negotiated. "The leases are negotiated through the Bureau of Indian Affairs in consultation with tribal councils. The tribal councils are a creation of the BIA, the usual form of native government being a council of elders with decisions taken by consensus. The tribal councils are funded by the BIA. In the Navajo lands there are 74 members of council earning $13,000 a year. The average Navajo income is $1,400 a year.

"Royalties are minimal. The present rate of $0.6 a pound for yellowcake is a royalty of 1.2% of the market price of $50 per pound. You have to compare this to the standard royalty of 12% paid to the Bureau of Land Management and the Federal Parks for resouces taken out of other federal land. The royalty is paid to the Area Director of the BIA and is given out only with the approval of the Secretary of the Interior. We are legally wards of the government not beneficiaries so we have to beg back the money that is supposed to be ours."

Court cases to change the legal status of the Indian nations or to alter present contracts have failed. Last spring the Jicarilla (Apache) in Northern New Mexico managed to win a tax case meaning that they will no longer have to pay federal tax on their royalties. LaDuke says this is unique to native communities in the world. "There's nothing compared to it. It's a system of involuntary servitude. For example, in one year the Dineh (Navajo) nation exports enough energy to provide the needs of the state of New Mexico for 32 years. But 85% of Navajo households don't have electricity. This makes the Navajo nation an energy colony."

But finally, it is the hazards of uranium mining itself that is the urgent issue. "Eighty five per cent of the released radioactivity remains in the tailings. Rainfall tends to release the Rn222 which in New Mexico rises to the Continental Divide and then settles back down collecting in basins. We are starting to see long range effects now."

After a major exposé in the *Washington Post* last year, the US Public Health Service attempted to locate some 250 Navajo and 400 white miners who had worked the Red Rock Cove mine near Shiprock operated by Kerr-McGee. Of 100 miners eventually surveyed, 25 had died while still in their 40s and an additional 20 were found to have cancer.

The environmental prognosis for non-miners appears to be poor. A Los Alamos report (*Uranium Mill Tailings, Environmental Implications,* February, 1978) was pessimistic about the possibilities of controlling radon release. "Our research indicates that 12 feet of clay are required to reduce the radon exhalation rate by 99% and the remaining 1% is still about four times the typical soil exhalation rate.

"Perhaps the solution to the radon problem is to zone the land into uranium mining and milling districts so as to forbid human habitation."

In spite of the demonstrable hazards and what Herb Blatchford calls the "ultraexploitation" of native peoples there is going to be opposition to change. The AIEC called a demonstration at Mt Taylor to protest at a Gulf Oil uranium mine and mill complex which plans to produce 100 million pounds of uranium. On the same day the Energy Association of Taxpayers, an organisation funded by the energy companies, sponsored an Energy Fair in nearby Grants, the self proclaimed "Energy Capital of the World." Following

0028-0836/79/410416-02$01.00

a parade with floats carrying the slogans "Who Sabatoged Three Mile Island?" and "Uranium for Our Children", New Mexico Senator Harrison Schmidt told the rally:

"I will do everything in my legislative power to eliminate the need for environmental impact statements for future uranium mines and mills." □

And in the meantime, in the UK, the Central Electricity Generating Board made a £150 million bid for a share in the Ranger uranium project on native lands in Northern Territory in Australia. According to the *Guardian*, the CEGB bid is to safeguard Britain's growing need for uranium which is expected to incrase by 2½ times in the next 10 years. □

Spanish scientists protest over looming cash crisis

Fifteen Spanish scientists last month published an open letter to their government. They claimed that research would be brought to a halt in 1980 if the government did not act quickly to provide funds. The letter, which appears below, was communicated to us by a Barcelona scientist, Dr Juan Subirana, whose further comments appear this week in correspondence (p 424). The scientists' difficulties appear against an annual inflation rate of 25%, an extensive attempt to curb government expenditure, and a near-complete lack of scientific representation in parliament

“State-financed research groups in Spain are in great difficulties for lack money — and if the government fails to take immediate action, their problems will be dramatically worse next year. On 31 December this year financial support for all projects approved by the Comision Asesora de Investigacion Cientifica y Tecnica will end. The projects were announced in 1975 and 1976.

As you know, scientific and technical research in this country has three financial sources:

- Institutional finance through the universities, the council for scientific research (CSIC), and the research centres of ministries of agriculture, industry, health, public works, transport, and communications;
- Grants from Spanish or foreign foundations and those derived from bilaterial international agreements; and
- The Comision Asesora de Investigacion Cientifica y Tecnica (CAICT).

The first of these sources, instutitional finance, covers little more than maintenance, particularly in the case of the universities and the CSIC. Research funds come mostly from foundation and international grants and the CAICT. In the universities and the research centres of the CSIC at least 80% of the funds available for research come from the CAICT. Yet up to this date there has been no invitation from the Comision for proposals for new projects beyond the end of this year.

Since there are no substantial alternative sources, research — at least in the universities and the CSIC — will virtually cease on 1 January 1980.

The consequences are obvious: projects underway will have to be abandoned, in many cases with the loss of everything already achieved; and scientists in training and contracted auxiliary personnel will have to leave their laboratories.

The Comision Asesora was established in 1958. Recently it has come to belong to the Ministry of Universities and Research, with its annual budget of 1.1 billion pesetas ($17 million) dedicated to research. We understand that the Comision is being reorganised, but we do not understand why this reorganisation has halted the existing mechanisms for distributing Comision funds. We also understand that the government has prepared a three-year plan for research support which will be discussed in parliament, but it seems clear that no funds will be forthcoming from that plan until the second half of next year.

For the survival of science, we ask the government, through the Ministry of Universities and Research, to take urgent measures. We scientists signing below believe we speak as representatives of many others when we propose that the government should:

- Immediately announce the offer of Comision Asesora research grants for 1980, and assure that the selection procedure is complete by the end of the year
- As a matter or urgency, put the three-year plan for research before parliament.

So our country may have a minimum of independence and intellectual respect, political changes must go along with deep changes in our scientific and technological policy; but these changes must not be made at the expense of a temporary paralysation of Spanish research.”

Signed: Manuel Ballester, CSIC Barcelona, Nicolas Cabrera, Universidad Autonoma Madrid, Antonio Cordoba, Universidad Complutense, Jose Maria Fontbote, Universidad de Barcelona, Alberto Galindo, Universidad Complutense Madrid, Antonio Garcia Bellido, CSIC Madrid, Antonio Garcia Olmendia, Universidad Politecnica Madrid, Antonio Gonzalez Gonzalez, Universidad de la Laguna, Jose Antonio Jimenez Salas, Universidad Politecnica Madrid, Jose Maria Jover, Universidad Complutense Madrid, Ramon Margalef, Universidad de Barcelona, Francisco Rodriguez Adrados, Universidad Complutense Madrid, Jose Maria Serratosa, CSIC Madrid, Alberto Sols, Universidad Autonoma Madrid, Agustin Udias, Universidad Complutense Madrid.

The day after this letter appeared in the Spanish press, a meeting of the joint council of the CSIC, the universities, and the Ministry of Universities and Research took place. The meeting had already been planned as part of the efforts to create a research policy for Spain. The press commented on 28 September:

El Pais (Madrid)

"The Ministry of Universities and Research is studying the reorganisation of the CSIC as one of the first steps in the redefinition of research supported by the administration. Among other measures there are the preparation of a general report on research in Spain, the three-year (1980-82) plan of research, cooperation with other administrative bodies, etc. In particular the remodelling of the Comision Asesora de Investigacion Cientifica y Tecnica is also being considered.

King Juan Carlos: trouble with science

"Publication appears imminent in the *Boletin Oficial del Estado* (the official government journal) of a decree that will approve the new bye-laws of the Comision, which is the advisory board of the government in scientific policy, and which has as a main mission the approval of research projects under government support and the distribution of funds to finance them."

La Vanguardia (Barcelona)

"[The Comision Asesora has decided] not publicise now an annual announcement of projects, as requested by a group of scientists in a recent open letter to the Ministry of Universities and Research. The reason is that the 250 million pesetas ($4 million) available to the Comision would not solve the scientists' economic problems, while it seems more convenient to transfer this quantity to the next year and not to proceed with the announcement before January 1980".

It thus appears that the situation of science in Spain is far from clear, and is continuing to give scientists considerable anxiety. □

West Germany: a nuclear incident every three days

OVER the past two years, one incident or accident has occurred on average every three days in West German nuclear power stations, according to a recent report of the Bundesverband Bürgerinitiativen Umweltschutz e.v. (BBU), the chief organisation of German environment protection groups and associations. The report, "Accidents in German Nuclear Power Stations. Publication of Confidential Incident Reports of the Federal Government", also claims that most of these incidents have been kept secret. Information for the report was obtained from the files of the Gesellschaft für Reaktorsicherheit (GRS), the German Reactor Safety Society.

Publication of the BBU report came shortly after the German Minister for Research and Technology, Volker Hauff, released part A of the report of a risk study of nuclear power stations in West Germany — the German version of the Rasmussen Report. The study concluded that the probability of an accident is extremely low. Ironically, the author of the study is the GRS, the very same society from which the BBU obtained its information.

GRS is a limited liability company based in Cologne with the Federal government, Bavaria, Northrhine-Westphalia, some technical supervisory bodies and the German Lloyd (an insurance company) as shareholders. In 1974/75, the Federal Ministry of the Interior commissioned the GRS to collect and categorise all data relevant to incidents and accidents in German nuclear power stations (and also, as far as possible, in foreign ones). The aim was to improve safety by mutual exchange of information between utilities and concerned authorities.

In fulfilling this commission, the GRS obtains short standardised reports from the utilities which have been prepared whenever deviations from routine operations have occurred. The deviations or incidents (*besondere Vorkommnisse*) are divided into three categories according to their significance for the safety of the plant and the public:

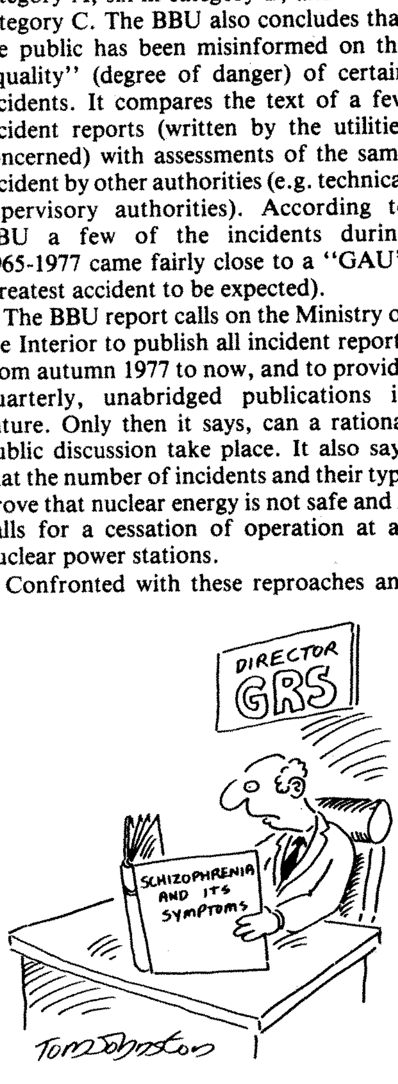
- Category A includes incidents that immediately threaten safety, for example: emission of more than the maximum permissible amount of radioactivity; breakdown within the primary circuit combined with emission of radioactivity or with coolant leakage.
- Category B includes incidents that are a potential threat to safety, for example: unplanned emission of radioactivity below permitted amounts; breakdown of system components with importance for safety during tests (if not during normal operations).
- Category C includes any other kind of deviation from specified norms and safety regulations.

The utilities themselves categorise individual incidents so that the GRS simply list the collected data and sends both the incident lists and the individual incident reports four times a year to the Ministry of the Interior, and its other shareholders.

It was these lists and reports from 1965 to autumn 1977, that the BBU has published together with a few comments, interpretations and supplements from other sources. Its report is not easy for the uninitiated to understand, because no systematic interpretation has been done, incidents of differing relevance being catalogued only by time and location. But it is a unique source of information in West Germany. In the introduction, the BBU compares the official risk study report with the confidential lists and incident reports. It concludes that the public has been misinformed on the number of incidents which have occurred. For example in 1976 according to GRS data 139 incidents, 24 in category A, 85 in category B, and 30 in category C occurred. A Federal Government document, however, called "On the peaceful use of nuclear energy" mentions only 14 incidents in 1976, six in category A, six in category B, and two in category C. The BBU also concludes that the public has been misinformed on the "quality" (degree of danger) of certain incidents. It compares the text of a few incident reports (written by the utilities concerned) with assessments of the same incident by other authorities (e.g. technical supervisory authorities). According to BBU a few of the incidents during 1965-1977 came fairly close to a "GAU" (greatest accident to be expected).

The BBU report calls on the Ministry of the Interior to publish all incident reports from autumn 1977 to now, and to provide quarterly, unabridged publications in future. Only then it says, can a rational public discussion take place. It also says that the number of incidents and their type prove that nuclear energy is not safe and it calls for a cessation of operation at all nuclear power stations.

Confronted with these reproaches and demands, the Federal Ministry of the Interior reacted almost too calmly. It said that the Bund and Länder have been informing the public of all relevant incidents in German nuclear power stations since 1966 and that Parliament is continually informed of all incidents (not only those with safety relevance). Public information is given only on incidents that threaten the safety of a power station and/or the public according to "expert assessment". The 14 incidents, mentioned in the Federal Government's documentation for 1976 are according to the ministry, "representative" and not the total number of incidents.



According to competent experts within the Federal Ministry of the Interior, there is confusion over nuclear information in the FRG revealing a lack of competence and a lack of political awareness that the public must be totally and regularly informed. There is the unique situation in the FRG, that the utilities possess a kind of "copyright" over incidents. This stems from the "Gewerbeordnung" (trade and manufacturing ordinance) a law made for small manufacturers and the "Atomgesetz" (law on nuclear energy). Both are influenced by the same ideas on 'rights of possession'. There is, therefore, no absolute compulsion on the Bund or Länder to publish information on incidents, except where it serves to improve safety conditions (as stated in the "Atomgesetz").

The prime responsibility for nuclear incidents, however, rests with the Länder. The Federal Government, represented by the Ministry of the Interior has only certain supervisory rights over the relevant Länder ministries although it has to inform the Bundestag. Now the Länder provide information on each incident. This used to be done by the Federal Ministry of the Interior before 1976/77, when a first list of incidents (compiled originally for the competent committee of the Bundestag) was published in the ministry's journal *Umwelt* (environment). The list, however, was not complete and the individual incident reports were not published — possibly because of the utilities' "copyrights". As was explicitly said, the list was only "representative".

There now exists an extension to the list for 1977 and 1978. It went to the competent committee of the Bundestag at the end of May 1979 and will be published in *Umwelt* on 12 October. Is this chance or a consequence of the BBU publication? A spokesman for the ministry claimed that "publication was planned long ago, it had to be prepared before the summer recess". The ministry now says that there are no intentions of publishing quarterly or regular lists of incidents or of publishing the individual incident reports made by the utilities. **Klaus Höpfner**

Germany to decentralise nuclear waste treatment

GERMANY'S ambitious plans to build a huge nuclear waste disposal centre at Gorleben in Lower Saxony have finally been dropped, despite pressure from the federal government. On 30 September Chancellor Helmut Schmidt and the Minister-President of the eleven German Länder agreed to abandon the plan after a series of lengthy negotiations. And the nuclear industry have now decided to approach the problem in smaller stages.

After an international six-day hearing last May (24 May, page 283), Minister-President Ernst Albrecht of Lower Saxony (CDU) had rejected plans to build an integrated nuclear waste disposal centre at Gorleben. However the Federal Government under Chancellor Schmidt (SPD) continued to adhere to the concept of an integrated waste disposal centre. The result was stalemate and additional delays to nuclear expansion in West Germany — because of the law-courts' insistence on feasible nuclear waste management before granting licences to new nuclear power plants.

But now Chancellor Schmidt and the Minister-Presidents of the Lander have agreed on the following points:

- West Germany is to manage the whole of its nuclear fuel cycle but in small units at different sites.
- No reprocessing plant of any kind is to be built at Gorleben in the foreseeable future. Instead, the possibility of building one or more small reprocessing plants at other sites in West Germany is to be investigated and the final decision on reprocessing is to be taken by the mid 1980s.
- Testing of Gorleben saltdomes for final storage will continue.
- Lower Saxony and Northrhine-Westphalia have agreed to build two or three intermediate storage facilities which will be needed for about 20 years before a final solution to the storage problem is developed. The Bavarian criticism that "compact storage facilities" within nuclear power stations "contribute to the intermediate storage problem" has been taken into account.
- Research into alternatives to reprocessing, in particular final storage of unreprocessed spent fuel, is to be supported.

But there many unknowns in this political solution. One certainty, however, is that no reprocessing plant will ever be built at Gorleben — Minister-President Ernst Albrecht is trying to avoid endangering his political career, especially as he is a potential candidate for the chancellorship in 1984 or 1988. A complete new reprocessing plant may never be built especially if ideas to enlarge the existing experimental plant at the nuclear research centre in Karlsruhe are adopted.

However the problems of siting intermediate storage facilities might be only marginally easier than those of siting reprocessing plants and final storage facilities. In Ahaus (Northrhine-Westphalia), for example, which has already been selected as the site for intermediate storage ponds, the CDU lost 20% of their former votes during local elections last week while a recently-formed opposition group won 25% of the votes.

Further, the question of whether the law-courts will accept the intermediate storage compromise as a solution to the waste management problem for the time being is still open. And last but not least, the congress of the governing SPD (Social Democratic Party) will be held in Berlin in December. Nuclear power will top the agenda.

Klaus Hopfner

Soviet psychiatrist attacks 'Snezhnevskiism'

MOSCOW'S psychiatric establishment has now produced its own internal dissent — according to US psychiatrist Walter Reich. He was referring to an article, soberly titled "Differentiating Exogenous Psychiatric Illness from Schizophrenia", which was apparently sent abroad by unofficial channels and appeared in the August issue of the US "Archives of General Psychiatry".

Of itself, the article appears to be simply a criticism of current Soviet diagnostic procedures. On the basis of an analysis of more than 300 patients, the author, Dr Etelii Filipovich Kazanets of Moscow's Servskii Institute of Forensic Psychiatry speaks of many "over-diagnoses", "incorrect diagnoses", the necessity for "revising many long-standing diagnoses" and the "criteria, associated with the Snezhnevskii school" which "over-extend the diagnosis of schizophrenia".

For Andrei Snezhnevskii, head of the Institute of Phychiatry of the Soviet Academy of Medical Sciences, all mental illness is some form of schizophrenia. Indeed, he has identified a number of types which seem of specifically Soviet provenance, including "sluggish" schizophrenia which, it appears, has no presenting symptoms except political dissent.

Dr Kazanets, it must be stressed, does not in any way refer to the "political" application of Snezhnevskii's theory — although coming from the Serbskii Institute which has been responsible for many diagnostic reports on dissidents. Indeed, he does not even say that the patients whom he reviewed were in fact in good mental health — only that they were suffering from brief "exogenous psychoses" which could have been cleared up in a short time, without for the long "rehabilitation" process with compulsory attendance at psychiatric outpatient clinics and domicilary visits.

Where, then, lies the "daring" which Dr Reich — known as a moderate and cautious commentator — finds in the article? It should be stressed, perhaps, that even apart from its provenance, the study is, in the words of Jack Weinberg, former president of the American Psychiatric Association, scientifically "significant".

Of recent years Snezhnevskii's theory of schizophrenia has made a number of western psychiatrists wonder how long a meaningful dialogue with their Soviet opposite numbers would be possible. Irrespective of the political misuse to which they could be put, Snezhnevskii's views, it was felt, could impose a Lysenko-type isolation on Soviet psychiatry.

To attack these entrenched ideas, Dr Kazanets was obliged to send his manuscript abroad "privately", bypassing the official postal (and censorship) channels — an action which in itself could have serious consequences. Yet the article is, in itself, controlled in tone. Certainly, as western commentators have been keen to point out, he notes that the "prolonged retention of individuals on psychiatric, dispensary lists long after their recovery infringes on rights" (*not* "human rights" as it has been misquoted). He also implies, however, that Soviet society as a whole may suffer: the "illegal inclusion of persons not mentally ill on psychiatric rosters" may entail "criminal elements" being unjustifiably freed from "responsibility for their crimes".

Dr Kazanets has long been considered something of a "loner" and "troublemaker" by his colleagues, and it is not surprising that he should be the first to raise his voice in qualified criticism of Snezhnevskii. Nor is it entirely surprising, that some cracks are occuring in the monolith of Snezhnevskiism. Already some "establishment" psychiatrists are known to have associated themselves with the dissident "Working Commission for Monitoring the Use of Psychiatry for Political Purposes" (a body which in spite of official harassments is still producing a regular bimonthly *samizdat* bulletin).

One should not, however, be over-optimistic. So far there is little indication that Dr Kazanets has any great following, although at least one of his colleagues has been prepared, privately, to testify to his intelligence and "stimulating" personality. Such an assessment may well be needed in months to come — for already there are hints that certain Soviet "establishment" psychiatrists are referring to Dr Kazanets's challenge as itself as symptom of — "schizophrenia".

news in brief

US Senate agrees to circumvent environmental legislation: The US Senate agreed last week to support President Carter's proposals to establish an Energy Mobilisation Board to cut red tape on selected large energy projects. This was despite the objections of environmentalists and state and local groups that the board's powers to speed up the review process could undermine many of the environmental laws that have been passed in recent years, and would trample on the rights of local governments. An intense lobbying effort by Carter and by the oil industry managed to secure the defeat of an amendment from Senator Abraham Ribicoff and Senator Edmund Muskie that would have eliminated these provisions from the Bill setting up the board. The measure now passes to the House of Representatives, which is already considering two versions of the Bill, one of which — passed by the House Commerce Committee three weeks ago — would give the board even stronger powers to ignore what it considered to be unreasonable environmental legislation. Meanwhile, a report prepared by a Senate budget committee and issued last week stated that the President's proposal to reduce oil imports through massive development of synthetic fuel production cannot presently be justified on economic grounds.

Fuelling guided missiles can seriously damage your health, as well as causing a major threat to the environment, according to Chinese military experts. Charging a missile with liquid fuel is a delicate task, involving an accurate determination of the temperature in the fuelling trough. Conventional sampling methods entail drawing off a sample of up to 40 kg. This deteriorates in contact with the air during the measuring process, and is afterwards voided, seeping into the soil and polluting the ground-waters. There is also considerable atmospheric pollution and health hazard, apparently from reaction fumes. To overcome these disadvantages (and to save the state the 1500 yuan spent annually on the wasted fuel), two members of the "fuelling squadron" — platoon leader Wang Enchen and technician Xun Chengzhi — have developed a closed-loop test method which gives a direct readout from a temperature gauge permanently fixed inside the test chamber. In a recent broadcast, Peking radio stressed the prolonged research in metallurgy and the science of refractories needed before on effective system was perfected. But now, said the commentator, this sophisticated system has saved state research and development funds, improved working conditions for the fuelling personnel, and shortened the average fuelling time from ten hours to six (and on one occasion, only 2.5).

US experiments carried by Soviet satellite: An international collaboration on the effects of weightlessness on animal and bacterial growth was launched 26 September in the Soviet Union. The major payload consists of 38 white rats and 60 fertilised Japanese quail eggs shared among experimenters from the participating countries which include the US, France and Czechoslovakia. The launch is similar to two previous Cosmos missions in 1975 and 1977 in which the US also participated. In addition to experiments on embryonic growth in both mammals and birds, studies will be made of changes in animal muscle and bone in an attempt to investigate the reasons for calcium loss in the bones and loss of muscle strength by astronauts and cosmonauts during prolonged space flights. The flight will last three weeks.

West German government outlines biotechnology programme: In response to a formal parliamentary question, the Federal Ministry for Research and Technology (BMFT) has published its appraisal of West Germany's present position in biotechnology. West Germany is in the middle rank for biotechnological research, well behind the US and Japan but with a research effort comparable to the UK and France, says the BMFT. In certain sectors, West Germany has reached international standards — for example in the production of single cell proteins from methanol, in cell culture technology, in basic research for bioreactor development, and in the production of compounds by enzymatic conversion.

For the first time the 1980 research budget contains a separate entry for research and development in biotechnology, amounting to 37 million DM. The government's aim is to improve the current standard of research and to facilitate industrial implementation of research results. The government also wants to reach international standards in the following areas: design and construction of bioreactor systems in sewage treatment; biosynthetic processes; fixation of bio catalysts; gene technology and plasmid research; biological nitrogen fixation; and bioenergetics and renewable raw materials.

French government backs down on faulty nuclear start up: A five-day strike by the socialist and communist trade union federations, the CFDT and CGT, has forced the French government to postpone the loading of its Gravelines 1 and Tricastin 1 nuclear reactors. The French electricity authority will convene health and safety committees to investigate the implication of the fissures in the tubular plates of the heat exchanger (*Nature* 27 September) and will make further checks, not expected to take more than three weeks, on the faulty parts. The existence of the cracks up to 6 millimetres deep was made public on 22 September but the government announced its plans to go ahead with the fuelling on 3 October. Although up to 20 reactors are affected, the government argued that the cracks would have to be 60 millimetres deep to constitute a serious hazard. The government's decision provoked a storm of criticism throughout France as political and environmental groups joined the trade unions in protesting the government's decision. Eighteen organisations issued a joint statement on 3 October calling on the government to "refuse this fantastic industrial gamble which could have very heavy consequences." The faults in the heat exchanger plates raise the question whether the plates could actually break. Collapse of the plates means instant and uncontrollable release of water from the primary cooling circuit which would result in a complete loss of coolant.

WHO report criticises current European occupational health programmes: The World Health Organisation has released a stinging critique of routine health examinations for workers exposed to occupational hazards. The report says that European countries have placed too much emphasis on medical examinations and not enough on elimination of industrial hazards. "The fact is sometimes overlooked that the examination of a worker does nothing to eliminate the hazard . . . . Technical improvements should be considered first and the goal should be to make examinations unnecessary by eliminating hazards in industries." The study, a survey of industrial health practices in Finland, the German Democratic Republic, Poland, the USSR and the UK, questions the efficacy of periodic health examinations which are undertaken on a "considerable" scale by European governments. Criticising the lack of knowledge of physicians of the physical and mental requirements of specific jobs, the difficulty of predicting the consequences to health of exposure to industrial hazards and false negative results of many clinical and laboratory tests, the report claims that present practices are wasteful and avoid the real problem of prevention. "If the cost and benefits of the examinations are compared with the really effective alternative, the elimination of the hazards, the present practice in many countries will be shown to be uneconomic."

● The second author of last week's article on geological aspects of nuclear waste disposal (4 October, 332-4) should have been D.A. Gray, not D.A. Greenwood.

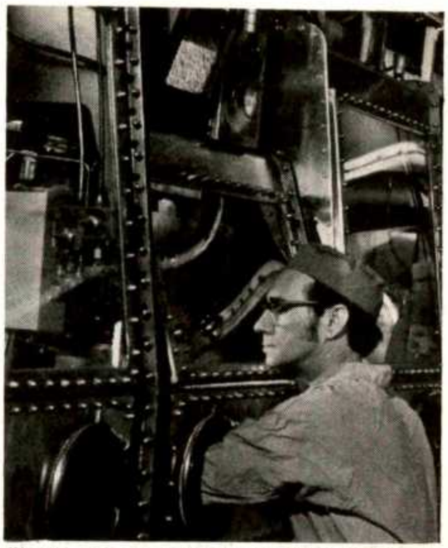
Containing Recombinant DNA: how to reduce the risk of escape

David R Lincoln, Laurence R Landis and **H Andrew Gray** describe a 'fault tree' analysis of containment facilities which, when applied to Fort Detrick (right), enabled them to suggest how to cut the chance of an escape from one in 15 years to one in 22. The authors are from Carnegie-Mellon University, Pittsburgh



The technique of recombining DNA from a foreign source into a host organism could have harmful consequences only after a sequences of events, if at all. An organism must escape from the containment facility, there must be another living system present, the living system must become infected, and the recombinant DNA (RDNA) organisms must bear some harmful action which is released to the living system. (This very generalised framework does not account specifically for differences in the action of toxic compounds, immune responses, or other possible responses.)

Several biological studies have been performed during the last six years which have influenced the understanding of the probability of infecting a living system, and of the infection having harmful effects.[1-5] However, limited research[6-8] has been performed to increase the knowledge of the adequacy of capabilities of the different physical containment facilities for RDNA experiments, or for experiments with known pathogenic organisms and viruses. We describe a framework for assessing the containment system reliability with fault tree analysis.

Engineers use fault tree analysis to indentify the various combinations and sequences of component failures which lead to an undesirable event in a system — such as the melt down of a nuclear reactor. The technique is particularly suited to the analysis of complex systems because it can effectively model a vast number of system components.

The procedure is performed stepwise, with the first decision being a choice of the 'top' event, which is an undesirable event associated with the system. The next step is to determine all the necessary conditions, or secondary events, which will cause this top event. If two secondary events must both occur to cause the top event, these two events will be linked in the tree to the top event by an 'and' gate. However, if either of the events will cause the top event, the secondary events will be linked to the top event by an 'or' gate. An ordering of causative events will be generated through subsequent steps, until finally a set of primal events is reached. These are events whose causes need not or cannot be determined.

'Cut sets', which are independent paths or sets of primal events which cause the top event, are then determined. Any cut set having no subsets indentical to any other cut set is defined as a 'minimal' cut set. The frequencies and probabilities of the minimal cut sets are calculated, and the frequency of the top event is the sum of the frequencies of all the minimal cut sets. A more detailed discussion of the procedure and method of calculation has been published previously.[9-10]

Our study focused on one P4 containment facility, Building 550 of the Frederick Cancer Research Centre (FCRC) at Fort Detrick, Frederick, Maryland. A P4 laboratory is the most stringent containment facility for DNA research. In particular, this study examined the escape routes from Rooms 214 and 215, which contain the Class III cabinet areas of the P4 facility. The facility is undergoing some structural changes, and we obtained detailed architectural drawings of the reconstructed building with the cooperation of the engineering staff at FCRC. The drawings included floor plans, ventilation and piping diagrams, and details of the electrical systems.

The FCRC 'Safety and operations Manual' and FCRC personnel themselves, verified procedures for entering an exiting the facility, experiments, and other operations of the facility. Fig.1 shows a schematic which was developed from the architectural drawings of the air ventilation and liquid modes of transport of materials from Rooms 214 and 215.

Air is supplied to Rooms 214 and 215 from 'clean' areas of the building by fans, creating a pressure differential between these two areas and producing a directional air flow. Supply air is passed through two filters, one low efficiency filter for large particles and one 95% efficient filter. An air pressure difference is also maintained between the room air and the Class III cabinets. Air is exhausted from the rooms and the cabinets through the filters indicated in the diagram.

The sole water inlet to Rooms 214 and 215 is into the Class III cabinets. Before the water enters the facility, it passes through a back flow preventer. No drinking water is available in the rooms, and building drinking water is supplied by a separate line which is tapped off the main line before the water reaches the back flow preventer.

There is one floor drain in each room and several cabinet water drains. Each drain has a minimum six-inch trap and all liquid effluents drain to a common pipe. The liquids are treated by the Fort Detrick Sewage Sterilization Plant, and then by a municipal sewage treatment plant having primary and secondary treatment.

Two additional modes of organism escape were considered after an examination of the facility: contact modes, and natural catastrophes. The contact mode included the human contacts through ingestion, injection into the blood, or transport on skin or clothes, as well as organism contact and escape on any

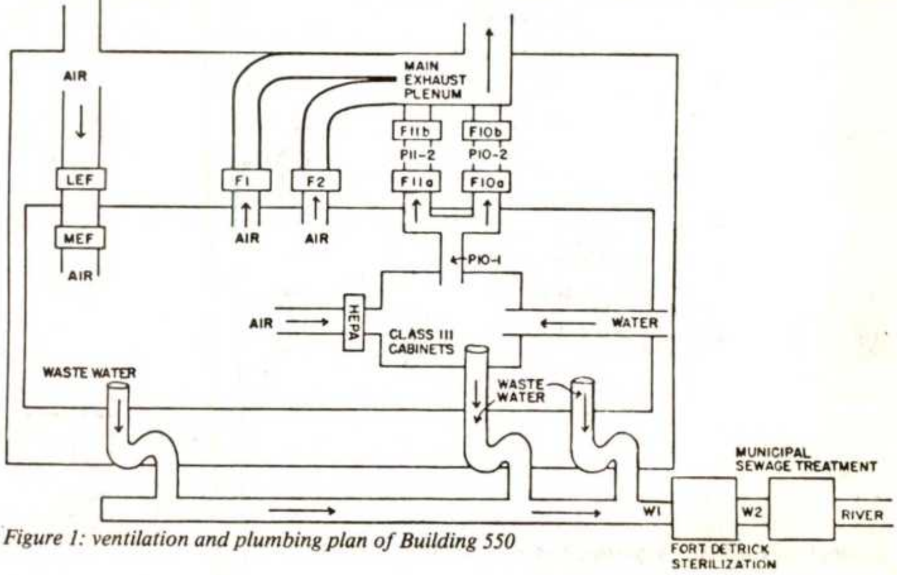


Figure 1: ventilation and plumbing plan of Building 550

0028-0836/79/410422-02$01.00

materials (instruments, glassware, paper, laundry, media, cultures, etc.) which are transported from the facility.

Certain natural catastrophes could occur during the lifetime of the facility which could reduce or eliminate the effectiveness of all containment carriers. These could include earthquakes, major storms and fires. Although the probability of these events may be remote, the probability of escape given the events is very high. Therefore, these escape routes were also considered.

The top event in this fault tree was considered to be "appreciable number of RDNA organisms escape" from the P4 facility. It is recognised that different numbers of organisms would be used in different experimental protocols. In addition, aerosol generation would be likely to be a function of the experimenters' capabilities.[6,7] The survivability of organisms in different media (air, water, solid wastes) would also play a role in determining the likelihood of escape of a given number of organisms. The transit time to the exterior of the facility was considered to be very low with respect to organism survival time.[7] These factors were not considered explicitly in this first application of fault tree analysis to recombinant DNA containment facilities. It should be noted however, that more detailed studies to develop appropriate models and experimental data could lead to an incorporation of these variables in a second generation tree.

The four major escape routes are shown in the fault tree in Figure 2:

- air ventilation transport,
- liquid waste transport,
- contact transport, and
- major catastrophes.

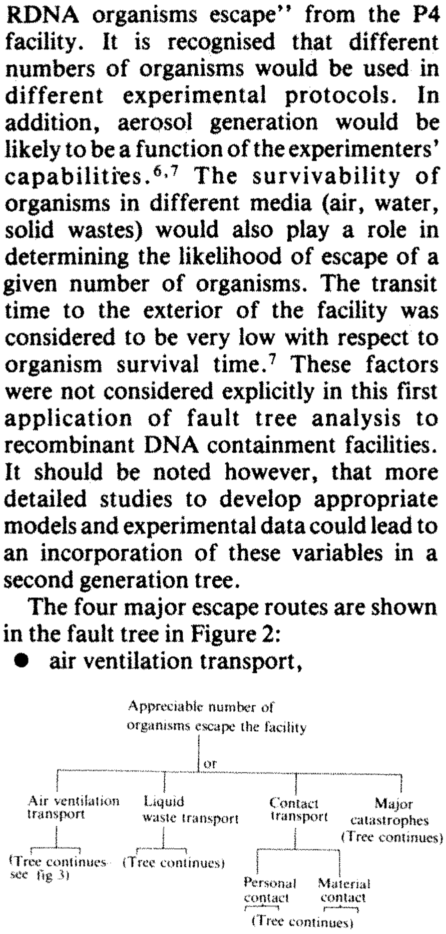

Figure 2: fault tree showing major escape routes

The events leading to air ventilation transport are shown in Fig 3. The primal events (57 in the whole tree) can be found at the bottom of the tree. Details of the complete tree are available from the authors.)

For each primal event there is an associated frequency of occurence, λ, which is the inverse of the mean time interval, in which the event will occur exactly once. The mean time to repair, τ, in the context of fault tree analysis, is the time needed either to repair the fault or to move the system to a safe state. For some primal events, it is easier to assign an unavailability, q, instead of λ, and τ. Unavailability is the probability that a component is not available.

The components of the P4 laboratory have been operational since April 1977, which was an insufficient time period for developing a useful data base of operations. However, similar component designs exist in other industrial applications, and estimates for q, λ and τ were developed after a discussion of the primal events in the fault tree with G.J. Powers, Department of Chemical Engineering, Carnegie-Mellon University. A list of the values used in the base case fault tree is available from the authors. It should be recognised that these values can be updated with experimental data as they become available.

The minimal cut sets were developed from the fault tree by applying the algorithm developed by Powers[10], revealing over 200 potential escape routes. The frequency of each cut set was calculated using our estimates of q, λ and τ with the frequency equations of Powers.[10] In order to obtain the freqency of the top event, the frequencies of the minimal cut sets were summed. The mean frequency of the top event 'escape of an apppreciable number of organisms, was calculated to be once in 15 years.

Figure 3: part of fault tree showing risks through air ventilation

The "importance" of a minimal cut set in a fault tree is defined as the frequency of that minimal cut set divided by the frequency of the top event.[10] This may be interpreted as the probability that the events of a minimal cut set have occurred, given that the top event has occurred. From Table 1, it can be seen that approximately 75% of the escape potential can be attributed to three minimal cut sets. With the top eight cut sets, approximately 95% of the escape potential is accounted for.

Table 1: CUT SET IMPORTANCE

Cut Set	Importance to Escape Frequency
Organism injected into blood	0.383
Filter F11a and F11b failure; filter failure undetected	0.191
Transport container leaks	0.077
Organism inhaled in Rooms 214 and 215; pipe P10-1 failure	0.046
Filter F10a failure; pipe P10-2 failure; filter failure undetected	0.025
Filter F11a failure; pipe P11-2 failure; filter failure undetected	0.025
Appreciable number of organisms in building; major storm	0.023

Table 2: PRIMAL EVENT IMPORTANCE

Event	Importance to Escape Frequency
Filter failure undetected	.473
Organism injected into blood	.383
Filter F10a failure	.217
Filter F11a failure	.217
Filter F10b failure	.191
Filter F11b failure	.191
Transport container leaks	.077
Aerosol generated	.061

The "importance" of a primal event is defined as the sum of importances of every minimal cut set in which the primal event is an element. [10]The potential "weak" links in the containment system are further indentified in Table 2. Of the top six primal events in importance, five involve the high efficiency particulate air (HEPA) filters F10a, F10b, F11a, F11b, F11b, which are located in the exhaust stream of the Class III cabinets. In addition, the event of injecting the organisms into the experimenter's blood by accident is also a significant contributor to the potential for organism release.

The frequency of escape can be modified by changing system and procedural variables. We tried modifications of the parameters of all primal events that appeared in both the set and primal event importance tables (tables 1 and 2). In particular, it was found that changes in the HEPA filter parameters will significantly modify the escape frequency.

In the base case, the mean escape

The authors would like to acknowledge the cooperation of Drs W Emmett Barkley and John Nutter, National Institutes of Health, Washington, DC and the assistance of Orley Bourhard, Everett Hanel, Stanley Nagel and Irv Swope at the Frederick Cancer Research Center.

frequency is once in 15 years, assuming a mean HEPA filter failure rate once every four years. However, if this is decreased to once in eight years, the mean escape frequency decreases to once in 22 years. On the other hand, if the filter failure rate increases to once in two years, the mean escape frequency increases to once in seven years. If the filter mean time to failure detection is reduced from six months to 1.5 months, then the mean escape frequency again declines to once in 22 years. The impacts of other system modifications can be assessed in a similar manner.

We recognise that our fault tree — part of which appears in figures 3 and 4 — does not describe all the system parameters and modifications which may be of interest in a more complete description of escape likelihood from the P4 system. In particular, there remain considerations of:

- a more explicit description of the dependency of the likelihood of escape on the amount of released material, possible concerns that the organism survivability, and therefore potential for harmful impact, may depend on the mode of escape,
- the effect of alternative experimental protocols on the escape risk, and
- inclusion of experimental data on λ, τ, and q for system components. In addition, further examination of the fault tree for common mode failures would be useful. It is intended that future studies will reduce some of these presently perceived deficiencies.

This study does not describe whether our calculated escape frequencies pose a significant risk. The probability of a harmful consequence is the product of several probabilities involving biological details of the recombinant organisms and their escape probability. Further studies would be needed in order to determine whether or not a P4 laboratory provides an "acceptable" risk. □

Full steam ahead to save Kenya's fuel

Rift Valley gushers, courtesy of the Kenya Power Company

HARD-pressed by the rising price of oil and a growing shortage of fuelwood, Kenya, like many developing countries, badly needs alternative sources of energy. Fortunately, it has at least one: a huge natural reservoir of boiling hot water some 1,000 metres beneath the Rift Valley about 80 kilometres from Nairobi.

Interest in the area as a possible site for a geothermal power station began in the 1950s, but detailed exploration (financed by the United Nations Development Programme) did not begin until 1970 when four wells were drilled in a wild, semi-arid area known as Olkaria, about five kilometres south of Lake Naivasha. Eleven wells have now been drilled there, and a contract was recently placed for construction of the first 15 MW power station which will feed into the national grid by mid-1981.

The Olkaria Power Station will be the first full-scale geothermal power station in Africa (a 220-KW plant was installed in Zaire at a metal mine in the 1950s, but was costly and inefficient and was closed down with the mine). When Olkaria goes into operation, it is expected to supply about 5% of Kenya's electrical power. Another 15MW generator is planned for operation in late 1982, and the station's capacity will be expanded to reach 90 MW in the next 10 years. Total energy available from the reservoir has been estimated at 170 MW for 25 years.

Kenya has no known fossil fuel resources, and the rising cost of imported oil recently prompted the President, Daniel Arap Moi, to call for reduced consumption. But as T.S. Tuschak, a Canadian energy consultant currently on loan to the Kenya government through the UNDP, pointed out recently (July 5, page 2) savings in the essential sectors can at best be 7%, and consumption by private transport can only be reduced by about 10%.

Kenya's economy is divided into two sectors: the industrialised and the rural. The industrialised sector gets about 85% of its total energy supply from oil, the rest from hydroelectricity. The rural economy's energy source is almost 100% wood or charcoal. And while Kenya has not suffered as much as some countries from deforestation, a fuelwood shortage is likely and has already occurred in some areas. Population is increasing at 3.9% a year, causing not only increased wood consumption but declining land availability. Fuelwood consumption is currently 20 million tons annually.

The government's forestry department has introduced conservation and reafforestation programmes and has shown some interest in agroforestry, and public attention has been drawn by various groups to the advantages of tree-planting. But it is not possible to wean the mass of the population away from its reliance on wood as its principal source of energy.

Kenya's unused hydro-electric power potential is 600-700 MW. Total electricity demand, which has grown at 8-9% per annum and is expected to continue at that rate for the balance of the century, should reach 1200 MW by AD 2000. This would call for 1500-1600 MW installed capacity. Development of all the HEP potential together with the present installed capacity of about 400 MW would leave a gap of 400-500 MW. The total geothermal resource is believed to be between 170-500 MW which could fill that gap.

Kenya has so far evolved no rural energy policy. While there are arguments for and against rural electrification schemes in developing countries, Mr Tuschak believes that an increase in electrical consumption in certain areas of Kenya could reduce its growing consumption of wood.

"In my estimation there are about 1-1.5 million people in the rural sector who are better off in financial terms and can afford to pay for commercial energy, or at least part of the cost," he told *Nature*. "Many of these people have already requested electricity and others would be happy to have it. If they are supplied with electricity they will stop consuming wood, and Kenya could perhaps cut down wood consumption by 10% or more".

Although hydro stations provide most of Kenya's electrical energy at present, hydro generation is expensive to run because the country's rivers have highly variable seasonal flow. Capital costs are also high. Under such conditions, geothermal plants offer an economic supplement.

Spanish science: underfinanced and over centralised

SIR, — The uncertainty which research is suffering in Spain was briefly reviewed in a recent issue of *Nature* (9 August, p438). In the meantime we are approaching collapse.

In the last decade most research groups were supported by three-or four-year grants administered by the Comisión Asesora de Investigación Cientifica y Técnica. These grants are essential to cover running expenses as well as contracts for young scientists waiting for a stable position. The last distribution of grants took place in 1977 and all grants presently in existence terminate in December 1979. No new distribution scheme has been publicised, so that up to this moment we do not know the 1980 situation.

Even if a distribution of grants is announced in the next few weeks, processing them will take several months. Under these circumstances many scientists are forced to leave the country. Only emergency action will stop irreversible damage to research in Spain: namely, to extend automatically current grants for one year more.

The Ministy of Universities and Research is certainly preparing a three year plan (1980-1982) for the development of research in Spain. We are all eagerly waiting for its guidelines, but time is running short.

Another stumbling block in the development of research in Spain is its continuing centralism. A clear example is the Spanish Research Council (CSIC). Over two thirds of its activities and scientists are located in Madrid, with even a larger fraction of its budget concentrated in Madrid. This fact prevents a rational development of research elsewhere in Spain, close to places (industry, agriculture) where it is most needed.

In 1977, 187 new positions for scientists were provided; 70.6% of them were awarded to Institutes in Madrid. Presently another 198 new permanent positions are in the process of being provided; again over 60% of them will be for Institutes in Madrid. These numbers are not trivial, since the new positions mentioned represent 28% of the total permanent positions of the Spanish Research Council.

A peculiar geography of science has arisen through the years: there is not a single research institute in the Basque country, there are more Catalan biochemists working for the CSIC in Madrid than in Barcelona, there are more Catalan physicists working for the French CNRS than for the Spanish CSIC . . . This trend needs urgent modification. Drastic preference for new positions should be given to new and existing groups located in other areas of Spain.

At present a lack of funds and guidelines, together with the maintenance of centralism are producing irreparable damage to the development of research in Spain. We very much hope that the announced three year plan may open a brighter future.

Yours faithfully,

JUAN A SUBIRANA

Egyptian science

SIR, — I must comment on the article by Ziauddin Sardar (2 August, page 350).

"Divided and uncertain" does not reflect the reality of the Egyptian scientific community. As a scientist, and science editor for *Al Ahram* for the last twenty years, I will try to be objective, realistic and frank. The Egyptian scientific community, the biggest in the Arab world and Africa by any measure, is not divided regarding scientific cooperation with Israel. Instead the majority are for international scientific cooperation which they are practising all over the world in spite of shortcomings, drawbacks and loopholes in Egypt; and regardless of the sufferings of scientists and lack of stability and funds due to continous wars which have drained and exhausted our already depleted resources. Cooperation with Israel, on what basis?

In the meantime the powerful Israeli scientific community is silent and negative regarding the dangers threatening the peace process, mainly the insistence of the Israeli politicians and policy makers on depriving the Palestinians — including the scientific community — from their legitimate human rights to live in peace in their homeland. The Israeli scientific community is meanwhile raising hell against the Soviets for injustice against some individual Jewish scientists.

To be frank, the Egyptian scientific community does not like or agree with the Israeli superiority complex, the assumption that Israel is the only cradle of science and technology in the Middle East, and that it is an oasis of development and civilisation in a desert of backwardness inhabited by ignorant Arabs, including the Egyptians. Not bearing in mind the colossal funds and previleges Israel is getting from the US and other rich Jewish communities, the Israeli scientific community must realise and recognise that Egyptian scientists — inside Egypt and the brain-drained Egyptian scholars in the US, Europe and other Arab countries — are competent despite all the shortcomings. Unless confidence prevails, signed treaties will not help either Israeli or Egyptian scientific communities. We in Egypt refuse the Israeli arrogance in science and technology, including the assumption that Israel will teach the Egyptians and lead them to prosperity. Egyptians are certain (and not uncertain as Mr Sardar says) that comprehensive and just peace must include the Palestinians who have one of the highest rates of education of scientific personnel in the area, and we need their cooperation too, to build peace.

The Egyptian scientific community is certain and undivided about one thing: Egypt will still be part of the Arab world and cannot substitute Israel for Arabs, not only for religious, moral, ethical and historical reasons, but for practical, economic and psychological reasons too. The Arab world is the area where the Egyptian scientific community is practising and will continue to practise its human superiority, and make money too. This cannot be fulfilled in the cooperation with Israel.

Regarding Nechemia Meyer's article "Israel: a one sided love affair", I quite agree with the title but not with the content. The negative response to the willingness of the Israeli scientific community to enter into bilateral relations with Egyptian insitutions and the story of the experience of the Israeli scientists in Egypt is very normal. As long as the Israeli politicians and policy makers still insist on flagrantly depriving the Palestinians of their right to live peacefully in their homeland, and the negative attitude of the powerful Israeli scientific community continues, the chance of Egyptian-Israel scientific cooperation will be very marginal and meagre. Cooperation cannot be enforced by treaties, especially between scientists. Cooperation can start only when confidence is prevailing — and this is not the case yet. The Egyptian scientific community is part of Egypt, with all its aspirations for a just and comprehensive peace for Egyptians, Israelis and Palestinians.

Yours faithfully,

SALAH GALAL

Cairo

Highlighting persecution

SIR, — Dr Lorch (13 September, page 98) is right to emphasise the large themes of international solidarity. Vera Rich has from time to time highlighted smaller, but not unimportant, instances of persecution of individual scientists. Her facts are sometimes incomplete, but aren't they hard to come by? If Dr Lorch finds it easy, perhaps he would find out why the Fields Medallist Gregory Margoulis was not permitted to attend the Helsinki Congress of Mathematicians. Some of your readers would like to know.

As to the USSR relying on its own scientists, Dr Lorch will find an interesting example of masochistic circumcision if he looks at the USSR reproduction of *J. Chem.Soc.Faraday Transactions* II (69) 1973 page 1104; it deals with the . . . Dogonadze theory. The missing name is Levich.

Yours faithfully,

H. KESTELMAN

University College, London

Decentralising science

SIR,—This area is exactly such as you have in mind in your editorial 'Another sort of brain drain' (13 September). Apart from the excellent Agricultural Department at Aberystwyth 60 miles away, scientific and technological activity here is confined to teaching and the handful of people required to run the three oil refineries and the power station in Milford Haven.

Yet these massive capital intensive plants frequently find their way into lightly populated rural areas of the country, and could serve as a focus for a far more developed scientific community — enjoying incidentally lower establishment cost and infinitely preferable environmental regimes. It may not be fashionable or desirable to adopt the scientific cities of Soviet Siberia: but everyone would benefit from a sensible decentralisation of scientific work — not least from the elimination of time loss and stress inherent in daily travel to virtually any location in South East England.

Yours faithfully,

DAVID GREEN

Patterns in the abundance of parasites on plants

from Robert M. May

What determines the total number of parasitic species to which a particular species of genus of plants is host? This question—with 'parasite' interpreted broadly to range from herbivorous insects to fungi—has lately attracted much attention.

A primary factor is the geographical range of the host plant, with greater range implying more parasite species. As reviewed by Southwood (*Colloq. Int. du C.N.R.S.* **265,** Comportement des Insectes et Milieu Trophique, 471; 1977) and Strong (*A Rev. Entomol.* **24,** 89; 1979), various studies have shown that the logarithm of host-species range accounts for some 20-60% of the variation in the number of host-species for a panoply of associations including insects on trees in Hawaii, Britain and Europe, leaf miners of oak in California, gall-forming wasps on oaks in North America, arthropod pests of tea, cacao, and sugarcane, diseases of crops in the continental United States, and parastic fungi of British trees and North American plants. Three recent papers go beyond this, seeking to understand the causes of the residual variation in 'species richness' of parasites, after such 'species-area' effects are factored out: Strong and Levin (*Amer. Nat.* **114,** 1; 1979) analyse an eclectically compiled array of data on the insect associations of 214 genera of British plants and on the fungal parasites of 323 species of US plants; Lawton and Schroder (*Nature* **265,** 137; 1977) examine the insect fauna of some 70 species of British herbs and shrubs; and Lawton and Price (*J. Anim. Ecol.* **48,** 619; 1979) deal with the narrower group of larval agromyzids that mine the leaves and stems of some 60 plant species in the family Umbelliferae in Britain.

Strong and Levin divide the plants into trees, shrubs and herbs. They show that there is no significant difference among these three categories in the way species richness of parasites increases with geographical range of the host plant, but that trees systematically tend to have more parasitic species than do shrubs, which in turn have more than herbs (per unit area of geographical distribution). More precisely, their 31 genera of British trees have an average of 28 species of insects, 40 genera of shrubs average 10 insect species, and 143 genera of herbs average around 5 insect species. The number of species of parasitic fungi average around 15 for their 127 species of North American trees, 7 for 70 shrub species, and 5 for 126 herb species. Lawton and Price classify their umbellifers according to the mean physical size of the plant (the geometric mean of the normal maximum and minimum heights of mature plants, as given in Clapham, Tutin and Warburg's *Flora of the British Isles)* and according to leaf form; these are both measures of the 'architectural complexity' of the plant. They will find that species-area effects account for 32% of the variance in species richness of mining insects, and that plant architecture explains some 20% of the remaining variance.

Within any one of their three growth-form categories, Strong and Levin find that most further comparisons reveal no discernible differences in species richness of parasites. Thus American conifers and flowering trees support roughly the same number of species of parasitic fungi, and grasses do not differ significantly from herbs in general. Likewise, British monocots, grasses, aquatic and bog plants, sedges and composites do not differ discernibly from herbs in general in the number of insects species they support per unit host range. Classifying the host plants by life-history strategy, Lawton and Price were unable to determine any significant difference in the number of agromyzid species associated with annual, biennial or perennial umbellifers; in this repect the umbellifers resemble European Cynarae (Lawton and Schroder, *Proc. IV Int. Symp. Biol. Control of Weeds,* ed. T.H. Freeman, University of Florida Press, 1978). Two comparisons within the herb-shrub-tree categories do, however, show differences; ferns support fewer insect species than do other herb genera in Britain; and weedy herbs support fewer fungal parasites than do climax and subclimax herbs in the US. I shall return to these two points below.

Strong and Levin summarise their results by proposing "that the greater size and morphological complexity of trees than shrubs, and than herbs in turn, account for these patterns in pest species richness; larger more complex hosts present a greater diversity of pest niches". This matches with Lawton and Schroder and with Lawton and Price's suggestion that plant 'architecture' is a significant component in accounting for patterns in the number of parasitic species, a theme which is further explored in several of the papers in the Special Symposium on Insect Diversity held in 1977 by the Royal Entomological Society (see the chapters by Southward, Lawton and May in *Diversity of Insect Faunas,* eds Mound & Waloff, Blackwell, 1979).

The finding that ferns support fewer species of parasites than do other herbs can be challenged on the grounds that the fauna of ferns are typically less well studied than those of seed plants. But a meticulous study of the invertebrate fauna of the fern *Pteridium aquilinum,* or bracken, in Britain (Lawton *Bot. J. Linn. Soc* **73,** 187; 1976) suggests that ferns do indeed possess a relatively impoverished fauna of insect pests; adjusted for its range in Britain, bracken does not have a rich pest fauna relative to other herbs, even with Lawton's extremely complete data. Lawton's study encompasses the chemistry of bracken, suggesting it has five distinct modes of chemical protection. It may be that ferns generally possess a greater diversity of biochemical defences than do other herbs, which affords them relative freedom from pests.

The conclusion by Strong and Levin that weedy herbs tend to have fewer fungal parasites than other US herbs is supported by Lawton and Schroder's finding that weeds and other annuals tend to have fewer insect pests than perennial herbs. This tendency is, however, not manifested among Lawton and Price's umbellifers. Moreover, the data for fungal species on weedy herbs is very noisy, in the sense that the species-area regression accounts for only 12% of the variance (in contrast to 30-50% for other herbs, shrubs and trees). The question is further clouded by the fact that the man-made disturbances, which have greatly increased habitat for weeds and spread them so widely throughout the US, have mainly occurred only over the

---

0028-0836/79/410425-02$01.00

past 200 years. All this is a pity, as patterns in the relative number of parasitic species associated with weedy herbs could shed light on Feeny's *(Rec. Adv. Phytochem.* **10**, 1; 1976) ideas about plant 'apparency'. According to this hypothesis, 'apparent' plant species (which are large, more long-lived, and tend to occur later in succession) are "bound to be found" by herbivores; they therefore need general (quantitative) defences that reduce digestion in herbivores and that cannot easily be breached by the ability of parasites to evolve resistance to plant-produced poisons. Conversely, ephemeral or 'inapparent' plants emphasise reproduction and dispersal, and minimise the metabolic cost of defence against herbivores by use of (qualitative) poisons that are effective in small doses. It is not clear what these ideas imply for the correlation between species richness of parasites and host plant 'apparency'; as Strong and Levin observe, "The null hypothesis that chemical differences do not result in different numbers of parasite species for plant taxa should be tested. One way of doing this might be to look for patterns within residuals about the pest species/host area regression line for each growth form". More work is needed before any generalisation can be made here.

In short, something like 50% in the variance of species richness of parasites among host plants can typically be attributed to the geographical range and architectural complexity of the host. Strong and Levin, and Lawton and Price, advance various suggestions about the other 50%. Lawton and Price favour the idea "that the subtle accumulation of specialists (e.g.miners and gall formers) may continue over very long periods of evolutionary time". This could result in much variability if their 60-odd agromyzid-umbellifer associations were at many different stages along the road to eventual equilibrium. Most of the evidence, however, suggests that the total number of parasite species on host taxa usually reaches an asymptote within short periods of evolutionary time (see for example, Gilbert in *Analysis of Ecological Systems*, eds Horn, Mitchell & Stairs, Ohio University Press, 1979); Strong, *op. cit.* 1979). Other explanations for the residual variability include incomplete knowledge of the parasite fauna, differences in the abundances of plant species of equal geographical range (common plants could well have more species of parasites than rare ones, geographical ranges being equal), and variation in the efficiency of the plant's biochemical defences. On top of all this is the possibility, recently and cogently emphasised by Simberloff and others, that substantial differences arise from historical and evolutionary accidents, and have no discernible deterministic cause.

Stepping away from the details, we can see these thoughtful and technically sophisticated studies as a paradigm of much of the contemporary search for patterns in ecosystems. Depending on one's cast of mind, one can derive pleasure from the systematic explanation of roughly half the variability in the number of parasite species on plants, or pain from that half of the variability that remains unexplained. □

Dissecting the red cell membrane skeleton

from Samuel E. Lux

To survive in the circulation red blood cells must be both durable and flexible: durable enough to withstand the turbulent cardiac passage and flexible enough to negotiate the narrow portals of the spleen. These dual demands are the responsibility of a submembranous protein network which functions as a 'membrane skeleton'. Because defects in this structure are probably responsible for a number of important haemolytic anaemias (see Lux *Semin. Hematol.* **16**, 21; 1979 for a review) and because it is a model for cytoskeletons of more complex and less accessible cells, a great deal of effort has been expended dissecting and reassembling the skeleton of the human red cell. This analysis is currently proceeding at an exceptional pace and seems, at last, to be leading to a comprehensible picture of skeletal anatomy.

Definition of the membrane skeleton

Operationally, the membrane skeleton is defined as the insoluble residue which remains after extraction of intact red cells or their isolated membranes with the nonionic detergent Triton X-100. Under the electron microscope this structure is an anastomosing network of twisted, irregularly oriented microfilaments dotted with globular protrusions (Hainfeld & Steck *J. supramolec. Struct.* **6**, 301; 1977; Liu *et al. Fed. Proc.* **7**, 1508; 1978). It comprises about 60% of the membrane protein mass and includes all of the spectrin (bands 1 and 2), actin (band 5), ankyrin (bands 2.1, 2.2, 2.3 and 2.6) and band 4.1; and a portion of the proteins designated bands 3, 4.2, 4.9 and 7 (Fig. 1). Spectrin, actin and bands 4.1 and 4.9 form the core of the structure since the skeleton retains its shape and structure when the other components are eluted with hypertonic KCl (Sheetz *Biochim. biophys. Acta,* in the press) but disintegrates if either spectrin or actin are removed (Sheetz *J. Cell Biol.* **81**, 266; 1979).

Spectrin structure

Spectrin, the major skeletal protein (60 to 75% by weight), is composed of two enormous subunits, bands 1(molecular weight 240,000) and 2 (220,000) which are structurally similar but are not identical (Anderson *J. biol. Chem.* **254**, 939; 1979). The protein has been intensively analysed since its discovery by Marchesi and Steers more than a decade ago (*Science* **159**, 203; 1968). In the past few years purified spectrin heterodimers (band 1+2) and heterotetramers (band $1+2)_2$ have been isolated and sized (Ralston *Biochim. biophys. Acta* **455**, 163; 1976; Kam *et al. Biochemistry* **16**, 5568; 1977), the equilibrium relationships of these molecules have been defined (Ungewickell & Gratzer *Eur. J. Biochem.* **88**, 379; 1978), and the tetramer has been identified as the physiological species. However, because spectrin has unusual hydrodynamic properties and is difficult to see in the electron microscope, two of the most critical pieces of information — the shape and molecular conformation of the molecule — have resisted definition. Fortunately, Shotton, Branton and their colleagues (*J. molec. Biol.* **131**, 303; 1979) have recently discovered that spectrin's molecular outlines can be captured in platinum-carbon replicas formed by low-angle shadowing. These molecular casts clearly show that spectrin dimers are long (~1000 Å), slender (~ 50 Å), worm-like molecules in which the two subunits are aligned in parallel and variably coiled about each other. Individual molecules assume many different conformations and must be quite flexible — a property which may be critical for normal membrane pliancy. Spectrin dimers join end to end to form tetramers, but high order oligomers are not seen. This confirms the work of Ralston and Kam noted above and indicates that the dimers join head to head instead of head to tail, since, in the latter alignment at least some hexamers, octamers, and so on, should be formed. Because spectrin subunits seem to be tightly attached at their extremities, Shotton postulates that complementary sites exist at the ends of each of the sister subunits and suggests that the dimer-tetramer interconversion simply involves a reorientation of the sites at the heads of two neighbouring dimers so that each subunit pairs with its sister chain on

the adjacent dimer. This is an attractive hypothesis since the cleavage of existing bonds (the first step in the dimer–tetramer interconversion) could account for the unusually high activation energy of the process (Ungewickell & Gratzer *op. cit.*).

The spectrin-actin-band 4.1 complex

If pure spectrin dimers can only associate to tetramers, then clearly other molecules are required to form the basic skeletal framework. Their identification has been approached in two ways: by dissection and reassembly. Sheetz finds he can strip away all of the skeletal proteins except spectrin, actin and bands 4.1 and 4.9 and still retain an intact skeletal substructure. This suggests that one or more of the latter three proteins provides the critical cross-linking function. Studies reported recently in *Nature* (**280**, 811; 1979) confirm this postulate. Ungewickell and his colleagues observe that mixtures of purified spectrin tetramer, polymerised actin (F-actin) and band 4.1 combine at physiological ionic strengths into pelletable ternary complexes and, in some cases, gel. No complexes are formed from binary mixtures of these proteins or from ternary mixtures if the actin is unpolymerised (G-actin). Electron micrographs of isolated complexes show F-actin filaments bridged by fine curved fibrils which presumably represent spectrin tetramers. The pictures suggest the actin-binding regions of the tetramer are near the distal (tail) ends of the molecule. Dimeric spectrin attaches to actin filaments but, being monofunctional, is unable to cross-link them.

Independent evidence from several other laboratories largely corroborates this picture. Fowler and Taylor (*J. Cell Biol.* **79**, 222a; 1978) have reported that oligomeric complexes of spectrin, actin and band 4.1, extracted from red cell membranes cause actin to gel and that purified spectrin dimers or tetramers lack this activity, suggesting a requirement for band 4.1. More recently (personal communication) they discovered that this effect can be mimicked simply by adding purified tetramer and band 4.1 to actin solutions. Interestingly, they find the reaction is maximal at physiological concentrations of calcium (10^{-7}–10^{-8} M), which may explain, at least in part, the deleterious effects of this ion when it accumulates in red cells. At lower ionic strengths, Cohen and his coworkers (personal communication) observe that purified spectrin induces actin gelation in the absence of detectable band 4.1 and Tyler and Branton (*Proc. natn. Acad. Sci. U.S.A.*, in the press) report that purified band 4.1 binds to spectrin in the absence of actin, indicating that stable binary complexes can exist under certain circumstances. Electron micrographs of spectrin–4.1 complexes show that the binding site of band 4.1, like that of actin, is located near the tail of the spectrin dimer.

These studies are all consistent with a skeleton composed of long, flexible, bifunctional, spectrin tetramer strands cross-linked at each end through interactions with actin and band 4.1 (Fig. 1). While this model of the skeleton is greatly advanced compared to earlier renditions, many important questions remain. For example, what is the state of the actin? The experiments of Ungewickell *et al.* and observations of Brenner and Korn (*J. biol. Chem.* **254**, 8620; 1979) indicate that actin must be polymerised to complex with spectrin. But actin filaments are not visible in electron micrographs of red cell membranes and the amount of actin present (about four molecules per spectrin tetramer) is not compatible with the existence of long actin filaments. This leads to the conclusion that actin must exist in short filaments or 'protofilaments' (Cohen & Branton *Nature* **279**, 163; 1979; Ungewickell *et al. op. cit.*), and, by extension, implies that some mechanism must exist to limit the extension of such filaments. The point is by no means settled however, since there is evidence that oligomeric complexes of spectrin, actin and band 4.1 may contain some G-actin (Ralston *Biochim. biophys. Acta* **510**, 283; 1978). Nevertheless, at present it seems likely that much of the actin in the skeleton is organised as short filaments. If true this leads to other questions. Are all these filaments the same size? Are the number of spectrin tetramers which branch from the filaments constant or variable? In the model shown in Fig. 1, I assume that variable numbers of spectrin molecules are joined by actin filaments of variable length. This hypothesis would explain the disordered organisation of the skeleton seen by electron microscopy, but other explanations are also possible. For example, the disorder could simply be due to the inherent flexibility of the spectrin molecules. Alternatively spectrin may have multiple binding sites for actin and/or band 4.1 near its distal end which are variably filled.

The spectrin-ankyrin-band 3 complex

The interaction of the red cell skeleton with the overlying lipid bilayer is better understood than the organisation of the skeleton itself, thanks largely to a series of elegant studies which originated in the laboratory of Daniel Branton at Harvard. The story began with the observation that the red cell contains about 100,000, high affinity (K_D = 10^{-7} to 10^{-8} M) binding sites for spectrin on its inner surface (Bennett & Branton *J. biol. Chem.* **252**, 2753; 1977). Subsequent chapters revealed that each of the sites resides in a 72,000 molecular weight chymotryptic fragment (Bennet *J. biol. Chem.* **253**, 2292; 1978), that antibodies to this fragment label only bands 2.1 and 2.2 (Bennet & Stenbuck *J. biol. Chem.* **254**, 2533; 1979), and that peptide maps of these two bands and bands 2.3 and 2.6 are homologous with the 72,000 molecular weight piece (Luna *et al. J. biol. Chem.* **254**, 2526; 1979; Yu & Goodman *Proc. natn. Acad. Sci. U.S.A.* **76**, 2340; 1979). This suggests that the lower molecular weight piece (Luna *et al. J. biol.* products of the parent band 2.1 molecule. At present it is uncertain whether they are formed in intact red cells or are an artefact of membrane preparation.

Band 2.1 and its progeny have been variously named ankyrin (Greek, anchor), nectin (Latin, to connect), and syndein (Greek, to bink together). Ankyrin was chosen first, but because this name had already been given to a plant protein and because it soon became clear that ankyrin was not the true anchor (see below), the protein was rechristened nectin. Unfortunately this name was also a duplicate, so a second change to syndein was made. Some of those working in the field continue to use ankyrin while others have adopted the revised terminology. Presumably the rest of us will have to choose between these appellations (I prefer ankyrin) or make up our own, at least until some Commission on Nomenclature decrees.

In the latest sequel to this saga (*Nature* **280**, 468; 1979), Bennett and Stenbuck report that ankyrin is firmly linked to band 3 in detergent extracts of spectrin-depleted red cell membranes. (It should be noted that some band 4.2 is also associated with band 3 in these extracts. The data presented favour the author's interpretation of a direct linkage between ankyrin and band 3, but do not completely exclude the possibility that band 4.2 is interposed between these two proteins). The band 3 molecules involved (10–20% of the total) are apparently identical to the principal band 3 protein which functions as an anion exchange channel. Unlike ankyrin this protein spans the lipid bilayer and is presumably the true site of skeletal anchorage. Ankyrin is thus not an anchor but an anchor chain — a protein that links spectrin and band 3. In fact it may function generally to connect cytoskeletal elements and integral membrane poteins since, unlike spectrin (see below), it is apparently present in many types of cells (Bennet & Stenbuck *op. cit.*).

The electron microscopic techniques used to visualise the band 4.1 binding site have also been applied to ankyrin (Tyler & Branton *op. cit.*) and are even more successful since ankyrin is a larger molecule (a 80 Å × 95 Å pyramid) than band 4.1 (a 60 Å sphere). These studies clearly show that ankyrin binds to a site 200 Å distal to the end of spectrin involved in the dimer-tetramer interaction. The stoichiometry of this linkage (whether there are one or two ankyrins per tetramer) remains to be determined.

Membrane skeletal model

Taken together, this information provides a fairly clear picture of how the principal skeletal proteins are probably organised (Fig. 1). Certain general points remain to be established (for example, the stoichiometry of the spectrin-actin-band 4.1 and spectrin-ankyrin-band 3 complexes and the physical state of actin), and many structural details must still be pursued, but the general framework appears to be taking shape. It must be emphasised however, that the true skeleton is undoubtedly more complicated than the model shown in Fig 1. Skeletal proteins like bands 4.2, 4.9 and 7 are not included in the model since too little is known about their location and function. Band 4.1 must attach to the bilayer in some way since most of it remains on the membrane when spectrin and actin are extracted at low ionic strength. And spectrin chains must often cross each other since the average spacing between ankyrin-linked band 3 dimers (~375-530 Å) is considerably less than the average length of a spectrin tetramer (~2000 Å).

Halley's Comet in ancient history

from David W. Hughes

RECENT books on comets state categorically that the first definitely recorded return of Halley's comet was that of 240 BC, some adding as a postscript that there is a vague possibility that comets described in 613 BC and 467 BC may also have been P/Halley (the P/prefix indicating a periodic comet). It now seems, however, that observations go back considerably further. Y. C. Chang of the Purple Mountain Observatory, Nanking, China finds that the earliest astronomical record of the comet in the historical annals of his country described the apparition of 1057 BC. Reasons for this assertion, together with other early Chinese observations, are published in Chang's recent paper in *Chinese Astronomy* (**3**, 120; 1979) (a translation of *Acta Astr. Sinica* **19**, 109; 1978).

The problem of recognising the historical record as a description of Halley's comet has been approached in two ways. The first relies on celestial mechanics to produce an accurate analysis of the orbital evolution of the comet. Chang started with the position and velocity vectors of Halley's comet and the eight major Solar System planets for a specified epoch (Julian day 2430000.5). The cometary results were taken from Brady and Carpenter (*Astr. J* **76**, 728; 1971) who based their findings on 3085 observations of P/Halley made by 60 observatories over an unbroken period of 20 months during the 1910 return.

The equation of motion of the comet around the Sun was then integrated, taking into account gravitational perturbations by the planets. This enabled the perihelion passage times and orbital elements of P/Halley to be established for the previous 3000 years. So Chang knew when and where in the sky the comet would have appeared. The planetary perturbations produce changes in the orbital period of the comet, which was for example about 72.9 years between 762 BC and 689 BC, and as long as 79.7 years between AD 1222 and AD 1301. The inclination of the orbit has decreased by about 1.5° over 3000 years, and during this time the argument of perihelion has changed from 77° to 112° and the longitude of the descending node from 18° to 58°. A more important parameter is the maximum brightness of the comet. This seems to change by about 2.7 magnitudes per millennium, indicating that P/Halley will reach a maximum magnitude about +0.5 at its next apparition in 1986, whereas it was about −7.7 in 1057 BC — brighter than any of the planets.

Brady (*Pub. Astr. Soc. Pacific* **83**, 314; 1972) also studied the orbital evolution of P/Halley and suggests that the present planets could not account for all the observed changes. To overcome this difficulty he predicted the existence of another planet at a distance of 64 astronomical units (AU) from the Sun, with a mass three times that of Saturn. Chang does not confirm this hypothesis and finds that the known planets account for the observed perturbations. Some astronomers have also proposed that there is a cloud of comets about 50 AU from the Sun having a total mass similar to that of the Earth. Even though P/Halley, with its aphelion distance of 35 AU, would spend a considerable time near this cloud, Chang again finds that such a cloud is unnecessary when it comes to accounting for the perturbation of P/Halley.

Chang's second approach was to peruse the Chinese astronomical records, the most complete historical records in existence, for accounts of Halley's comet. The new account came to light in a chapter on military strategy in the *Book of Prince Huai Nan*. This recounts how a comet was seen in the east with its tail pointing to the northwest at the time when King Wu marched on Zhou of Yin. The book also gives the position of Jupiter at that time. There are three schools of historical thought about the time of Wu's campaign, favouring 1122 BC, 1075-1055 BC or 1027 BC. All agree however, that it occurred in the first two months after the winter solstice. By combining these factors Chang concluded that the campaign and the observation of Halley's comet took place in the winter of 1058/57 BC, so our next observations of P/Halley in 1985/86 will not be the thirtieth, as previously thought, but the forty-first recorded apparition.

are phosphorylated in the intact red cell (Plut *et al. Eur. J. Biochem.* **82,** 333; 1978). Both cyclic AMP-dependent (ankyrin, bands 4.1, 4.9 and 7) and cyclic AMP-independent (spectrin, band 3) kinases are involved. In spectrin, the best studied example, four sites are labelled in a cluster near one end of the band 2 subunit (Harris *et al. Fed Proc.* **37,** 1507; 1978; Anderson *op. cit.*). This is probably the end of the molecule where actin and band 4.1 bind since interactions between actin and crude spectrin preparations are phosphorylation dependence in more purified systems (Brenner & Korn *op. cit.*; Cohen & Branton *op. cit.*). Nevertheless, Pinder's results strongly suggest that phosphorylation does modulate spectrin-actin-4.1 interactions in some way. Presumably it is also functionally important to the other phosphorylated skeletal proteins. Deciphering these functions and how phosphorylation affects them is probably the major unsolved issue in the field.

Evolution

Spectrin (and by implication a spectrin network) is present in all mammalian and avian red cells but has not been detected in other cell types. Pinder and her associates have even found a spectrin-like molecule, immunochemically homologous to human spectrin, in red cells from primitive invertebrates *(FEBS Lett.* **92,** 278; 1978). This implies that spectrin has evolutionarily critical functions and, since its only known functions relate to the membranes vesiculate frenetically when evolutionarily critical structure. This is understandable from the chauvinistic perspective of the spectrinologist; red cell membranes vesiculate freneticlly when spectrin is genetically absent (Greenquist *et al. Blood* **51,** 1149; 1978) or purposely removed and presumably have required support from their inception. What is not clear is how other cells survive without it! Perhaps analogous proteins have evolved to stabilise their membranes but, if so, they remain to be identified. Alternatively nonerythroid cells may have found their ubiquitous cytoskeletal scaffolding sufficient for membrane support while red cells, anxious to discard their intracellular organelles to accommodate haemoglobin, were forced to invent spectrin. Whatever the reason, it remains a mystery (at least to me). □

Genetic approaches to neurobiology

from Gilbert S. Omenn & John P. Blass

THE concepts and techniques of genetics are being wedded to those of the neurosciences with increasing success. Studies of genetically defined lesions in invertebrates, mice, humans, and cultured cells are providing descriptive and pathogenetic information about complex brain functions and behaviours. Several productive new lines of research at this interface were reported at an International Society for Neurochemistry (ISN) meeting in Greece*.

Deliberate construction of mosaic or mutant mice now offers a powerful way to investigate models of human disorders and to distinguish whether dysfunction is intrinsic or extrinsic to the nervous system or muscle. B. Mintz (Institute for Cancer Research, Philadelphia), who pioneered the use of allophenic mice (formed by agregating cells from two 8-cell embryos from two different pregnant mice, hence tetraparental), has constructed such mice using mouse teratocarcinoma (TC) cells in place of one pair of parents. The TC cells serve as a remarkable vehicle for introduction of specific marker or mutant genes, obtained by any of the techniques of somatic cell genetics including mutagen treatment and selection, recombinant DNA techniques, and cell fusion. Mintz has created an $\text{HGPRT}^-/\text{HGPRT}^+$ mosaic mouse from a normal embryo plus HGPRT^-TC cells. Completely HGPRT^- progeny generated from these mice will be the first true animal model for the fascinating and perplexing human inborn error of metabolism, Lesch-Nyhan disease. In Lesch-Nyhan disease, deficiency of HGPRT (hypoxanthine guanine phosphoribosyltransferase) as a result of a single structural gene mutation leads to complex behavioural pathology, with compulsive aggressiveness, and neurological abnormalities. HGPRT alleles with varying residual enzyme activity could be used to generate a graded series of HGPRT deficiencies for neurochemical and behavioural correlations and it is likely that a whole array of specific mutant mice will be constructed in the years ahead.

A. Peterson (McGill University, Montreal) described allophenic mosaic mice (strains C57BL and 129) constructed to test whether muscular dystrophy (*dy/dy*) in the mouse is of primary muscle or primary neurogenic origin. Mosaics between strains 129 and C57BL were observed to have muscle entirely of 129 origin (according to marker enzymes), while the rest of the animal is mosaic. Thus, Peterson could construct mosaic mice with *dy/dy* muscle; such genotypically abnormal muscle proved to be entirely normal on examination, indicating an extramuscular mechanism. If the complementary mice with genotypically normal muscle in a *dy/dy* C57BL × +/+ 129 mosaic develop the typical dystrophy, non-myogenic origins of the disorder will be proved. This genetic innovation may resolve a long-standing controversy in neurobiology.

Animal mutants continue to provide valuable insights for developmental neurobiology. A dysmyelinating mutant, for example, the *shiverer* mouse, lacks immunochemically detectable myelin basic protein, according to N. Baumann (Salpetrière, Paris) and A. Tsukada (Keio University, Tokyo). The compaction of lamellae is abnormal, but myelin is assembled despite the absence of basic protein, and the animal survives. A whole series of dysmyelinating mutants affecting central and/or peripheral myelination is now under comparative neurochemical investigation.

Invertebrates, especially nematodes (*C. elegans*) and *Drosophila*, are well-suited for genetic studies of certain limited kinds of behaviour. However, despite extensive anatomical and genetic analyses, neurochemical findings are negligible in nematodes and are only just emerging in *Drosophila*. Y. Dudai (Weizmann Institute, Rehovoth, Israel) described current studies of the *Drosophila* learning mutant '*dunce*', which appears to lack one isoenzyme of cyclic AMP phosphodiesterase. The gene for this enzyme maps on the X chromosome to exactly the same position as the *dunce* mutation. Knowledge of the chromosome map and availability of deletion mutants made possible this correlation. Direct assays (D. Byars, CalTech) indicate raised cyclic AMP concentrations in these flies. Obviously, there is still a gap between finding a phosphodiesterase deficiency and explaining the defect in learning olfactory differences.

Human mutations have long fertilised neurochemistry, with Tay-Sachs disease as the classic example. Gangliosides were discovered in brain tissue from patients with Tay-Sachs disease (TSD), who accumulate large amounts. The sequential nature of normal degradation of sphingolipids was revealed by recognition and analysis of a whole series of human lipid storage diseases, each due to a single gene mutation and resultant enzyme deficiency.

K. Sandhoff (University of Bonn) demonstrated anew that studies of these mutations can advance basic biochemistry of the brain. He described an endogenous activator protein essential to the physiological action of hexosaminidase A (deficient in TSD) on lipid soluble substrates in micelles *in vitro*. Presumably, this activator is crucial for Hex A action on lipids within membranes *in vivo*. In clinical neurochemistry, the activator protein

*Symposium on Genetic Approaches to Neurobiology and Neurological Disorders, University of Patras School of Medicine, Patras, Greece, 30-31 August, 1979; official satellite Symposium of Congress of International Society for Neurochemistry, Jerusalem, 2-6 September, 1979. Organisers were S. Doxiadis, P. Kafatos, E. Kouvelas, A. Simopoulos, J. P. Blass and G. S. Omenn.

G. S. Omenn is Associate Director, Office of Science and Technology Policy, Washington, DC and J. P. Blass is Professor of Neurology, Cornell University, New York.

0028-0836/79/410429-02$01.00

effect can explain the previously perplexing patterns of accumulation of gangliosides and globosides in patients with the various forms of TSD; Hex A, but not Hex B, is strikingly activated. Finally, three TSD patients with apparently normal Hex A activity (AB variant) were found to lack the Hex A-activator protein. It is very likely that analogous activator proteins specific for sulphatides and other lipids exist. They may prove to have interesting protein structures, and a sulphatide-specific activator protein may account for known cases of metachromatic leukodystrophy (MLD) with apparently normal activity of the arylsulphatases.

These highlights illustrate the power and sensitivity of genetic approaches to studies of complex functions of the nervous system and behaviour.

As this Symposium was an integral part of the Jerusalem meeting of the ISN, it is significant to note that Professor Ekram Abdel Salam of Cairo University and Professor Yadin Dudai of the Weizmann Institute were both active participants. In the near future, we expect that such contacts will be made directly in Egypt and in Israel. ☐

Interstellar molecules

from B. Zuckerman

AFTER a decade of explosive growth, the study of interstellar molecules has reached a certain level of maturity. That seemed to be the picture that emerged from a recent symposium at which the organisers rather successfully blended a combination of astronomers, physicists, chemists and spectroscopists. That they were perhaps not entirely successful was suggested during the presentation of one European astronomer, when a "thank you" from the speaker directed to the slide projectionist woke up a sizable fraction of the audience who then proceeded to deliver an unexpected round of applause.

The startling new results that characterised the early 1970s were absent from this symposium. Still there are many controversies and mysteries yet to be unravelled. In spite of the very low temperatures and fairly quiescent states that characterise most interstellar molecular clouds there is evidence of surprisingly energetic phenomena hidden deep inside some clouds. S. Beckwith (Cornell University), T. Geballe (California Institute of Technology), N. Scoville (University of Massachusetts, Amherst) and D. Hollenbach (NASA Ames Research Center) discussed high velocity gas and shock waves in the cloud behind the Orion Nebula. The very large energies associated with the high velocity gas imply the existence of massive stellar winds or an explosive event (perhaps a supernova) inside this molecular cloud.

Even for the more typical molecular cloud, J. Silk (University of California, Berkeley) and C. Norman (University of Leiden) suggested that support against gravitational collapse can best be provided by energetic winds from new stars similar to the Sun that have just formed inside the clouds. That molecular clouds are somehow stabilised against free-fall gravitational collapse now seems generally, although perhaps not universally, accepted. Indeed the present controversy rages around the question of whether the giant molecular cloud complexes 'live' for at least a few times 10^8 years (P. Solomon, State University of New York, Stony Brook) or 'only' a few times 10^7 years (L. Blitz, University of California, Berkeley). In the former case the molecular clouds are well distributed throughout the inner disk of our Milky Way Galaxy, in the latter case they are confined to the spiral arms. Future observations of carbon monoxide in external galaxies should resolve the matter.

A renaissance in this field awaits development of sensitive new receivers especially for wavelengths $\leqslant 1$ mm to be used with large new mm wavelength telescopes and interferometers presently under construction or envisaged. Previews of some of the exciting results to be expected at high frequencies were given by P. Vanden Bout (University of Texas) and by T. Phillips (Bell Telephone Laboratories). Phillips reported submillimetre observations of CO (at 461 GHz) and of H_2O (at 380 GHz) obtained from NASA's Kuiper Airborn Observatory.

One of the fundamental limits in this field is the total number of different interstellar molecules that may eventually be found by radioastronomers. P. Thaddeus (Goddard Institute for Space Studies, New York) pointed out that 52 interstellar molecules have now been identified but, from considerations of the limits set by confusion due to overlapping weak lines from various molecules, he estimated that probably only about three times this number would ever be identified. Even so, the microwave spectroscopists will have their work cut out for them if we are to assign the observed transitions properly. ☐

---

*The Symposium on Interstellar Molecules was held at Mont Tremblant, Quebec on 6-10 August and sponsored by the International Astronomical Union in conjunction with the Herzberg Institute of Astrophysics and the National Research Council of Canada.

B. Zuckerman is Professor of Astronomy in the Astronomy Program, University of Maryland.

The end of the Cretaceous

from A. Hallam

IT is widely recognised that the end of the Cretaceous witnessed one of the most significant mass extinction events in Earth's history, both on land and at sea. Whereas certain groups like the ammonites had been in decline for some time, others such as the dinosaurs and planktonic foraminifers were still flourishing until the end of the period. The many hypotheses that have been proposed to account for this striking extinction event fall into two categories, respectively invoking extraterrestrial and terrestrial causes.

The extra-terrestrial or 'astronomical' hypotheses involve increased levels of some form of unpleasant radiation from outer space, perhaps at times of geomagnetic reversals. They have been strongly criticised and are not widely accepted today but the general notion cannot yet be decisively discounted and has been recently revived by Reid *et al.* (*Nature* **259**, 177; 1976; **275**, 489; 1978), who suggest increased ultraviolet radiation at the Earth's surface as a result of breakdown of the protective ozone belt, caused by increased solar proton flux or supernova explosions. One of the strongest arguments against such radiation events to account for various mass extinctions in the past is that terrestrial floras were comparatively unaffected. It is noteworthy therefore that Krassilov (*Palaeontology* **21**, 893; 1978) has recorded an abrupt change in terrestrial floras across the Cretaceous-Tertiary boundary.

The 'terrestrial' group of hypotheses usually postulate some form of sea level and/or climatic change. There is good stratigraphic evidence of a major eustatic regression at the end of the Cretaceous, and such regressions plausibly account for a number of mass extinction episodes of shelf faunas in the Phanerozoic, but it is not so evident why planktonic and terrestrial groups should be seriously affected. One ingenious solution to this problem was proposed some years ago by Tappan (*Palaeogeog., Palaeoclimatol., Palaeoecol.* **4**, 187; 1968). She postulated that the production of marine phytoplankton controlled the oxygen and carbon dioxide levels of the atmosphere through time, and that changes in relative and absolute abundance of these organisms had extensive effects on contemporary biota. Following the major late Cretaceous transgression which preceded the end Cretaceous regression, the influx of nutrient supply from land dropped as continents were reduced to base level. This and other associated processes led to a marked reduction in marine phytoplankton and a consequential

increase of atmospheric carbon dioxide and decrease of oxygen (due to reduced photosynthesis). These atmospheric changes were too much for the dinosaurs to cope with, though estivators and hibernators such as the crocodiles and turtles were able to survive into the Tertiary.

Data from new fields of research have now been brought to bear on the problem. Geomagnetic reversals as recorded in sedimentary sequences both on land and under the ocean can be used to add precision to stratigraphic correlation based on fossils. A biostratigraphically complete sequence of Upper Cretaceous and Palaeogene pelagic limestones at Gubbio, Italy has produced a record of geomagnetic reversals that closely matches the marine magnetic anomaly sequence (Alvarez *et al.*, *Bull. geol. Soc. Am.* **88**, 367; 1977). A detailed analysis of sedimentation rates at Gubbio suggests that the Maastrichtian — Danian faunal overturn might have happened very rapidly, of the order of 10,000 years or less (Kent *Geology* **7**, 66; 1979). Palaeontological work on a comparably complete sequence of pelagic deposits at Zumaya, Spain suggests that environmental stresses were first felt by planktonic foraminifera about 10,000 years before the end of the Maastrichtian, following which occurred the major crisis involving extinction of globotruncanid foraminifera and a drastic change in the nannoplankton flora (Percival & Fischer *Evol. Theory* **2**, 1; 1977).

Interest naturally focuses on whether or not the dinosaur extinction was coincident in time with that of the planktonic groups. Only if it was precisely coincident can the case for a drastic extra-terrestrial event seriously be upheld. Butler *et al.* (*Nature* **267**, 318, 1977) undertook a magnetostratigraphic study of a sequence of terrestrial sediments in New Mexico which they argued exhibited an unbroken transition across the Cretaceous — Tertiary boundary. By correlating with the Gubbio sequence they inferred that the dinosaurs became extinct slightly later than the planktonic foraminifera, perhaps by as much as half a million years. This correlation has been criticised by Alvarez *et al.* (*Geology* **7**, 66; 1979) who suggest that an unconformity might be present in the New Mexico sequence. If so, the marine and terrestrial extinction events could indeed be synchronous. Further information on the issue has recently been published by Lerbekmo *et al.* (*Nature* **279**, 26; 1979) in another magnetostratigraphic study of a terrestrial sequence in Alberta. Their data indicate an approximate synchroneity of dinosaur and foram extinctions just below anomaly 29, the maximum error being about 100,000 years.

Oxygen isotope data from foraminifera in deep sea cores has been used to monitor water temperature changes across the Cretaceous — Tertiary boundary. McLean (*Science* **201**, 401; 1978) cited isotope work on benthic forams indicating a late Maastrichtian warming event and went on to propose a novel interpretation of dinosaur extinctions by a temperature rise rather than a temperature fall, as had been frequently speculated previously. He failed, however, to cite other isotope work indicating just the reverse, a slight cooling through Maastrichtian time (Savin & Douglas *Bull. geol. Soc. Am.* **84**, 2327; 1973; Saito & Van Donk *Micropalaeontology* **20**, 152; 1974). This latter interpretation is indeed more in accord with what is known from the terrestrial plant record (for example Krassilov *Palaeogeog., Palaeoclimatol., Palaeoecol.* **17**, 157; 1975).

The most recent isotope data is reported from an exceptionally well documented Atlantic core by Thierstein and Berger (*Nature* **276**, 461; 1978). The oxygen isotope values remain more or less stable through the Maastrichtian part of the core and then exhibit a sharp change into the basal Danian. This can be interpreted as signifying a sudden water temperature increase (in which case it comes too late to support McLean) or as a salinity decrease. Thierstein and Berger favour the latter interpretation and cite the evidence as support for their hypothesis that the extinction event was caused by a large-scale invasion of the ocean by low salinity water from a previously isolated high latitude basin. Their completely original idea on mass extinctions is likely to prove as controversial as many others on this subject, especially as the existence of extensive high latitude ice masses at the end of the Cretaceous seems unlikely for a number of reasons, and it is hard to see how otherwise the requisite large volume of low salinity water could be created. Despite all the new data and ideas it seems probable that the extinctions at the end of the Cretaceous will continue to intrigue us for some time to come. ☐

SEASAT's short-lived mission

from T. D. Allan

On 10 October, 1978, after little more than one hundred days of operation, the transmissions from SEASAT-1 — the first satellite dedicated to a study of the ocean surface — were brought to an untimely end by a catastrophic short circuit in the power system.

The declared first objective of SEASAT's mission was to test whether satellite microwave sensors could provide data of a high enough accuracy to be incorporated into existing systems for forecasting and charting global ocean conditions. It was an ambitious project which had been planned for over 10 years by oceanographers and NASA engineers. The accuracy criteria laid down as design goals for the satellite sensors fell little short of the accuracies that can presently be achieved by ships and surface buoys. If SEASAT's sensors can be shown to have achieved these precisions under different ocean conditions then routine monitoring of the sea surface from satellites becomes a real and exciting alternative to the sparse data of variable quality currently obtainable from surface vessels.

The major difference in SEASAT's payload from previous environmental satellites was the concentration of radar sensors with the all-weather capability that is essential for repetitive surveys of sea areas mostly covered by cloud. Of the four microwave sensors carried on SEASAT — three active and one passive — the radar altimeter had some space heritage, previous versions having been flown on Skylab and GEOS-3. However, no instrument had even measured its own orbiting height to an accuracy of ± 10 cm which was the precision required to provide useful information on ocean currents, tides and surface waves.

The radar scatterometer was designed to satisfy the weather forecasters' requirements for a comparatively dense grid of wind field observations. The instrument swept out swathes of over 500 km on either side of the spacecraft's sub-orbital track and related ocean backscatter to surface winds. Further information on wind speed was provided by the passive microwave radiometer which measured brightness temperature at five frequencies in the range 6.6 — 37 GHz.

The most controversial of SEASAT's suite of sensors was the synthetic aperture radar (SAR) which, operating at 1.3 GHz (23 cm wavelength), was designed to produce an image of the sea surface with a spatial resolution of 25 m. The data rate required to achieve such a fine resolution is so high (approximately 100 megabits s^{-1}) that on-board recording was out of the question and SAR could only be operated in real time over areas within range of a ground receiving station. The European SAR station was at Oakhanger in Hampshire, operated by the Royal Aircraft

Establishment (Farnborough) under an agreement between ESA and NASA.

The performance of a satellite's sensors must be assessed against reliable surface observations and the question now being asked of the SEASAT mission is whether sufficiently diverse surface data were obtained last summer to satisfy the main 'proof-of-concept' objective. A special data-gathering cruise was organised by the US National Oceanographic and Atmospheric Administration (NOAA) in the Gulf of Alaska during a 4-week period in August-September 1978. Observations of wind, waves, temperature and other parameters were made by two ships, four aircraft and an array of surface buoys. A detailed comparison between these observations and the signals from SEASAT's sensors was made recently during two workshops held at the Jet Propulsion Laboratory, Pasadena. More than 60 scientists and engineers from several oceanographic and space research centres were involved and the preliminary results for each sensor have been reported in *Science* (**204**, 1405-1424; 1979).

The scatterometer task group had evolved three candidate algorithms which made slightly different assumptions in relating the measured scattering coefficient to the wind vector as a function of incidence angle, azimuth angle and polarisation. Since these were largely constructed from a limited set of aircraft measurements it is not surprising that the satellite models required some modifications especially with regard to determining wind direction unambiguously. An analysis of some 30 comparisons showed the scatterometer winds to be biased high by 1.9 m s^{-1} with a standard deviation about this bias of 1.8 m s^{-1}. When the scatterometer values were compared with wind fields produced by kinematic analysis techniques (as opposed to spot measurements) wind speed differences were in the range 1.1–5.2 m s^{-1} (scatterometer higher) and for direction the means were less than 10° with standard deviations of approximately 20°. Wind speeds were generally low throughout the experiment and part of the observed differences may be attributed to errors in the surface spot observations.

The scanning microwave multi-channel radiometer (SMMR) measured Earth's radiation at five microwave frequencies at both vertical and horizontal polarisation. The algorithms to extract sea surface temperature and wind speed are correspondingly complex since they involve ten values of brightness temperature with different weightings according to frequency, to the antenna pattern, and to the amount of cloud and rain present. Over open ocean the best wind speed determinations gave a standard deviation of 3 m s^{-1} about a bias of 1.5 m s^{-1}. Sea surface temperature estimates were disappointing with a standard deviation of 1.5 °C about a bias of 3-5 °C. However, further analysis may determine the cause of the bias and suitable correction can be made. The SST value is averaged over a footprint approximately 120 km on the side.

In validating the performance of the radar altimeter the GOASEX data were used to calibrate only significant wave height and radar backscatter; the calibration of the altimeter's height determination was made over a range in Bermuda. During its last few weeks of operation SEASAT was manoeuvred into a frozen orbit pattern which allowed it to pass over Bermuda every 3 days. The calibration range included high precision tide gauges and a laser tracking system. For four overhead passes where laser tracking was possible the weighted mean bias in the altimeter-derived height was -50 ± 11 cm (over a height of 800 km). During the engineering assessment of the altimeter the noise in the height measurements for a 4-m significant wave height was 5-8 cm. If relative changes of this order can be detected in sea surface topography than valuable information can be obtained on ocean circulation patterns, eddies, tides, and the marine geoid. For this reason, the altimeter represents perhaps the greatest loss to the oceanographic community.

There was some lively discussion before the synthetic aperture radar was flown on SEASAT as to its ability to image surface waves. SAR sweeps out a 100 km swathe centred about a point 250 km to the right of the satellite's sub-orbital point. Each target remains in the radar beam for about 2 seconds and it was argued that in this time the movement of the shorter capillary waves which scatter the L-band energy could be more than enough to blur the return image. And since the detection of the larger gravity waves was seen to depend on their modulation of the shorter waves, it seemed doubtful if they could be detected. In the event, SAR produced several images of swell waves not only in the Gulf of Alaska but in other ocean areas including those covered by the Oakhanger station. Wave directions can be estimated to a few degrees and wave length greater than about 100 m appear to show clearly, given a certain minimum significant wave height (apparently around 2 m), certain minimum wind conditions and, up to the present, a wave direction predominantly across the satellite track. Apart from imagery of surface swell the SAR record analysed to date has shown remarkable examples of internal wave trains, surface pollutants, ice features in the Arctic, and details of shallow sand banks in the Channel and other shallow water areas around the UK. Its fine resolution (25 m against Landsat's 80 m) and its independence from adverse weather conditions have now aroused the interest of land surveyors and geologists.

Before the launch of the spacecraft the SEASAT Users Research Group of Europe (SURGE) had submitted a list of proposed experiments to NASA and as a result SAR was activated over a number of European sites. The most important of these was JASIN — a Joint Air-Sea Interaction experiment in a comparatively small area close to Rockall in which up to 14 research vessels, 3 aircraft and 35 buoys took measurements in the period mid-July to mid-September. Although SEASAT's early demise is proving inceasingly regrettable as its results become available, it was a piece of extremely good fortune that one of the most intensive research programmes of sea-surface observations took place during its short life. Now that the sensor algorithms have been refined and modified following GOASEX, the JASIN data should allow a comprehensive assessment of the performance of each microwave sensor. It may still be possible to go a long way towards reaching SEASAT's first objective — to prove the concept of reliable remote sensing of the seas from satellites. □

100 years ago

It may interest our readers to know the elevations which at present are reached by lines of railway in different parts of the world. The Apennine Railway reaches its highest point at an elevation of 617 metres above sea-level; the Black Forest Railway ascends to 850 metres, the Semmering line to 890, the Caucasus line to 975 metres. The St. Gothard tunnel is 1,154 metres above sea-level; the railway across the Brenner reaches 1,367 metres; the Mont Cenis Railway ascends to 1,338 metres, the North-Pacific line to 1,652, the Central-Pacific to 2,140, and the Union-Pacific to 2,513 metres. The highest of all is the line across the Andes, which reaches an elevation of 4,769 metres.

We have on our table the following works: — "The Spiders of Dorset," Rev. O. Pickard Cambridge; "Chemical and Geological Essays," by T. Sterry Hunt (Trübner); "Deaths in Childbed," Dr. Æneas Munro (Smith, Elder, and Co.); "The Silk Goods of America," W.C. Wyckoff; "Structural Botany," Dr. Asa Gray (Trübner); "Luxurious Bathing," A. review article

Incommensurable structures

R. Pynn

Institut Laue-Langevin, 156X Centre de Tri, 38042 Grenoble Cedex France

The discovery of incommensurably distorted structures has important implications for the study of structural phase transitions.

ON 8 June, 1912 von Laue and coworkers presented a paper entitled *Interferenz-Erscheinungen bei Roentgenstrahlen* in which a theory of the diffraction of X rays by a periodic lattice of atoms was outlined[1]. In 1913, Bragg[2] reported the structures of four alkali halides determined by X-ray techniques. Since these early experiments many thousands of crystal structures have been determined and the concepts of crystal periodicity and symmetry have had a central role in the development of solid state physics. According to the conventional view crystalline solids are composed of plane-sided cells which are stacked on a regular lattice of sites. Depending on the symmetry of the lattice and of the arrangement of the atoms within each cell, a crystal is assigned to one of the 230 possible space-symmetry groups. By definition, when any of the symmetry elements which comprise the space group are applied to the crystal it is mapped into itself and its physical properties are unchanged. Apart from some pathological and (as we shall see) interesting exceptions the symmetry groups encountered in practice comprise rotations, reflections and translations in our three-dimensional world. Nevertheless, it is simpler, and more relevant to this article, to consider a one-dimensional crystal (chain) such as that depicted in Fig. 1*A*. Evidently, left–right translation of the chain by any multiple of the unit-cell side, *a*, leaves the chain unaltered, as does inversion (reflection) through a suitably chosen point.

Structural transformations

Many solid materials have been found to change their crystal structure when some externally applied perturbation such as temperature is varied. Structural transitions of this type, particularly those which occur continuously, have been the subject of intensive study during the past 20 years or so[3]. One type of continuous transition of the so-called displacive type, can be visualised with the aid of Fig. 1. Suppose that the atoms of the chain are subjected to longitudinal (left–right) displacements whose amplitudes vary sinusoidally in space as shown in Fig. 1*B*. The atomic positions which result from this modulation will be as depicted in Fig. 1*C*. A transition between the distorted chain and the high-symmetry uniform chain occurs when the modulation amplitude vanishes. This amplitude is thus the order parameter of the transition and plays an analogous role, for example, to the magnetisation in a transition between ferromagnetic and paramagnetic states. The fact that the modulation vanishes continuously at the transition temperature, T_c, gives rise to the designation 'continuous transition'.

Much of the detailed information which has been obtained about real structural transformations has been derived from diffraction experiments with X rays or neutrons[4]. Once again, these experiments may be understood with the aid of a one-dimensional example. Suppose that a beam of X rays of wave vector $\mathbf{k}_0$ (wavelength $\lambda_0 = 2\pi/k_0$) impinges on the one-dimensional chain depicted in Fig. 2*A*. Each atom of the chain acts as a scattering centre and radiates X rays of wave vector $\mathbf{k}$ where $|\mathbf{k}| = |\mathbf{k}_0|$. The interference between the various scattered beams will be constructive only if the component of $\mathbf{k}_0 - \mathbf{k}$ in the *y*-direction is a multiple of $2\pi/a$. Generally, the quantity $\mathbf{k}_0 - \mathbf{k}$ is known as the scattering vector and is denoted by $\mathbf{Q}$. In the reciprocal space defined by the cartesian components of $\mathbf{Q}$, diffraction from the one-dimensional chain occurs only for $Q_y = 2\pi n/a$ where n is an integer. The values of $\mathbf{Q}$-components (Q_x, Q_z) perpendicular to the chain are immaterial. Thus the loci of allowed scattering vectors comprise a series of sheets in reciprocal space, as shown in Fig. 2*B*. These arguments may be easily extended to both two- and three-dimensional scattering arrays. A two-dimensional array (Fig. 2*C*) may be regarded as a chain (in the *x*-direction) of chains (in the *y*-direction). Its diffraction pattern is therefore characterised by the intersections of two mutually perpendicular sets of planes in reciprocal space. As shown in Fig. 2*D*, this gives rise to rods of scattered intensity. Extending the argument to one more dimension one finds that the diffraction pattern of a three-dimensional crystal is a three-dimensional array of points in reciprocal space. While such an array of Bragg points is the most commonly observed form of diffraction, patterns similar to those depicted in Fig. 2 are not simply figments of the imagination, but can (as will be shown) be observed in the laboratory.

As we have seen, the diffraction pattern of the uniform chain in Fig. 1*A* consists of a series of sheets in reciprocal space separated by multiples of $2\pi/a$. The diffraction pattern of the modulated chain (Fig. 1*C*) may be deduced in an analogous manner. As a result of the choice of the modulation wavelength as $4a$, every fourth atom is displaced by the same amount. The distorted structure can thus be described in terms of a unit cell which is four times larger and contains four times as many atoms as the original one. Accordingly, the diffraction pattern of the distorted phase consists of sheets separated by $\pi/2a$ rather than by $2\pi/a$. That is, three equally spaced sheets are inserted between each pair shown in Fig. 2*B*. Evidently, the intermediate sheets, known as satellite reflections, disappear when the amplitude of the lattice modulation tends to zero. (When all sheets are equally spaced, the intermediate ones are generally known as superlattice reflections. The term 'satellite reflection' is used here to avoid a proliferation of terminology.) Thus, the intensities of the satellite reflections serve as a measure of the modulation amplitude, that is, of the order parameter of the transition.

The previous example is a prototype for most of the continuous structural transitions which have been studied by diffraction

techniques during the past 15 years or so. In general, the modulations which have been observed apply to a three-dimensional crystal and the diffraction patterns consist of a lattice of points rather than sheets in reciprocal space. Nevertheless, the distinction between main Bragg points and satellite reflections remains the same. The canonical example[5] of this type of phase transition is that which occurs at 105 K in $SrTiO_3$. Above the transition temperature the crystal structure, shown in Fig. 3*B*, consists of Ti atoms at the corners of a cubic cell surrounding a Sr atom at the centre of the cell. Each Ti is surrounded by oxygen atoms located at the apeces of the octahedra drawn in Fig. 3*B*. In the low-temperature (distorted) phase the oxygen octahedra, which are linked by a common oxygen atom at their corners, are rotated in the senses indicated by the arrows. This cog-wheel type of rotation is shown more clearly in Fig. 3*A*, where the positions of the oxygen atoms at low temperature are indicated by circles while their positions above the transition are indicated by hatched circles. Evidently, the low temperature distortion is periodic but the modulated variable is the angle of rotation of the octahedra rather than the longitudinal atomic displacement of Fig. 1. The periodicity of the modulation (see Fig. 3) is, however, enough to cause a doubling of each unit-cell side.

Most previous reports on structural transitions described systems in which the unit-cell size either remained the same or was changed by a simple multiple at the transition. However, it is certainly not *a priori* necessary for a lattice modulation to have a periodicity which is a rational multiple of a unit-cell side. An example of a modulation which does not satisfy this simple criterion and which is thus incommensurable with the undistorted lattice is shown in Fig. 1*D*. (The term incommensurate has been used in this context, probably without malice. Incommensurate is defined as not adequate.) The atomic arrangement in the incommensurable phase is depicted in Fig. 1*E*. This phase has the remarkable property that no two atoms are displaced by the same distance from their positions in the undistorted phase. It is thus impossible to find any lattice translation which maps the crystal into itself. For the case of a three-dimensional crystal this means that the crystal does not belong to any of the 230 space groups mentioned earlier. In spite of this apparent lack of symmetry, the diffraction pattern of an incommensurably modulated structure is relatively simple. Just as for a commensurable distortion there are principal reflections, separated by $2\pi/a$, and satellites, whose positions depend on the wave vector q_0 of the modulation ($q_0 = 2\pi/1.705a$ for Fig. 1*D*, *E*). The satellites are separated from the principal reflections by multiples of q_0.

Symmetry classifications of incommensurably modulated structures have been developed[6]. The distorted chain in Fig. 1*E* is mapped into itself by an operation which translates the chain to the right by a distance na and changes the phase of the modulation by q_0na. Thus, the translational-symmetry group of the crystal consists of operations which translate the crystal and, at the same time, slide the distortion wave with respect to the crystal. This means that the symmetry operations act in a hyperspace whose dimensionality is greater than that of the crystal. For a three-dimensional crystal with a single modulation wave, this hyperspace is four-dimensional and comprises the three spatial dimensions and a dimension which refers to the phase of the modulation.

Incommensurable phase transitions

The first structurally incommensurable phase transition[7] to be identified as such was found in the insulator $NaNO_2$. Subsequently, such transitions have been discovered both in metallic and insulating materials. The physical effects which drive the transitions are somewhat different in the two cases. For the insulators it is often found that competing, short-range interatomic forces of different ranges and similar magnitudes give rise to an incommensurably modulated phase. To see crudely how this may arise, consider the monoatomic chain in Fig. 1 and suppose that only elastic forces between first and second neighbour atoms contribute to the energy. The latter may then be written as

$$U = \sum_{n=1}^{N} \left\{ A_1 \sum_{i=\pm 1} (u_n - u_{n+i})^2 + A_2 \sum_{j=\pm 2} (u_n - u_{n+i})^2 \right\} \quad (1)$$

where u_n is the longitudinal displacement of the nth atom from its lattice site and A_1 and A_2 are the first and second neighbour harmonic force constants, respectively.

Expanding the displacements as a Fourier series

$$u_n = \sum_q u_q \cos qna \quad (2)$$

and substituting in equation (1) one finds that the energy is given by

$$\begin{aligned} U &= 4 \sum_q u_q^2 [A_1(1 - \cos qa) + A_2(1 - \cos 2qa)] \quad (3) \\ &= 4 \sum_q u_q^2 A_q \end{aligned}$$

A sinusoidally modulated structure will be stable if A_q in equation (3) has a minimum value for a non-zero wave vector q_0. Necessary conditions for this to occur are that

$$\frac{\partial A_q}{\partial q} = 0; \quad \frac{\partial^2 A_q}{\partial q^2} > 0 \quad (4)$$

at the wave vector q_0. These conditions imply that a modulation of wave vector q_0 given by

$$\cos q_0 a = -A_1/4A_2 \quad (5)$$

will be stable provided $A_1 < 4|A_2|$ and $A_2 \leq 0$.

A well-studied system which exemplifies the above calculation is the insulator K_2SeO_4. In this material[8], which transforms to an incommensurable phase at 130 K, force constants (see A_1 and A_2 above) between first- and second-neighbour layers of atoms decrease strongly with decreasing temperature above 130 K. However, third-neighbour interlayer forces increase slightly in the same temperature interval. It is thought that the competition between these short-range forces is responsible for the observed transition.

For conducting materials, interesting incommensurable transitions result from the interaction between conduction electrons and the atomic lattice. These interactions give rise to effective interatomic forces which are long-range. Although the appearance of an incommensurable phase could be described in terms of competition between such forces, this language is unusual for metals. Rather, attention is focused on the fact that in certain cases the energy of a metal is lowered if the conduction-electron density is spatially modulated[9,10]. Thus, a so-called charge density wave (CDW), whose wave vector is an extremal Fermi surface dimension, is set up in the conduction electron gas. The ions of the lattice respond to the CDW, in an attempt to preserve local charge neutrality, and an incommensurable lattice modulation is thereby generated. Examples of this phenomenon are to be found among the transition metal dichalcogenides[11], the one-dimensional charge-transfer salts (such as TTF–TCNQ[12]) and certain chain compounds (for example KCP[13]). The transition to the incommensurable phase is known as a Peierls transition.

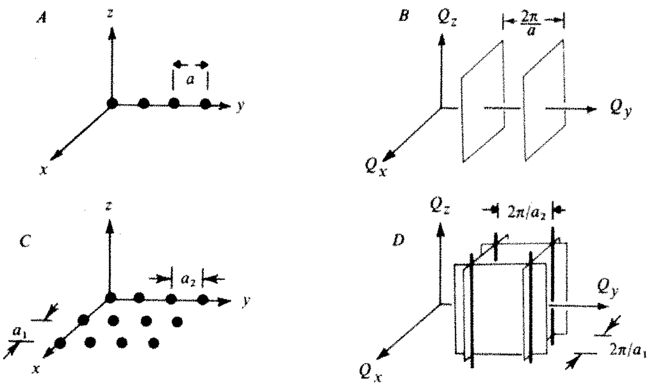
Anharmonic effects

Although instructive, the calculation leading to equation (5) is deficient in several ways. First, equation (1) is a truncated expansion of the total energy in terms of the displacements u_n. There ought to be terms of higher order in u_n. These so-called anharmonic terms limit the magnitude of the amplitude of the incommensurable distortion which, according to equation (3), is otherwise unbounded. A second defect of equation (1) is that it is a zero-temperature approximation. At finite temperatures, the addition of the obligatory entropy term may radically alter the behaviour deduced above, and may even suppress the distorted phase entirely.

In addition to restricting the amplitude of a modulation, the anharmonic terms mentioned above have an important qualitative effect on the nature of a modulated phase. In a commensurably modulated structure, such as Fig. 1*C*, the anharmonic terms determine the optimum phase of the distortion (Fig. 1*B*) with respect to the uniform lattice (Fig. 1*A*). For a particular choice of phase, such as that depicted in Fig. 1*A*, *B*, in which every other atom is undisplaced in the modulated phase, the energy is minimised. This situation is unique to commensurably modulated structures. In the incommensurable case, the phase of the distortion is, by definition, different at each lattice site. The energy of the system is thus unchanged if the modulation is translated with respect to the lattice and the concept of 'optimum phase' has no meaning. Nevertheless, in any small region, the incommensurable wave of Fig. 1*D* causes a distortion which is very similar to that of a commensurable modulation of wavelength $5a/3$. There are even regions in which the distortion has a phase which reduces the local contribution to the energy. However, these regions are compensated by others in which the distortion has the 'wrong' phase and the local energy is large. In this situation there are two ways in which the sinusoidal modulation may be modified in order to lower the energy of (render more stable) the distorted phase. First, the amplitude of the distortion may be increased in the 'correct'-phase regions and decreased in the 'wrong'-phase regions. Alternatively, the phase may be distorted and made to vary from region to region. It is generally accepted that the latter possibility occurs most readily. To calculate the effect[14] it is necessary to return to equation (2) and to replace the discrete atomic positions (na) by a continuous coordinate x. Equation (2) is then rewritten as

$$u(x) = A\cos(q_c x + \phi(x)) \tag{6}$$

where q_c is a commensurable wave vector close to the wave vector of the sinusoidal distortion deduced from equation (5). $\phi(x)$ is a phase whose variation with position, x, minimises the energy obtained when equation (6) is substituted in the anharmonic (non-truncated) version of equation (1). The equation which results from this minimisation procedure is known as the (static) Sine–Gordon equation[15]. This nonlinear differential equation has solutions similar to those represented by the stepped curve in Fig. 4. The straight line in this figure represents the phase variation which would correspond to the simple, sinusoidal modulation with a wave vector given by equation (5). Each step in the curve in Fig. 4 represents a sudden change of phase of the modulation. The steps can be regarded as walls separating domains in which $\phi(x)$ is independent of x and which are thus commensurably distorted. In these domains the 'optimum phase' argument applies and the anharmonic energy is thereby minimised. This reduction of energy of the system more than offsets the cost in harmonic energy which results because $\phi(x)$ does not follow the straight line in Fig. 4, but is stepped instead. Evidence for the importance of anharmonic effects and for the plausibility of the solution sketched in Fig. 4 have been obtained, for example, by Moncton *et al.*[16] in their neutron scattering experiments with 2H–TaSe$_2$.



Direct space Reciprocal space

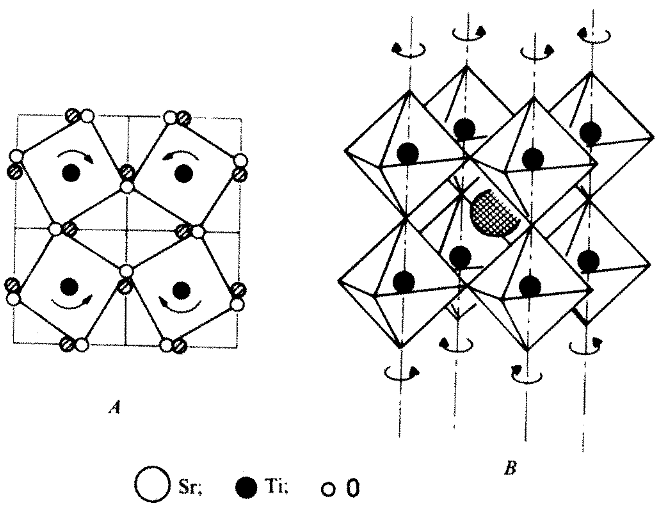

Fig. 3 *A*, A plan view of the structure of SrTiO$_3$ below the 105 K phase transition. The hatched circles represent the positions of the oxygen atoms in the high temperature (symmetric) phase. Arrows indicate the 'cog-wheel' type distortion induced by the transition. *B*, Three-dimensional representation of the symmetric phase of SrTiO$_3$.

The phase steps in Fig. 4 are called solitons. They are an example of the solitary waves or kinks which are the solutions to many nonlinear wave equations. As an aside, one may note that solitary waves are not a new phenomenon in physics. In 1844, Russell reported a solitary water wave which he had observed in a canal[17]: "... rolled forward with great velocity, assuming the form of a solitary elevation, a rounded, smooth and well-defined heap of water, which continued its course along the channel apparently without change of form or diminution of speed. I followed it on horseback ... and after a chase of one or two miles I lost it in the windings of the channel". The solitary wave pursued by Russell bears a singular resemblance to the derivative $d\phi/dx$ of the function plotted in Fig. 4 although, in fact,

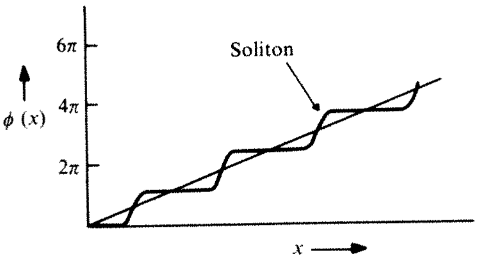

Fig. 4 Variation of the phase $\phi(x)$ (see equation (6)) in an incommensurably modulated structure.

the equations governing the two phenomena are not quite the same. (The relevant equation in this case is known as the Korteweg–de Vries equation.)

Figure 4 shows that the difference between a commensurably distorted phase and an incommensurably distorted one is that the latter contains a finite number of solitons. In many cases, it is found that the intersoliton spacing increases as the temperature of an incommensurably modulated phase is decreased. Finally, the number of solitons may become zero at a transition to a commensurably distorted structure. Such a transition, examples of which have been found in both metallic[12] and insulating systems[8], has become known as a lock-in transition. At the transition, the periodicity of the distortion 'locks in' to that of the underlying lattice.

Fluctuations

The picture presented so far of an incommensurably distorted structure has been a static one. Nevertheless, at finite temperatures there will be fluctuations of atomic positions about their mean values. As always, these fluctuations can be Fourier analysed in both space and time and each Fourier component represents a normal mode or phonon. In view of the somewhat tangled atomic arrangement which is to be expected in the domain walls (solitons) this Fourier analysis probably involves many coupled terms. It may therefore be more profitable to think about possible fluctuations of the distortion wave (see equation (6)) itself. Two fluctuation modes suggest themselves: phase fluctuations (variations of ϕ with space and time), and amplitude fluctuations (variations of A). The first were originally discussed by Overhauser[18] who suggested the name phason for these modes which consist, in fact, of fluctuations in the positions of the solitons. With lack of originality I (and perhaps others?) adopted the name amplitudon for the second type of mode. Not surprisingly, the ability to name these modes has not greatly accelerated their discovery and, at the time of writing, there has been no unambiguous identification of a phason made in an incommensurably modulated phase.

Phasons have been found[19], however, in the unusual chain compound $Hg_{3-\delta}AsF_6$. In this material, linear chains of mercury cations are imbedded in a tetragonal matrix of AsF_6^- anions. The inter-mercury spacing is incommensurable with the lattice constant of the matrix and the (long wavelength) phasons consist of rigid motion of the chains with respect to the matrix. At sufficiently high temperatures (above 120 K) the mercury chains are uncorrelated and, in a neutron diffraction experiment, produce sheets of scattered intensity similar to those in Fig. 2*B*. Phasons are observed around these diffuse sheets.

Surfaces

In the above discussion, the word incommensurable referred to the relationship between the periodicities of a basic structure and of the modulation which distorts it. However, the word is also used in a slightly different context, which is well exemplified by the case of a rare gas monolayer on a crystalline substrate. A one-dimensional representation of this system is displayed in Fig. 5. The period which the lattice of gas atoms would adopt in the absence of the substrate is not the same as the period of substrate atoms. The two periodicities are incommensurable. Since the substrate lattice is fairly rigid the interaction between the substrate and the adsorbed gas atoms tends to modulate the positions of the latter. That is, the substrate tries to impose its periodicity on the adsorbate. The adsorbate is thus analogous to the atomic chain in Fig. 1*A*, and the substrate is a manifestation of the abstract 'imposed modulation' which was described earlier and which is depicted in Fig. 1*D*. In view of the similarity between the substrate–adsorbate problem and the modulated-lattice problem, it is not surprising that many features of the solutions of these problems resemble one another. Neutron diffraction studies have been carried out, for example, on a monolayer of argon adsorbed on the surface of graphite[20]. Since the diffraction pattern of the layer is a set of rods in reciprocal space (Fig. 2*C*, *D*), while that of the substrate comprises the familiar Bragg points, the sources of diffraction are distinguishable. In the argon–graphite system the adsorbate periodicity at low temperatures is incommensurable with that of the substrate. In such incommensurable layers a soliton (or domain wall) structure, similar to that discussed for the linear chain, and sketched in Fig. 5, is expected[21,22]. Transitions between commensurable and incommensurable monolayers have been studied by electron diffraction techniques by Fain[23,24], Venables[25] and their coworkers.

A phenomenon which occurs in adsorbate–substrate systems and which is related to incommensurability is orientational epitaxy[26,27]. This uninformative phrase applies to a situation in which the crystallographic (symmetry) axes of an incommensurable adsorbate are rotated slightly with respect to the axes of the substrate. Examples of this effect are found with silver adsorbed on mica[28] and with some rare gases (notably Ar[29]) adsorbed on graphite. The effect arises because the interaction energy of the substrate and the (incommensurable) adsorbate depends on the forces, represented by springs in Fig. 5, between the adsorbate atoms. Less energy is needed to produce a shear distortion of the adsorbate than is needed for a compression or contraction of similar magnitude. Thus, the shear is favoured and the adsorbate is rotated with respect to the substrate.

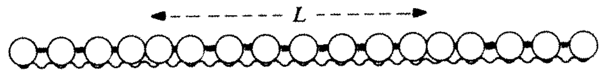

Fig. 5 Artist's view of interacting gas atoms adsorbed on the surface of a crystalline substrate. Two domain walls separated by a distance *L* are depicted. Between the walls, the gas atoms are in registry with the substrate.

Conclusions

I have attempted to review simply some of the underlying ideas involved in the study of incommensurable systems. Since the subject is still developing, this article must soon be obsolete. Nevertheless, the discovery and study of incommensurably distorted structures is a milestone in the investigation of structural phase transitions and deserves recording. The explicit inclusion of nonlinear effects such as solitons marks a small but significant step away from the traditional treatment of harmonic or weakly anharmonic systems.

Linear atomic chains have been used to illustrate various phenomena for three reasons. First, it is pedagogically simpler. Second, and purely pragmatically, it is only in one dimension that exact solutions to nonlinear problems, such as the Sine-Gordon equation, are available. Third, and of most interest, many of the systems which are incommensurably modulated are one-dimensional in some sense. This applies particularly to the so-called one-dimensional conducting materials, such as TTF–TCNQ, which have received so much publicity during the past 5 years. In these systems, the observation of diffraction patterns similar to that in Fig. 2*B* is convincing evidence that one-dimensional physics is relevant to the real world.

I thank J. D. Axe, P. C. Hemmer and T. Riste for their critical comments.

The structure of the radio jets in 3C449

R. A. Perley
National Radio Astronomy Observatory, VLA Program, Socorro, New Mexico 87801

Astronomy Program, University of Maryland, College Park, Maryland 20742

High resolution observations of 3C449 show the presence of two highly collimated symmetric jets on each side of an unresolved core. The jets show considerable fine structure and polarisation. Measurements of the depolarisation suggest internal densities of $\sim 0.02\ \mathrm{cm}^{-3}$ and flow velocities of $\gtrsim 1{,}000\ \mathrm{km\ s}^{-1}$.

INCREASING numbers of low-luminosity radio galaxies have been found to contain highly collimated radio jets which connect the central compact nuclear source to the distant outer lobes. Examples of one-sided jets have been found in radio sources such as NGC6251 (refs 1, 2) and 3C219 (ref. 3) as well as double-sided jets such as found in NGC315 (refs 4, 5) and 3C31 (ref. 6). These jets may be the pathways through which the outer lobes of radio galaxies are continuously supplied by fresh relativistic and thermal material from the central nucleus, although whether the jet is composed of separate components[7] or a beam[8] remains controversial. The potential importance of this class of radio source to theories of radio source structure and evolution has led to an extensive programme on the very large array (VLA) to map sources suspected of having radio jets. These observations are being reported elsewhere. Here we present high resolution VLA maps at 20 and 6 cm of the double-sided jet in the radio galaxy 3C449.

3C449 is identified with a cDE4 galaxy[9], the largest in a group of three (VV 6-49-29)[10]. Sandage[11] gives the redshift as $z = 0.0181$ and the visual magnitude as $m_V = 13.2$. With $H_0 = 75$ and $q_0 = 0.5$, 3C449 has a luminosity distance of 72 Mpc, and 1 arc s is equivalent to 340 pc linear extent.

3C449 is a member of the open cluster of galaxies Zw2231.2+3732, which itself is less than 30° from the edge of the Perseus supercluster[12], a system having the same redshift as 3C449.

The first interferometric maps showing the structure of 3C449 were made at 408 and 1,407 MHz[13]. More recent maps[14] at three frequencies made with the Westerbork array have clearly delineated the jet-like structure of this source. As the Westerbork observations did not resolve the jet itself, we have made higher resolution maps of the jet with the VLA at 20- and 6-cm wavelengths. Our new observations show that the jet has a highly complex structure.

Observations

The observations were made with the partially completed VLA. Twelve antennas were used, giving spacings from 250 m to 10 km. Eight of the antennas were placed on the south-west arm while the remaining four were on the south-east arm. Data on the array are given in Tables 1 and 2.

The data were phase and amplitude calibrated against 2200+420 (BL Lac) whose position was taken as $\alpha = 22\ \mathrm{h}\ 00\ \mathrm{min}\ 39.363\ \mathrm{s}$, $\delta = 42°\ 02'\ 08.57''$ (1950) (ref. 15). Three minutes out of every 15 were spent on the calibrator. The flux densities of 2,200+420 were found to be 2.95 ± 0.01 Jy and 3.05 ± 0.03 Jy at 4,885 MHz and 1,465 MHz respectively. These values were derived from simultaneous observations of 1328+307 (3C286), whose flux density at 4,885 MHz and 1,465 MHz was taken to be 7.41 Jy and 14.44 Jy respectively[16].

Because of the unbalanced distribution of antenna positions on the two arms (the south-west arm having antennas out to 10 km, the south-east arm only to 1.6 km) and the declination of

Table 1 VLA systems parameters for observations of 3C449

Band (cm)	Frequency (MHz)	Bandwidth (MHz)	T_{sys}	Date (1978)	Polarisation
20	1,465	50	60°	29 September	Orthogonal linear
6	4,885	50	50°	1 October	Opposite circular

the source, the *u*, *v* plane coverage was non-uniform. In particular, a significant wedge in the *u*, *v* plane was not sampled. The resulting synthesised beam contained significant positive and negative side lobes, and the 'CLEAN' algorithm[17] was used to correct for their effects. Map restoration was done with a gaussian beam of the same half-power beamwidth and orientation as the synthesised beam.

As the shortest spacings at the time of our observations were ~250 m, some large scale structure is absent from our maps, particularly at 6 cm where the maximum fringe amplitude was ~40% of the total flux. Consequently, no 6-cm maps of structure beyond the jets were attempted. None of our maps have been corrected for the weighting due to the antenna power pattern. Since the FWHM of the primary beam at 6 and 20 cm are 9.0' and 30' respectively, these corrections will be quite small.

Structure of the jets

Figure 1 shows our full resolution 20-cm map with a beam size of 4.8 by 3.4 arc s in position angle (PA) −47°. Perhaps the most striking aspect of this source is the nearly perfect mirror symmetry of the jets and outer lobes about an axis through the central nucleus. Each jet is remarkably straight for some 50 arc s from the nucleus before deviating sharply towards the west, dropping in surface brightness and terminating in large diffuse lobes. As both jets bend in the same direction, rotation effects as a cause of this morphology are ruled out.

These large features continue the symmetry of the source; both bend back towards the east as the distance from the nucleus increases. Although both outer lobes are generally diffuse, several features are of interest. Both lobes are relaxed in appearance, which may suggest that they are in static equilibrium (thermally confined) with their surroundings (as opposed to dynamic or ram-confined equilibrium). In the northern lobe the western edge shows a much sharper rise in brightness than the eastern edge, and there seem to be two parallel ridges of emission orientated along PA ~45°. In the southern lobe, a ridge of emission is noticeable on the southeastern edge, roughly parallel to another ridge to the north-west. However, there is a significant chance that these ridges are artefacts of the CLEAN algorithm, as the Fourier components representing them will lie in the unsampled segment of the *u*, *v* plane. Beyond each lobe,

Table 2 Location of antennas

Antenna no.	VLA station no.	Distance from array centre (km)	Azimuth (deg)
1	W8	0.48	236
2	W32	5.22	236
3	E1	0.04	175
4	W16	1.59	236
6	W24	3.19	236

9	W48	10.47	236
11	E8	.48	115
12	E15	1.59	115
13	E12	0.97	115
14	W14	1.26	236
15	W10	0.71	236

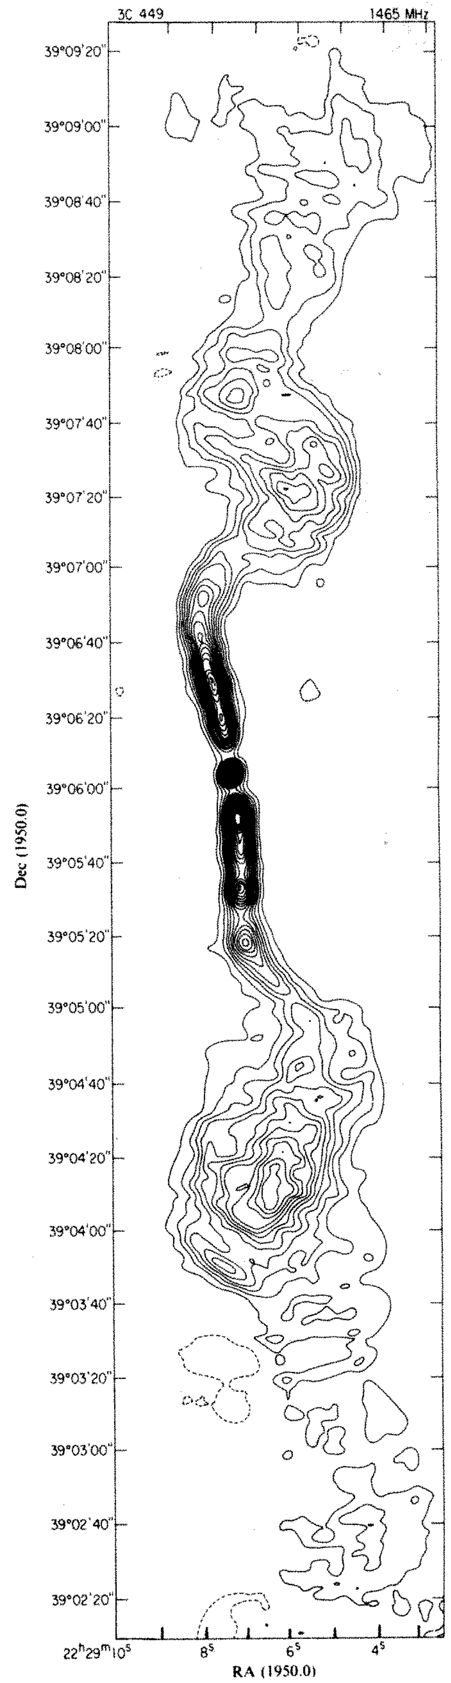

Fig. 1 3C449 at 1,465 MHz as observed by the VLA with a half-power beam of 4.8" × 3.4" in PA −47°. The contour interval is 5% of the peak brightness starting at +5%. The peak brightness on the map is 22.2 mJy per beam area and is located in the southern jet. The beam response is shown by the unresolved nuclear component.

low-brightness emission trails away beyond the edges of the map. A lower resolution map with a beam size of 15″ was made and showed the diffuse emission extending fully 15.8 arc min or 320 kpc with a slight overall curvature towards the west. The Westerbork 49-cm map of Bystedt and Högbom[14] shows low-brightness radio emission whose extension agrees with that seen in our low resolution map.

Returning to consideration of the morphology of the inner jets, we note: (1) within ~10 arc s (3.4 kpc) of the nucleus, both jets are greatly diminished in brightness, although some emission seems still to be present; (2) the southern jet exhibits higher brightness compact condensations. Similar enhancements may also be present in the northern jet although they are not so sharply delineated as the southern ones; (3) the two jets are not quite perfectly opposite each other, but intersect at an angle of 169 ± 2°.

A further map, made at 4,885 MHz, allows us to examine the fine scale structure of the jets. This map, having a resolution of 2.4″ × 1.0″ in PA −40°, is shown in Fig. 2. The high brightness condensations noted above at 20 cm are also apparent at 6 cm. The higher resolution shows that each jet is composed of numerous subpeaks or knots superimposed on a more general ridge of emission. Disregarding the inner 10 arc s low-brightness regions of the jets, straight lines drawn along the axes of the jets do not intersect at the nuclear source but at a point some 1.8 arc s north-west in PA −45°. Finally, the jets steadily widen with increasing distance from the nucleus, at a non-uniform rate. The greatest rate of expansion occurs within ~10–15 arc s from the nucleus where the surface brightness of the jets is minimal. At larger distances the opening angle seems approximately constant. Figure 3 shows the equivalent widths (total area under a cross-section profile divided by maximum height) of the jets measured for our 6-cm observations and corrected for beam convolution, as a function of distance from the nuclear source. Beyond distances of about 15 arc s from the nucleus, data for both jets are well fitted by a constant opening angle of ~7°.

The position of the unresolved nuclear source (< ~0.4 arc s in angular size) was found to be $\alpha = 22$ h 29 min 07.63 s ± 0.01 s, $\delta = 39°\,06'\,03.5'' \pm 0.1''$. Its flux density was 37 ± 1 mJy and 19 ± 1 mJy at 4,885 and 1,465 MHz; thus the nuclear source has a sharply inverted spectrum with $\alpha = -0.55$.

We compared the 6- and 20-cm maps to study spectral index variations along the jets; the results are shown in Fig. 4. The computations were made by comparing 6- and 20-cm maps made with similar resolutions. Although we are missing considerable flux from the 6-cm map due to missing short spacings, the jet brightness distribution, being a small scale feature, will be little affected. The missing structure will tend to make the spectrum even flatter than we have measured. In the main lobes, however, so much brightness is absent that no attempt was made to calculate the spectral index for these features. The average spectral index in the jets is 0.65 ± 0.1 in the north jet and 0.5 ± 0.1 ($S_\nu \propto \nu^{-\alpha}$) in the south jet. Some evidence for steepening of the spectrum is noted towards the ends of each jet although, curiously, the spectrum of the southern jet seems to be flattest at a distance of ~35 arc s from the nuclear source.

The jets are highly polarised at 6 cm, averaging ~30% along their lengths, although the southern one is somewhat less polarised than the northern one. A plot of the percentage polarisation and measured **E**-vector PA is shown in Fig. 5. The typical **E**-vector PA is 160° and changes rather little throughout the length of the jets. Haves[18] found the rotation measure of the integrated polarised flux to be -170 ± 4 rad m^{-2}. If this rotation measure is entirely external and applies to the jets, the intrinsic direction of the projected jet magnetic field is found to be 105°, that is, perpendicular to the jets to within our measurement errors. However, the polarised flux from the outer lobes must make a strong contribution to the total polarised flux and we must be wary of how representative Haves' rotation measure is in the vicinity of the jets, although a large negative rotation measure is characteristic of the galactic coordinates of 3C449 (ref. 19) ($l = 95°$, $b = -16°$). If our derived orientation of the projected magnetic field is correct, then the most likely intrinsic structure is that of a circumferential field.

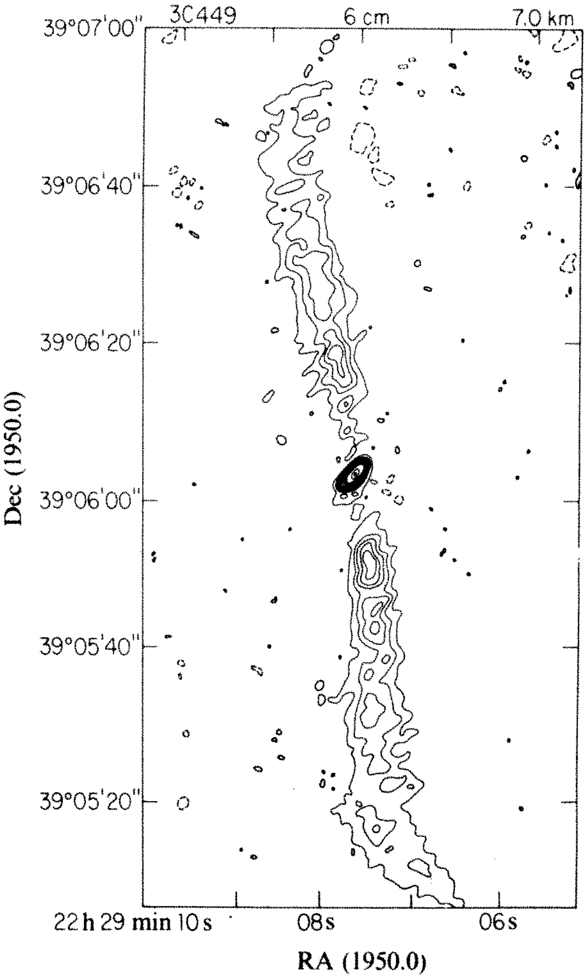

Fig. 2 The high resolution, 4,885 MHz map of the jets in 3C449. The synthesised beam is 2.4″ × 1.0″ in PA −40°. The contour interval is 1.5% of the peak brightness, starting at 1.5%, and the brightest contour is at 13.5% of the peak brightness, which is 37 mJy per beam area. The beam is shown by the nucleus, a 50% contour has been added to delineate the half-power beamwidth.

Discussion

We calculated equipartition parameters for the outer lobes and the jets using the standard formulae[20] but modified to derive the parameters directly from the measured integrated (over frequency) surface brightness, I, and path length through the emitting volume, s, rather than radio luminosity and source volume. The resulting field strength is given by

$$H_{\min} = \left[6\pi K \frac{I}{s} \frac{(1+k)}{|\sin\theta|^{3/2}}\right]^{2/7} \qquad (1)$$

and the total energy density in particles and fields is

$$\mu_{\min} = \frac{1}{24\pi}\left[6\pi K \frac{I}{s} \frac{(1+k)}{|\sin\theta|^{3/2}}\right]^{4/7} \qquad (2)$$

where k is the ratio of the energy in protons to electrons, and K is equal to $[c_2 c_{12}(\gamma)/c_1 c_3 c_8(\gamma)]$. The c-factors are defined and tabulated by Pacholczyk[20] and are functions of γ, the energy index of the assumed power law distribution of relativistic electrons. γ is related to the spectral index by $\gamma = 2\alpha + 1$. The angle θ is measured between the line of sight and the direction of the (assumed uniform) magnetic field.

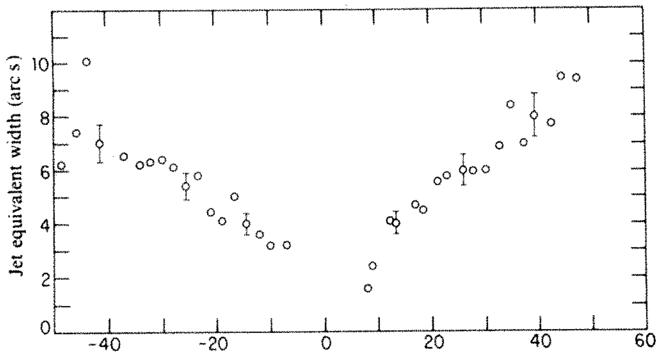

Fig. 3 The equivalent width of the jets found by planimetry of the 6-cm map shown in Fig. 3. The error bars shown are estimated from the noisiness of the corresponding profiles.

Our equations (1) and (2), combined with our 6- and 20-cm measurements of the intensity, give the magnetic field and total energy densities displayed in Table 3. The following assumptions have been made: (1) cylindrical geometry with the jet axis perpendicular to the line of sight, so that the path length through any feature is equal to the observed width of that feature. For the jets, we have taken the path length to be double the equivalent 6-cm width. This is appropriate for brightness distributions which are highly peaked at the centre (and is exactly true for a triangular brightness distribution). Our 6-cm profiles of the jet clearly show the brightness is in fact strongly peaked at the centre, and is not at all limb brightened, as may be expected for emission from a cylindrical sheath surrounding the jet. However, note that this observation is not conclusive evidence for emission from a filled cylinder, as emission from a circumferential magnetic field geometry (the configuration implied by the polarisation measurements) will appear centre brightened for virtually any distribution of the emitting gas due to the highly directive emissivity of synchrotron radiation. (2) The magnetic field lines are perpendicular to the line of sight through the centre of the feature, so that $\sin\theta = 1$. Note that if the field is purely circumferential, this requirement is automatically satisfied whatever the orientation of the jet may be, whereas if the magnetic field is longitudinal, our assumption requires the jet axis to be perpendicular to the line of sight. (3) The spectral index in the jet is 0.5, and 0.7 in the lobes. (4) The integration over frequency is from 10 MHz to 10 GHz. (5) Equal energies in relativistic electrons and protons ($k = 1$).

Note that the equipartition values of the internal energy density in the lobes ($\sim 5\times10^{-12}$ erg cm^{-3}) is approximately equal to the thermal particle energy density (nkT) in the intracluster medium of x-ray clusters of galaxies. Since 3C449 is located in a cluster of galaxies (albeit a poor one) and since HEAO 1 data[21] demonstrate that poor clusters can also contain X-ray emitting gas, it seems that the radio lobes may be statically confined by external thermal pressure. The diffuse trailing emission is then interpreted as gas rising out of the intracluster medium through buoyancy forces, the overall symmetry of the large scale features being due to the central location of 3C449 in the cluster.

Table 3 shows that in both the northern and southern jets the quantity BR is approximately constant, where B is the magnetic field strength and R is the path length through the jet. This result implies that $B \propto r^{-1}$, where r is the cross-sectional radius of the jet, as suggested by Blandford and Rees[8] for a jet with a circumferential field. A similar result was found by Readhead *et al.*[2] for the jet in NGC6251, and it would be interesting to measure the orientation of the magnetic field in that source.

We now consider depolarisation within the jets. They have a typical degree of polarisation of ~30% and, since the electric vectors are quite uniform, it seems that beam depolarisation is unlikely at 6 cm. Thus we must inquire whether the observed degree of polarisation indicates the intrinsic degree of ordering of the magnetic field or whether significant depolarisation due to thermal matter in the jet has already occurred at 6 cm. We first consider the latter possibility and note that Westerbork 21-cm observations of the jet in NGC315 (ref. 5) show that jet to have an intrinsic degree of polarisation of up to 60%. Adopting this value as a possible intrinsic polarisation for 3C449 and using the simple slab depolarisation model of Burn[22] we find a rotation measure internal to the jet of $\sim|500|$ rad m^{-2}. If the path length is ~3.4 kpc then $nH_z \sim 1.8\times10^{-7}$ cm^{-3} G, where n is the thermal matter density and H_z is the line of sight component of the magnetic field. $H_z \lesssim \sim 10^{-5}$ G (Table 3) so $n \gtrsim \sim 0.02$ cm^{-3}. An internal rotation measure of $\sim|500|$ rad m^{-2} would imply that the average degree of polarisation in the jet at 21-cm wavelength is only ~4% if the slab model means anything. The unpublished 21-cm Westerbork observations of Bystedt and Högbom show the jet polarisation to be ~4%, a value in agreement with what we find.

The low 20-cm polarisation may be due to differential galactic Faraday rotation across the 20-cm WSRT beam. This would require a gradient in the rotation measure of ~50 rad m^{-2} over an angular scale of 35″. This is an extremely large gradient, and although no information on rotation measure gradients over this angular scale is available, we regard this explanation for the low 20-cm polarisation as unlikely. The issue will only be settled by high resolution 20-cm polarisation measurements of the jet—planned for late 1979.

We consider now the possibility that the 6-cm 30% polarisation of the jets represents the intrinsic degree of polarisation. In that case a considerable amount of energy is stored in a random magnetic field. Since the 21-cm degree of polarisation is ~4% (ref. 14) there is strong depolarisation by 21 cm. In fact, 21-cm polarisation divided by intrinsic polarisation equals 0.13 and, with this large depolarisation, the rotation measure could be any of several values as we could have gone through the first minimum of the $\sin\chi/\chi$ depolarisation curve appropriate for a simple slab. However, the minimum acceptable rotation measure is $\sim|75|$ rad m^{-2}, which implies $nH_z \gtrsim 3.4\times10^{-8}$ G cm^{-3}. The uniform component of magnetic field is, in this case, $\lesssim \sim 5\times10^{-6}$ G so $n \gtrsim \sim 0.004$ cm^{-3}. This limit for the thermal density is not greatly different from that found for the previous case, and since $|75|$ rad m^{-2} is a minimum rotation measure, we adopt an internal thermal density of 0.02 cm^{-3}. This value is in good agreement with the density derived for the jet in 3C31 from dynamical arguments[23]. Since the 3C449 jets seem to have a large internal rotation measure, the integrated rotation measure[18] may not affect the direction of the jets and our derived magnetic field direction cannot yet be considered definitive.

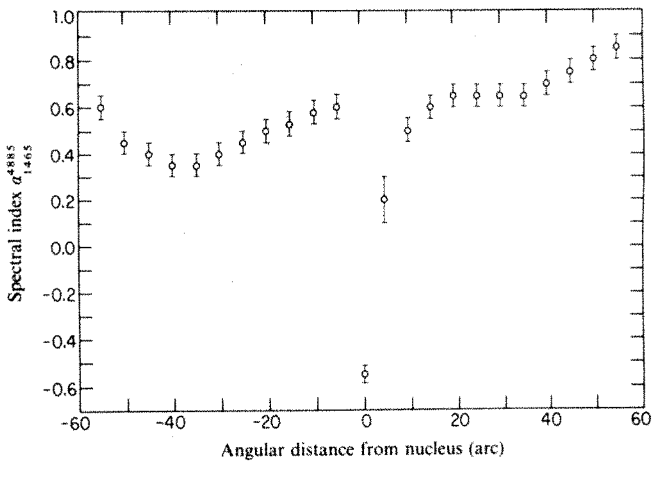

Fig. 4 The measured spectral index of the jets, defined through $S_\nu \propto \nu^{-\alpha}$. The error bars are estimated from the noise in the data, and do not include the possible effects of unmeasured brightness components. The effect of such components will be to lower generally the measured values of α.

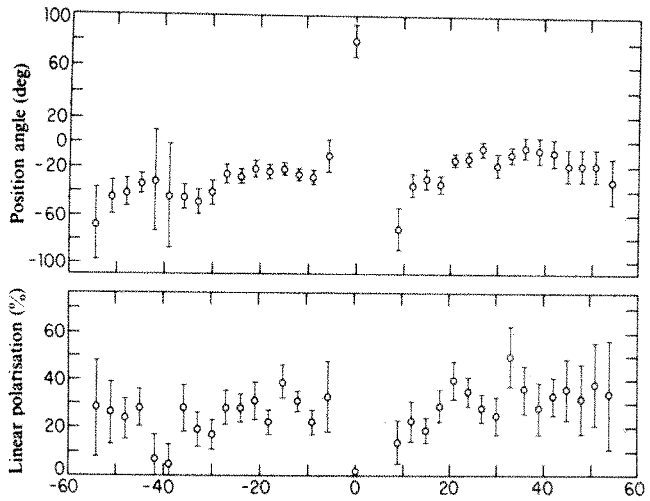

Fig. 5 The percentage and position angle of linear polarisation in the centre of the jets in 3C449 at 6 cm. In this case, the errors have been calculated using the law of propagation of errors from the observed errors in the Stokes parameters *I*, *R*, and *U*. The systematic error due to the polarised side lobes of the VLA antennas has not been included; however, these errors are negligible as they are <1% within the angular extent of the jets.

At distances greater than ~10 arc s from the nucleus the jets expand with a uniform opening angle of ~7°. If the jet is free (not confined by a surrounding medium), the transverse expansion will be at approximately the generalised sound speed, $(\mu/\rho)^{1/2}$, where μ is the internal energy density and ρ is the mass density. A lower limit to the internal energy density in the jet is given by the energy density in relativistic particles and fields, $\sim 7\times 10^{-1}$ erg cm^{-3} (Table 3) while we estimated ρ to be $\sim 3.3\times 10^{-26}$ g cm^{-3} from the depolarisation calculations. The resulting sound speed is ~150 km s^{-1}. From the opening angle, we find a Mach number of 8(= cotan 7°) which implies a flow speed of ~1,200 km s^{-1}. This velocity compares favourably with the flow velocity in the jet of 3C31 derived on the basis of dynamical arguments[23]. Furthermore, this value is comparable to that suggested[24] for the velocity at which material is ejected from the nucleus of the head-tail galaxy NGC1265.

Our estimate of the flow speed depends on the assumption that the transverse expansion is at the internal sound speed, C_s. We note that in an expanding jet, C_s will decrease with increasing distance from the nucleus as the flow becomes more ordered. Thus the lateral expansion must be at least C_s, and so our derived flow speed is a minimum. Furthermore, if the jet is thermally confined, the flow speed will be higher than for a free jet of the same width.

The decline of the internal sound speed with distance from the nucleus may be expected to cause a decrease in the jet opening angle with distance. Note that such a curvature may be occurring in the inner 10″ of each jet, as seen in Fig. 3.

Further evidence for flow speeds of the order we have estimated is given by the changes in the spectral indices along the jets (Fig. 4). The steepening of the spectrum seen at distances greater than ~35 arc s from the nucleus indicates (from synchrotron ageing arguments)[20] that the age of the jet at this point is $\sim 1.1\times 10^{7}$ yr. This distance then translates into a velocity of 800 km s^{-1}. Considering the uncertainties in these types of calculations, we feel that this value is in good agreement with our previous estimates.

The flow speed of ~1,000 km s^{-1}, combined with a mass density of 3.3×10^{-26} g cm^{-3} gives a mass flow of 2×10^{26} g s^{-1}, corresponding to 3 $M_\odot$ yr^{-1}. This mass flow corresponds to an energy flow of 1.5×10^{42} erg s^{-1}, a quantity which exceeds the directly visible energy flow in relativistic material by a factor of ~20, and which may be a significant source of energy available for production of relativistic matter in the outer lobes.

We have previously noted that each jet bends towards the east before terminating in large, diffuse lobes, and that these parallel bends rule out rotation of the nuclear source. It may seem attractive to invoke the radio-trail hypothesis[25] to explain these bends, but because the lobes bend back towards the axis defined by the jets, this hypothesis seems unlikely. Rather, the similarity of the structure of 3C449 to that of 3C31 (ref. 6) suggests that the gravitational encounter hypothesis of Blandford and Icke[23] would be more successful in explaining the bends in 3C449. In this hypothesis, Blandford and Icke have had at least partial success in explaining the symmetry of 3C31 by invoking a gravitational interaction between 3C31 and a nearby companion. Since 3C449 has two companions[26] located within 100″, the symmetry in this source may be due to a similar interaction between one or both.

Beyond the large lobes, the emission is seen to trail away with a small but distinct curvature towards the west. This structure is reminiscent of the general structure of radio tail galaxies, and it is worth noting other similarities between 3C449 and radio tail galaxies such as 3C83.1B (NGC1265). The luminosity of 3C449 is typical of radio tail galaxies, and the observation that the compact structure of 3C449 is located close to the optical galaxy is also similar to NGC1265. Also, our derived flow speed (~1,000 km s^{-1}), mass flow rate ($\sim 3M_\odot$ yr^{-1}) and ratio of bulk kinetic to relativistic energy (20 : 1) agree with theoretical values taken from the fit of the plasmoid model[27] of radio tail galaxies.

There is increasing observational evidence that gaps near the nuclear source seem to be a common property in radio jets, having been observed in several radio sources (for example, NGC 1265[28], NGC 315[5] and 3C219[3]). The typical physical separation is usually several kpc. At present we can only suggest some explanations. The gaps may represent the intervals between major outbursts. The typical separation between major peaks in the 3C449 jets is 3.4 kpc, corresponding to $\sim 3\times 10^{6}$ yr with our previously estimated flow speeds. This time interval between major outbursts is in good agreement with that calculated[24] for NGC1265. Another suggestion is that the material flowing from the nucleus is initially very highly collimated so that synchrotron radiation is inhibited by a small pitch angle between the particles and magnetic field. This suggestion implies that close to the nucleus the magnetic field should be parallel to the jet. VLA observations of 3C31 and NGC315[29] suggest that this configuration may indeed prevail. Alternatively the magnetic field could be much lower than the equipartition value (a decrease by a factor of 20 would suffice to produce the observed drop in brightness). If either of the last two suggestions holds true, then some agency, possibly turbulence, is required to randomise the particle pitch angles or amplify the magnetic field strength, or both, by the time the material has travelled several kpc from the nucleus.

This latter suggestion may relate to the changes in spectral index and 6-cm degree of polarisation along the jets (Figs 4 and 5). In the northern jet, the spectrum continually steepens as the distance from the nucleus increases; at the same time, the degree of polarisation steadily increases, which would indicate an increasingly ordered magnetic field. The spectrum of the southern jet flattens over the distance 0–35″ from the nucleus while the degree of polarisation apparently decreases over this

Table 3 Equipartition values of magnetic field and total energy density at selected points in 3C449

Site	Emissivity* I/S (erg s^{-1} cm^{-3} sr^{-1})	$H_{\min}$ (μG)	$\mu_{\min}$ (erg cm^{-3})
Southern Lobe	4.5×10^{-29}	7.3	4.9×10^{-12}
Northern Lobe	3.8×10^{-29}	7.0	4.5×10^{-12}
Southern Jet 40″ S	2.1×10^{-28}	8.1	3.9×10^{-12}
Southern Jet 15″ S	6.8×10^{-28}	11.2	1.2×10^{-11}
Northern Jet 15″ N	5.6×10^{-28}	10.6	1.0×10^{-11}
Northern Jet 35″ N	1.6×10^{-28}	7.4	5.1×10^{-12}

* From 10 MHz to 10 GHz assuming a power law spectrum of index 0.5 for the jets and 0.7 for the lobes.

distance, although the errors are large. Thus the magnetic field in the southern jet apparently becomes increasingly disordered. This disordering might be due to turbulence which then might also be responsible for transferring energy to the relativistic electrons[27] and thus for flattening the observed radio spectrum.

Conclusions

The low-luminosity radio galaxy 3C449 exhibits great variation of structure. Two compact, well collimated, and nearly symmetric jets are found to issue from an unresolved core which is optically thick at 6 cm and coincident with a cDE4 optical galaxy. The radio jets are not smooth in appearance, showing a lumpy and somewhat turbulent structure. The jets are not seen within 10″ (~3 kpc) of the central core, but appear to 'turn-on' at this distance. Each jet widens steadily beyond the turn-on point, and gradually diminishes in brightness until each makes a sharp bend to the west and terminates in large, diffuse blobs with very relaxed appearance. Trailing emission up to ~8′ from the centre is detected.

The spectrum of each jet is flatter than normal, with the spectral index averaging near 0.6. Little trend in the index is seen, although the southern jet may flatten slightly towards the end. Both jets are highly polarised, with percentage linear polarisation varying generally from 20 to 40%. The position angle of the polarisation is nearly constant throughout each jet. If all, or most, of the Faraday rotation is external, then the inferred jet magnetic field is circumferential. However, a significant portion of the rotation measure may be due to internal thermal matter as WSRT observations of the jet show low polarisation. If this depolarisation is due to internal Faraday rotation, the inferred electron density is $\sim 0.02\ \text{cm}^{-3}$. Combining this mass density with minimum energy densities derived from standard equipartition arguments, a minimum flow speed of $\sim 1{,}000\ \text{km s}^{-1}$ for a free jet is found.

We thank J. Bystedt and J. Högbom for permission to use their data before publication, and J. O. Burns for useful comments. A.G.W. acknowledges support from the NSF under grant AST 77-22906.

Jupiter's rings

Voyager 2 observations of the jovian ring system discovered by Voyager 1 are presented. The rings were observed both above and below the jovian equatorial plane and at extremely low and high phase angles. This ring system seems to represent a steady state configuration for small particles that are slowly moving in toward Jupiter. It must be resupplied from sources well outside Roche's limit.

JUPITER'S ring system was discovered on 4 March 1979 by Voyager 1 as a result of a deliberate search as the spacecraft passed through the equatorial plane of the planet[1]. Having established the existence and outer dimension of a jovian ring system, Smith *et al.* worked with the Voyager engineers to develop new imaging sequences for the Voyager 2 encounter with Jupiter during early July. The major goal of these sequences was to make observations slightly out of the ring plane, in order to establish the number of ring components present, their dimensions and relative brightness. Several filters were used to establish the colour of the ring particles. A summary of Voyager's jovian ring data set is given in Table 1. Figure 1 illustrates the geometry and times at which Voyager 2 data were taken with respect to the flyby trajectory.

Data description

The first set of newly sequenced images was obtained on 8 July at an inclination of 2.5° to the ring plane on the inward leg of the trajectory. These data were the first to reveal both sides of the ring as seen in Fig. 2. This view confirmed that the jovian ring was very faint and showed no obvious gaps. The brightest segment of the ring in Fig. 2 was found to be $\sim 3\times 10^{-5}$ of the mean brightness of Jupiter at zero degrees phase angle. These data were smeared by relative spacecraft motion (apparent in the star trails recorded in 96-s exposures).

The next set of images was obtained 14.5 h later as the spacecraft passed through the planet's equatorial plane. Because of image motion, these pictures did not immediately add to the information already available from Voyager 1, but they confirmed the existence of a sharp outer edge for the ring system (Fig. 3). This boundary has been remeasured on the Voyager 1 image and has a value 1.8 R_J (128,500 km from the centre of Jupiter).

All of these observations (including the Voyager 1 picture) were obtained at rather small phase angles; the rings were visible because of light scattered back towards the camera. At the time of the Voyager 2 encounter the Sun was in Jupiter's equatorial plane with about two thirds of the solar disk below (south of) the ring plane as seen from Jupiter.

0028-0836/79/410442—05$01.00

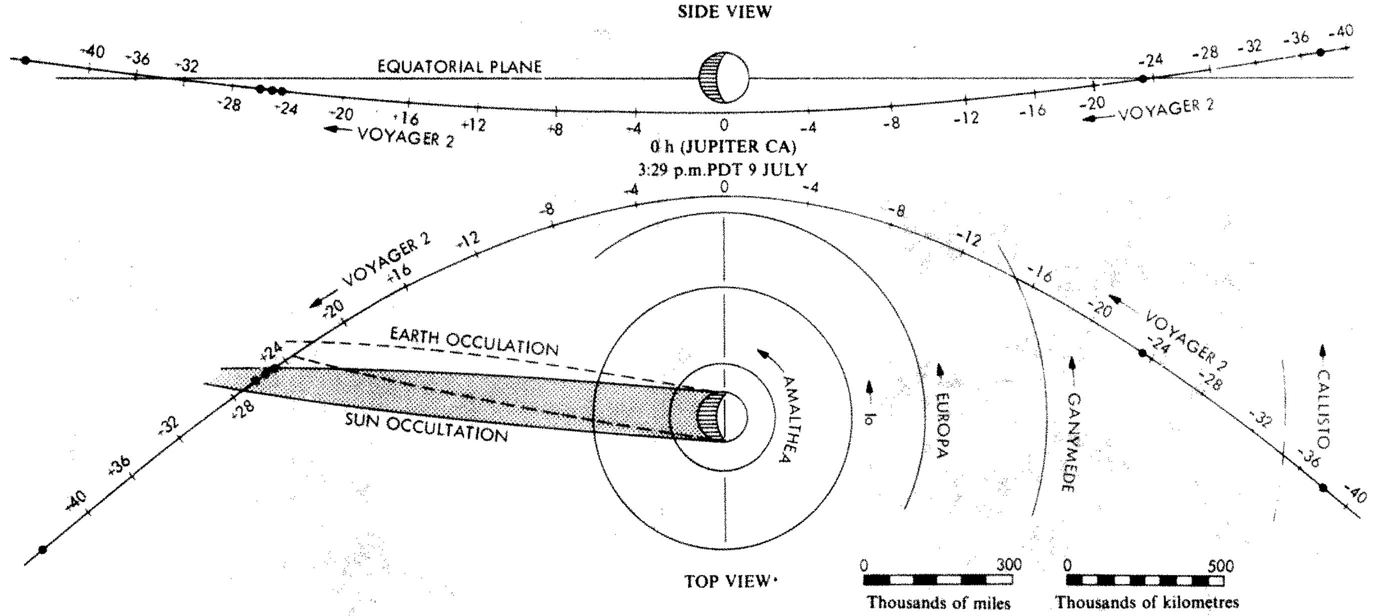

Fig. 1 The Voyager 2 spacecraft's Jupiter flyby trajectory is shown in two views. Each of the sets of pictures targeted for the rings is shown by the symbol ●. The time of closest approach for Jupiter was 11.21 UT 9 July 1979 (4.21 p.m. PDT 9 July). The range at closest approach was 10 R_J.

Twenty-six hours after closest approach to Jupiter, the spacecraft was in Jupiter's shadow approximately two degrees below the ring plane. The pictures taken in these illumination conditions at very high phase angles, resulted in the spectacular images shown in Figs 3, 4, 5, 6 and 7. Close inspection of the complete set of pictures indicates that there are at least four distinct components in the jovian ring system:

(a) a narrow bright segment about 800 ± 100 km wide, inner edge 1.7 R_J;

(b) a fainter segment about 6,000 km wide, inner edge 1.68 R_J;

(c) A very faint inner 'ring' that appears to be a continuous sheet of dispersed material probably extending all the way to the planet;

(d) an even fainter outer edge of small particles that extend to 1.8 R_J and slightly beyond.

Each of these components is designated in the intensity plot of Fig. 8. The intensity plot was taken normal to both sides of the ring halfway between the visible end of the ring and Jupiter.

Note that the jovian ring system is thus closer to its parent planet than either of the rings of Saturn (outer edge of ring A = 2.28 R_S) or the rings of Uranus (outer edge of ring ε = 2.1 R_U). On the other hand, the width of the jovian ring is intermediate between the extremely narrow rings of Uranus (<100 km) (ref. 2) and the broader rings of Saturn (17,000–25,000 km).

Steady-state rings

We favour the following hypothesis for the origin of the rings and their maintenance: namely, that the rings seem to represent a steady-state configuration for small particles moving in towards the planet in orbits near the equatorial plane. The particles are supplied from sources outside the Roche limit which could include cometary and meteoritic debris, impact ejecta from the inner satellites, and volcanic ejecta from Io. Evidence of loss from the ring is apparent from the observed distribution of particles inside the bright segment, ring (c). Among the loss mechanisms to be considered we note the Poynting–Robertson effect both from direct sunlight and that reflected by Jupiter, but interactions with the jovian magnetic field and the environment of charged particles are probably more important. Braking by the jovian magnetic field (which is moving more slowly than particles in the ring) will cause charged grains to move inwards. The high energy ions in the jovian magnetosphere will sputter material from them, causing the particles to get smaller and thus enhance the previously mentioned braking mechanisms.

Preliminary analysis

A rough estimate of the mean particle size in the jovian rings can be obtained from the phase function manifested in the strong forward scattering. In the narrow angle frames, it is evident that the arm of the rings closer to the spacecraft is less bright than the farther one. This is shown in Fig. 8 where a plot of relative intensity is shown for both the near and far sides. This set of data represents a difference in scattering angle of ~0.3°. Inspection of intensity contours for single particle scattering[3] suggests that for this condition to exist, the size parameter $X = 2\pi a/\lambda$ must be about 50. Adopting $\lambda = 0.497$ μm as the effective wavelength of the narrow angle camera with the clear filter (a clear quartz substrate) we find that the mean particle radius is in the range of 4 μm. This estimate is also supported by comparing the brightness of the scattering at this high phase angle with that obtained near opposition. The Voyager 2 data show that the rings are approximately 20 times brighter in the diffraction lobe than in backscattering. (Note: the actual maximum value of this difference must be greater still.)

It is also evident from colorimetry based on comparisons of images taken through violet, orange and green filters that the light diffracted towards the spacecraft by the ring particles at phase angles near 180° is distinctly reddish compared with sunlight (the ratio of orange to violet is 1.7–1). This suggests either blue absorption by the particles or wavelength-dependent forward scattering (diffraction). At this stage, it is not possible to determine which of the two causes is dominant. Note that low

† The angle of the spacecraft above or below the jovian ring plane.

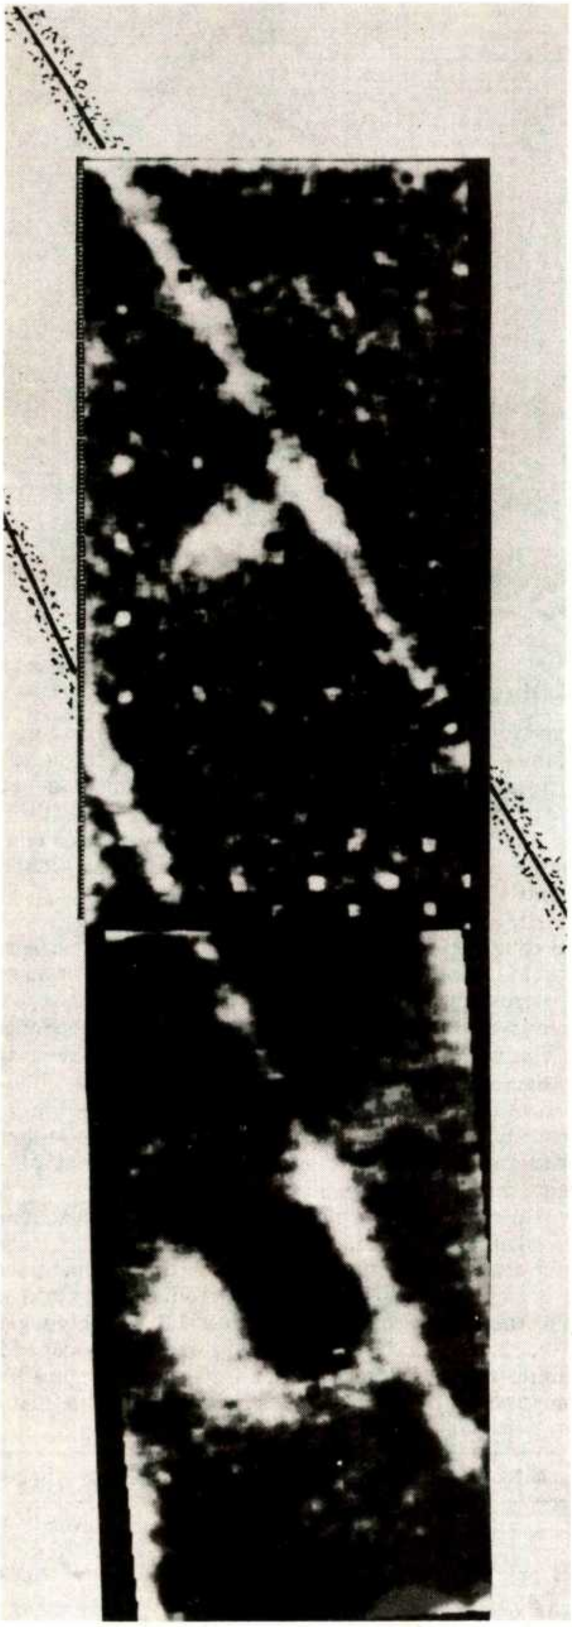

Fig. 2 Both sides of the jovian rings are apparent in this two picture mosaic returned by Voyager 2. These data were taken at a range of 2×10^6 km when the spacecraft was approximately 2.5° above the ring plane. The data were submitted to an extreme contrast enhancement to bring out this faint signal. The blotchy areas around and between the rings are artefacts of this extreme enhancement.

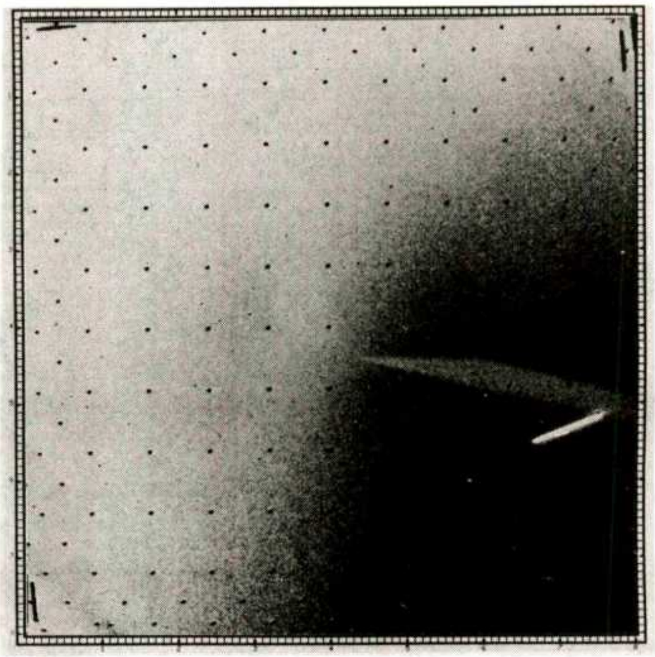

Fig. 3 This Voyager 2 picture caught the sharp outer edge of the ring as the spacecraft passed through the ring plane at a range of 1.4×10^6 km from Jupiter. The bright star trail shows the relative spacecraft motion which smeared the picture in this 96-s exposure through the clear filter. This was one of a set of nine pictures targeted at this time.

reflectivity of blue light is consistent with the low blue albedos of all five large jovian satellites (especially JV and JI) and most asteroids and meteorites[1,4,5]. The colour by itself, however, is not diagnostic of composition.

Resonance commensurabilities

The existence of a well-defined outer boundary for the rings suggests a decrease in the drag force acting on inward evolving particles moving into this general region. The fact that the brightest segment of the ring (a) is at this outer boundary simply reinforces this impression. There are two near commensurabilities between the period of particles at the ring's outer edge and fractional periods of jovian satellites:

$$\tfrac{3}{5}p_{\text{Amalthea}} \text{ and } \tfrac{1}{6}P_{\text{Io}} \text{ (in days: } P_{(\text{a})}=0.291,\ \tfrac{3}{5}P_{\text{v}}=0.299,\ \tfrac{1}{6}P_{\text{I}}=0.295)$$

These near commensurabilities do not seem particularly compelling, as the mass of Amalthea is very small ($\sim10^{21}$ g if $\rho=3.4$) and 1/6 is a small fraction of Io's period. For comparison, the outer edge of Saturn's A ring falls close to a 2/3 resonance with Mimas, while particles in Cassini's Division would have approximately half the period of Mimas, but even there the agreement is not perfect[6]. Note that if Amalthea were considered to have a role equivalent to Mimas for the Jupiter system, the entire (a)+(b) complex falls well inside the boundaries set by the 1/2 and 2/3 resonances. It may be that in the Jupiter system the satellite resonances only serve to modulate other effects, for example, a balance between electrostatic and gravitational forces.

Relation to Roche limit

In any case, the rings are well inside the classical Roche limit for the breakup of a liquid satellite (2.44 R_{J}) and also within the limit set by the mutual gravitational attraction between two particles with mean densities differing from that of Jupiter:

$$r = R_{\text{J}}\left(16\frac{\rho_{\text{J}}}{\rho_{\text{P}}}\right)^{1/3}$$

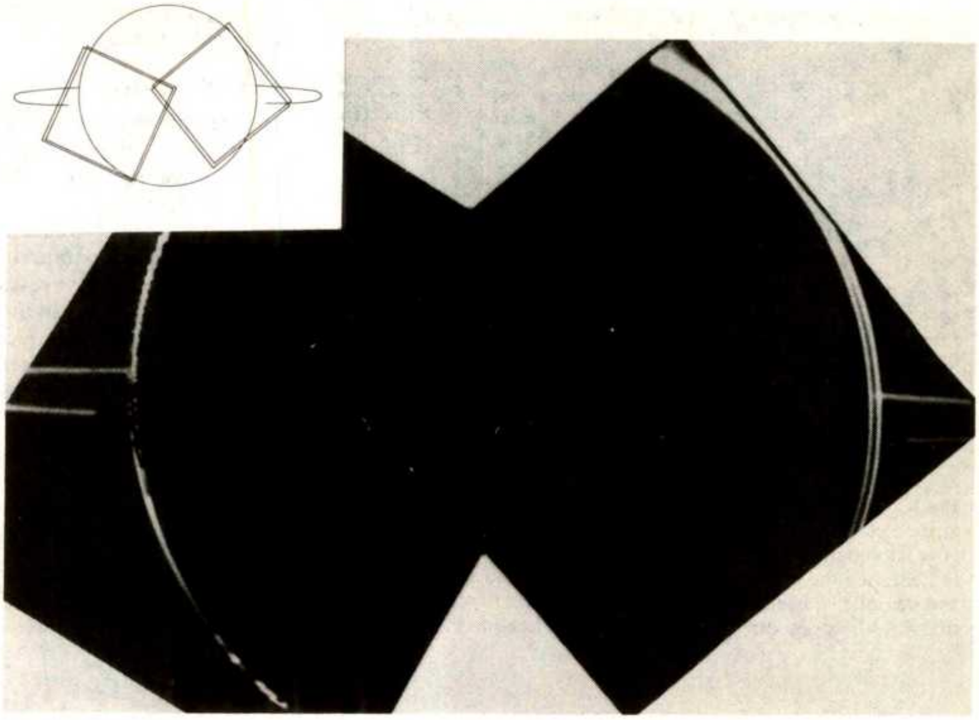

Fig. 4 This mosaic was taken while the spacecraft was in Jupiter's shadow at a range of 1.45×10^6 km. These pictures were taken with Voyager 2 spacecraft's wide angle cameras through the violet filter. The limb of Jupiter and the rings are clearly revealed in these high phase angle pictures as a result of forward scattering from a haze layer high in Jupiter's atmosphere.

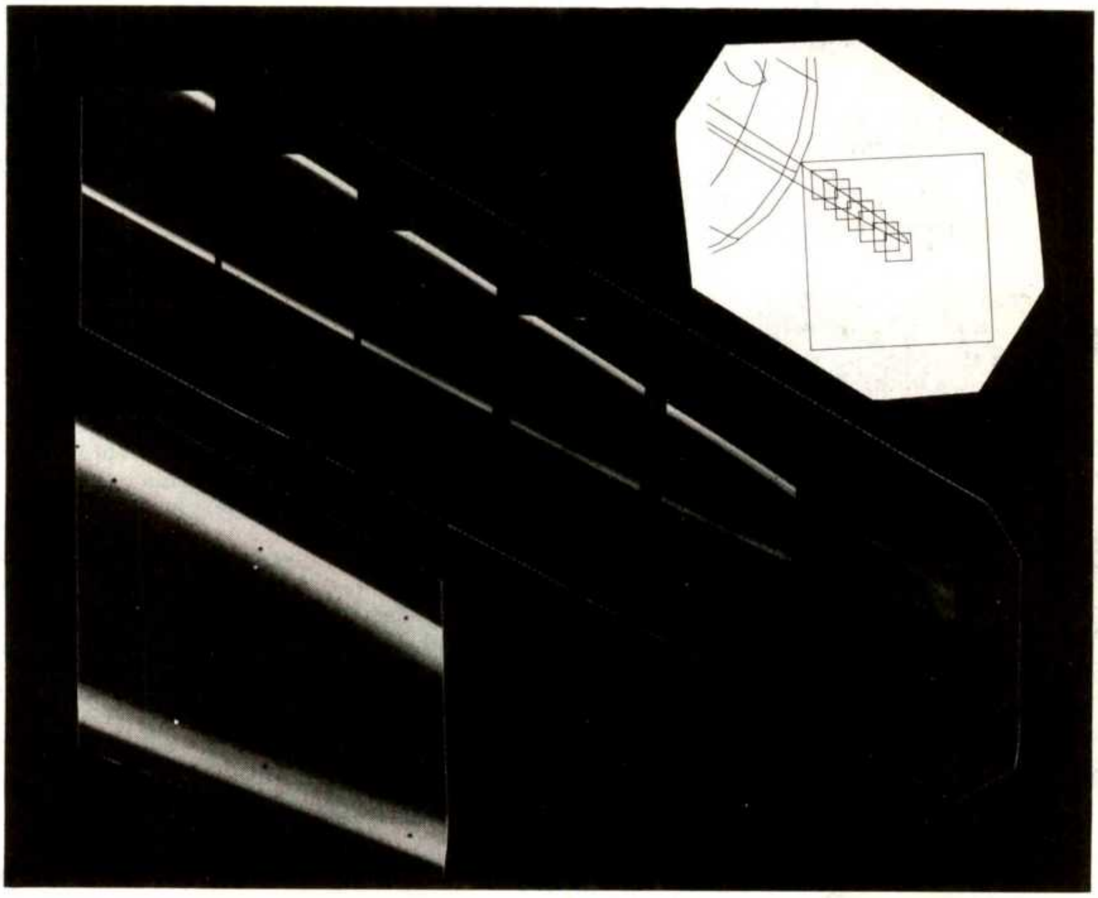

Fig. 5 This six picture narrow angle sequence was taken at high phase angles while the Voyager 2 spacecraft was in Jupiter's shadow. The line drawing in the upper corner illustrates the targeted fields of view predicted for this picture-taking sequence. These data were edited onboard the spacecraft to preserve the signal-to-noise ratio required to send them back in real time (which accounts for their rectangular shape and the loss of overlap). The picture on the lower left has been enlarged to illustrate the presence of material between the bright arms which forms a continuous sheet that may extend all the way to the planet. The star trail shown gives a history of the smear during this 96-s exposure.

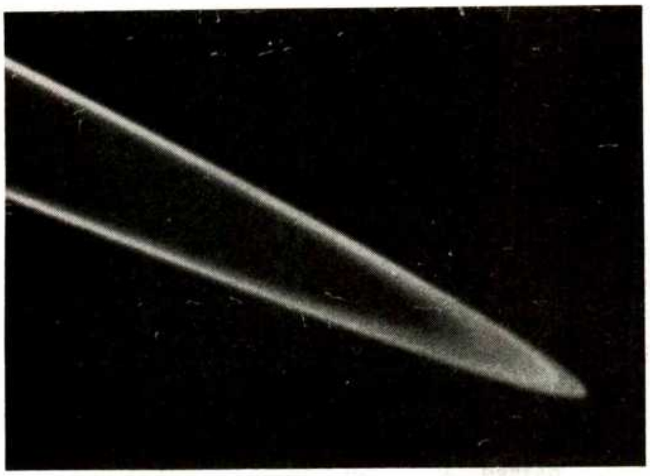

Fig. 6 This wide angle picture was taken at the end of the narrow angle picture sequence in Fig. 5. It shows the bright, sharp outer edge, along with the fainter inner continuous sheet of particles (ring (c)) between the edges. This picture had an exposure time of 15 s and was taken through the clear filter. The spacecraft was at a range of 1.4×10^6 km in Jupiter's shadow about 2° below the plane of the ring.

Adopting $\rho_p\approx2.6$ (for example, meteoritic material) $r=2\ R_J$. On the other hand, if Amalthea represents a high temperature condensate that continues the density gradient from JIV to JI, it might have a density as high as 3.5, the mean density of Io. Fragments of this satellite in the ring would then lead to $r=1.81\ R_J$, close to the observed outer radius. As the particles in Saturn's rings evidently consist mainly of water ice, this gravitational constraint suggests that one reason Jupiter's rings are so close to the planet may be that the ring particles have a higher mean density than the particles in the rings of Saturn.

The limit for the breakup of a solid body with a diameter larger than 30 km and a very low tensile strength (10^6 dyn cm^{-2}) has been calculated by Aggarwal and Oberbeck[7] to occur between 1.35 and 1.38 R, well inside the observed dimensions of the (a) and (a)+(b) components of the ring ($1.68-1.77\ R_J$). Hence, there is no reason to assume we are looking at fragments from a disrupted satellite.

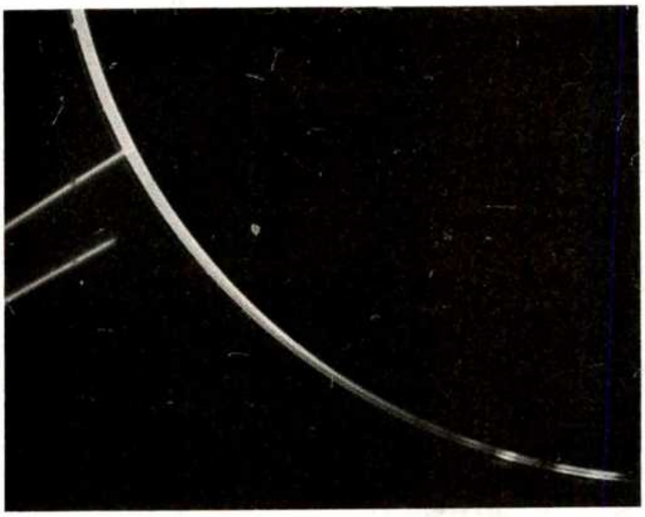

Fig. 7 A black and white reproduction of a colour composite which was made from a violet and orange frame taken with the wide angle camera. These are the same data as shown on the left in Fig. 4. The jovian ring system is two light orange lines protruding from the left along with the very faint orange materials in between them. The edge of the ring closest to the spacecraft has been cut off by Jupiter's shadow. The spacecraft was approximately two degrees below the ring plane. The very colourful multiple images of the Jupiter limb are evidence of image smear during these long exposures (96 s).

Conclusions

Before this discovery, Pollack[8] suggested that a ring around Jupiter was unlikely because original particles left over from the planet's accretion would have been quickly lost by gas drag and ice particles would not have condensed late in the accretion ring dissipation stage because Jupiter would have been too hot. Our model for a steady-state ring is entirely consistent with this point of view. It is now necessary to define the sources, sinks and stabilising influences in more detail.

Further study of the pictures of Jupiter's ring should give an improved assessment of the scattering properties and hence average size of the ring particles. The dimensions for the ring components stated here will be refined and the degree to which the ring approaches a perfect circle will be determined with the help of the images of stars recorded on individual frames. Unfortunately, we will not be able to improve the crude upper limit of 30 km placed on the ring thickness by Voyager 1, as the images obtained at ring-plane crossing with Voyager 2 do not give any better resolution.

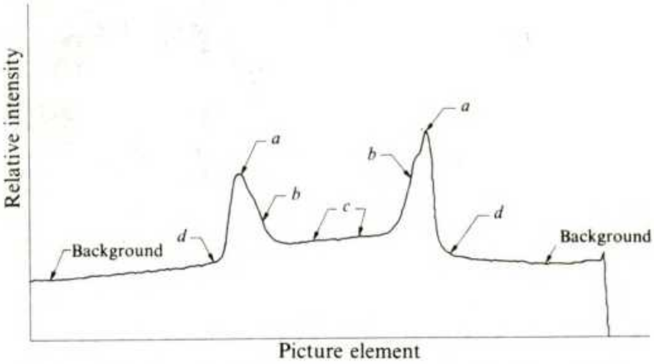

Fig. 8 This plot of relative intensity illustrates the difference in brightness and resolution between the near and far edge of the rings. These data were taken perpendicular to the ring at about 1.4 R_J. This narrow angle frame is part of the mosaic in Fig. 5 taken through the clear filter. It shows a ratio of ~1.43 for the brightest part of each side of the ring plotted in this intensity profile. This plot also clearly shows each of the four components of the jovian ring system. The brightest segment (*a*) and the fainter and wider inner ring (*b*) along with the very faint components (*c*) and (*d*).

We thank the many JPL and NASA personnel who worked on Voyager and made the successful flybys of Jupiter possible. We also thank Dr J. E. Hansen, L. Moriboto and S. Synnott and the navigation team for their support in data reduction calculations. This paper represents the results of one phase of research carried out at the JPL and NASA contract NAS 7-100.

Note added in proof: We have searched carefully for evidence of a shadow from the rings on the surface of the planet, using Voyager 1 images when lighting conditions were optimal. No indication of a shadow was found, even though our resolution was twice the expected shadow width (~50 km). Pre-discovery reports of ground-based observations of the shadow—at resolutions more than 150 times worse than that of the spacecraft—are probably incorrect.

Directive segregation is the basis of ColE1 plasmid incompatibility

John R. Bedbrook*, Hans Lehrach† & Frederick M. Ausubel

Department of Biology, Biological Laboratories, Harvard University

Incompatibility between ColE1 plasmids in Escherichia coli *can be explained by competition for a limited number of replication sites. These sites ensure directive segregation of plasmids to daughter cells on cell division. The number of sites can be more than one only if a linear segregation mechanism is postulated.*

Plasmid incompatibility is defined as the failure of two plasmid replicons to be stably maintained in the same bacterial cell. Two general types of models have been postulated to explain plasmid incompatibility. One is derived from the replicon hypothesis of Jacob, Brenner and Cuzin[1]. They proposed that each bacterium has a single site at which particular plasmids are replicated. The site acts as a directive segregation mechanism which ensures that each daughter cell receives a copy of the attached plasmid. Incompatibility is due to competition between plasmids belonging to the same compatibility group for this single essential replication site. A second model, proposed by Pritchard and coworkers[2-3], is based on the observation that an Hfr strain cannot harbour a free F factor. According to this model, incompatibility results indirectly from the action of trans-acting cytoplasmic factors (repressors) whose actual physiological function is to regulate plasmid copy number. When two plasmids produce and are sensitive to the same repressor, there is an increased probability that a daughter cell will not receive both plasmids because the combined copy number of the two plasmids is equal to the normal copy number of each plasmid alone.

Plasmid incompatibility among small non-conjugative plasmids has been investigated[4,5], and Warren and Sherratt[6] have recently demonstrated that any two plasmids derived from ColE1[7] replicons are incompatible. They found that smaller ColE1 derivatives displaced larger ones and argued that this was consistent with a replication repressor model for plasmid incompatibility. The conclusion was based on the assumption that smaller plasmids have less affinity for the postulated replication repressor than larger plasmids. There is now evidence for the existence of replication repressors[8]. These experiments indicated that pSC101[9] copy number is controlled by a trans-acting factor.

In the experiments reported here, we have used two families of multicopy plasmids to investigate further the mechanism of plasmid incompatibility. One family is characterised by ColE1 and the other by RSF1030[10]. Our results can be summarised as follows: (1) RSF1030 and its derivatives were compatible with ColE1 and its derivatives; (2) when two ColE1 derivatives were used to simultaneously transform *rec*A$^-$ *E. coli* resultant double transformants existed only temporarily; (3) the hybrid RSF1030-ColE1 replicon and a single ColE1 replicon were stably maintained in the same cell; and (4) multimer forms of pMB9[11] were incompatible with each other. Our results support the view that plasmid incompatibility is the consequence of a directive segregation mechanism for plasmid propagation. The phenomenon of incompatibility is not associated with plasmid copy number control and the results are not consistent with a model postulating that replication repressors are the primary cause of plasmid incompatibility.

Co-transformation of *E. coli* by two plasmids as a system for plasmid incompatibility studies

One way to study plasmid incompatibility is to simultaneously introduce a single copy of each of two phenotypically distinguishable, incompatible plasmids into a single *E. coli* cell. Figure 1 demonstrates that significant numbers of double transformants (arising by simultaneous transformation with two incompatible ColE1 plasmids) could be obtained at DNA concentrations at which double transformants were the result of two independent single-hit events by the two incompatible plasmids. The number of cells obtained that were resistant to a single drug was directly proportional to the concentration of DNA used in the transformation and the saturating DNA concentration of 6×10^{-9} M was the same for each plasmid. We have no simple explanation for the observation that the number of transformants obtained at any particular molar concentration of DNA was greater for RSF1030 than for the ColE1 derivatives pML21[12] and pMB9 and in turn was greater for pMB9 and pML21 than for another ColE1 derivative pSF2124[13].

Formation of double transformants with two compatible plasmids (RSF1030 and pML21 or RSF1030 and pMB9) was also log-linearly related to plasmid DNA concentration. The slope of the line log(number of transformants) versus log(DNA concentration) is ~2, as expected for two independent random events. The number of double transformants also plateaued at 6×10^{-9} M DNA. The formation of pMB9–pML21, pMB9–pSF2124 or pML21–pSF2124 double transformants were not log-linear with DNA concentrations. Nevertheless, significant numbers of double transformants were obtained within the range of plasmid DNA concentrations at which double transformants for compatible plasmids arose by two independent events. We have ruled out the possibility that double transformant colonies are a consequence of mutual crossfeeding of plasmid products from separate pMB9 and pML21 transformants. When pML21-containing cells and pMB9-containing cells were patched together at high concentrations on a plate containing tetracycline (Tc) and kanamycin (Km) no growth of the patch was observed.

Genetic instability and plasmid composition of cells of double transformant colonies

A *rec*A$^-$ strain (HB101) was simultaneously transformed with pMB9 (Tc^r) and pML21 (Km^r) and the cells were plated immediately on Tc+Km media. The colonies that grew on the double selection plates were purified on nonselective medium so

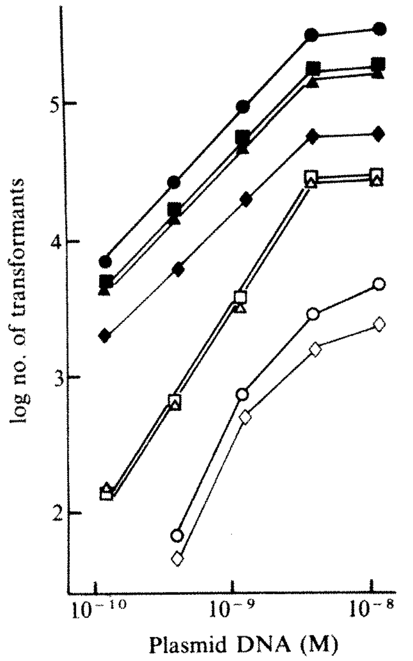

Fig. 1 Frequency of the formation of single and double transformants as a function of plasmid DNA concentration. HB101 ($r_B^- m_B^-$ F^- *pro*$^-$ *gal*$^-$ *arg*$^-$ *rec*A$^-$) (ref. 16) was grown at 37 °C in LB media containing per litre 10 g bacto tryptone (Difco), 5 g yeast extract (Difco) and 5 g CaCl *p*H 7.2. Cells at mid log growth were collected and resuspended in one half growth volume of chilled 30 mM $CaCl_2$, incubated at 4 °C for 20 min, pelleted and resuspended in $\frac{1}{50}$ of the growth volume of 30 mM $CaCl_2$. Approximately 4×10^7 viable $CaCl_2$ treated cells were incubated at 4 °C with mixtures of pMB9, pML21 and RSF1030 plasmid DNAs or pMB9, pML21 and pSF2124 plasmid DNAs at the indicated DNA concentrations for 60 min. The DNA concentration given is the concentration of each plasmid DNA alone. The cell–plasmid DNA mixtures were incubated at 42 °C for 2 min., diluted 10-fold in LB media, and grown for 20 min. at 37 °C. This time was adequate to give the maximum number of transformants. Aliquots of cells at various dilutions were plated on LB media containing 1.5% Difco agar. To select for the presence of RSF1030 and pSF2124, plates contained 30 μg ml^{-1} ampicillin; to select pMB9, plates contained 10 μg ml^{-1} tetracycline; and to select pML21, plates contained 20 μg ml^{-1} kanamycin. RSF1030 (●), pMB9 (■), pML21 (▲), pSF2124 (◆), RSF1030 + pMB9 (□), RSF1030 + pML21 (△), pMB9 + pML21 (○), and pMB9 + pSF2124 (◇). The number of transformants plotted is corrected for a constant viable cell count.

that individual cells from the original colony could be tested for Tc^r, Km^r and Tc^r + Km^r. Each original Tc^{r}Km^r colony contained cells which were either Tc^r or Km^r. No cells were resistant to both Tc and Km. These results indicated that while primary doubly transformed cells must have contained both plasmids, in further generations individual cells propagated only one of the two plasmids.

Figure 2 shows that the proportion of Tc^r cells in a doubly transformed colony that were Tc^r (contained pMB9) varied between 0 and 100% depending on the Tc concentration. (The Km concentration was 20 μg ml^{-1} in all plates and the Tc concentration was 1–10 μg ml^{-1}). We interpret these results as follows: Primary transformants containing both pMB9 and pML21 synthesise products which confer Tc^r and Km^r, respectively. These products are distributed to daughter cells. Some daughter cells propagate pMB9 and others propagate pML21. The cells propagating pMB9 are Tc^r and, for some period of time, are also Km^r, as they received Km^r-conferring products from the primary transformed cell. Similarly, cells propagating pML21 are Km^r and retain a Tc^r phenotype until the Tc^r-conferring products are diluted out. The number of divisions before the critical dilution occurs when daughter cells become Tc^s will depend on the Tc concentration in the medium. Thus the higher the concentration of Tc, the lower the proportion of cells in the double transformant colony that contain pML21. In contrast, at very low Tc concentrations, cells propagating pML21 will have a significant growth advantage over those propagating pMB9 as the latter cells must detoxify the Km in the medium with pML21 products which are continually being diluted at each cell division. Thus, this experiment supports the notion that doubly resistant transformant colonies are a mixture of two cell types, each type propagating one of the two plasmids initially entering the primary transformant.

Table 1 Description of plasmids used

Plasmid	Compatibility group	Description	Relevant phenotype	Source or reference
pMB9	ColE1	pMB1 derivative	Tc^r	11
pML21	ColE1	ColE1 derivative	Km^r	12
pSF2124	ColE1	ColE1 derivative	Ap^r	13
RSF1030	RSF1030	Naturally occurring	Ap^r	10
pJC307	ColE1	Temperature sensitive mutant	will not replicate at 42 °C	15
pHM15	ColE1	pJC307::Tn5::Tn10	Tc^{r}Km^r	H. Meade
pJB28	ColE1	pJC307 + Km^r from pML21	Km^r	This paper
pJB56	RSF1030	RSF1030 + Km^r from pML21	Ap^{r}Km^r	This paper
pJB55	RSF1030 +ColE1	RSF1030-pML21	Ap^{r}Km^r	This paper

Primary double transformant cells replicate both plasmids

The ability of plasmids, temperature-sensitive for replication, to give rise to transformant colonies at the non-permissive temperature for plasmid replication was tested: pJB28, a ColE1 derivative containing the same genes for Km^r as pML21, and pHM15, a ColE1 derivative containing the Tc^r gene (see Table 1), were used to transform the strain HB101. The transformed cells were plated directly at 32 °C and 42 °C over a range of drug concentrations. At drug concentrations adequate to select Tc^r or Km^r, no transformants were obtained at the non-permissive temperature (42 °C), in spite of the fact that the plasmids were entering the cells (as witnessed by the growth of many transformants at 32 °C). Thus, a single copy of a plasmid was not sufficient to allow the growth of a visible colony.

Figure 3 shows that replication of both plasmids must occur in the primary transformed cell. When pJB28 transformants were preincubated at 32 °C before plating at 42 °C, the number of Km^r colonies which formed depended on the length of the preincubation time at 32 °C. The maximum number of colonies was obtained after a preincubation period of 180 min. On retesting, however, less than 0.1% of the cells in colonies forming at 42 °C were Km^r. This experiment showed that a plasmid-containing cell will form a colony on media that selects for a plasmid-coded drug resistance only if plasmid replication is allowed to occur in the cell before plating. Another observation, supporting the view that double transformant colonies arise as a consequence of a period of replication of both plasmids in the primary double transformant, is that the double transformant colony size is inversely related to the length of time that the cell population is grown unselectively before selective plating. This indicates that the number of viable daughters which the plated cell produces depends on how close in the cell lineage it is to the primary transformant.

A site model for plasmid incompatibility

The results described above have led us to the conclusion that when pMB9 and pML21 are used to simultaneously transform *E. coli*, both plasmids replicate in the primary transformed cell.

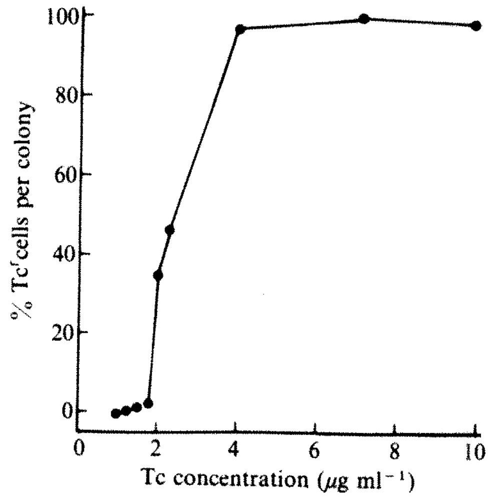

Fig. 2 Plasmid composition of daughter cells of double transformants. pMB9–pML21 plasmid double transformants of HB101 were prepared as described in Fig. 1 legend. Doubly transformed cells were selected on LB agar plates containing Km (20 μg ml^{-1}) and Tc (1–10 μg ml^{-1}). Colonies appearing on double selection plates were streaked onto LB agar plates and grown at 37 °C for 20 h. For each datum point, a minimum of 100 colonies were tested for resistance to Tc and Km.

In subsequent daughter cells only pMB9 or pML21 is able to replicate. The replicon hypothesis of Jacob *et al.*[1] can explain these results. Specifically, we propose that *E. coli* contains a site or sites at which ColE1 plasmids are replicated and that this is the basis of multicopy plasmid incompatibility. Once in occupancy, the resident plasmid at a site is not readily displaced by another ColE1 plasmid in the cytoplasm. Before cell division, the replication site or sites are duplicated and occupied by plasmid molecules that are the direct descendents of the plasmids occupying the parent sites. Any two ColE1 derivatives are incompatible because only a single plasmid molecule has access to each replication site.

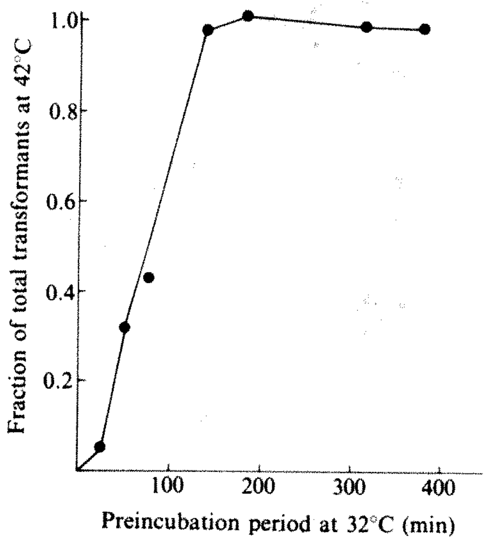

Fig. 3 Growth of pJB28 transformants at 32 °C and 42 °C. pJB28 was constructed by ligation, *in vitro*, of *Eco*RI linearised pJC307 with the *Eco*RI fragment of pML21 containing the genes for Km^r. Purified pJB28 plasmid DNA at a concentration of 5 μg ml^{-1} was used to transform HB101 as described in Fig. 1 legend except that the heat pulse was at 32 °C and the cells were not grown in broth before plating. Aliquots of the transformation mixture were grown on LB agar plates containing 10 μg ml^{-1} Km at 32 °C and, at the indicated times, transferred to 42 °C. Colonies were counted after 24 h of growth at 42 °C. As a control, several plates were incubated at 32 °C only.

In its simplest form, this site model predicts that *E. coli* contains a single site for ColE1 plasmid propagation. The results presented above indicate that both pMB9 and pML21 replicate in primary transformants. To reconcile this result with a single site replication model, it is necessary to propose that some fraction (about 1–5% based on Fig. 1) of a logarithmically growing population of *E. coli* cells transitorily contain two sites for ColE1 propagation. Such cells may have duplicated the single site but not undergone cell division at the time of transformation by plasmid DNA. Double transformants could arise if pMB9 occupies one and pML21 occupies the other site of such cells. Both plasmids could then replicate within this single cell until the point at which cell division occurs and the two sites are segregated. After cell division pMB9 continues to be replicated and propagated in one of the daughter cells and its progeny, and pML21 in the other daughter cell and its progeny. The random segregation of the non-site bound copies of both plasmids and their protein products enables the transitory maintenance of the double transformant phenotype.

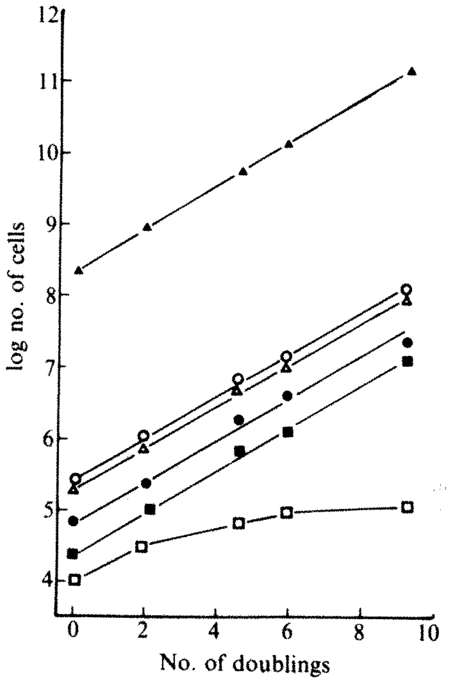

Fig. 4 Kinetics of segregation of pMB9 and pML21 from pMB9–pML21 double transformants. pJB56 was constructed by joining a derivative of RSF1030 containing an *Eco*RI site with the *Eco*RI fragment of pML21 containing the gene for Km^r. Mixtures of pMB9 and pJB56 DNAs or mixtures of pMB9 and pML21 DNAs (all at 20 μg ml^{-1}) were incubated with 10^8 CaCl$_2$-treated HB101 cells. After incubation on ice for 60 min, the cells were heated to 42 °C for 2 min, diluted 10-fold in LB, and incubated at 37 °C for 20 min. Aliquots of transformed cells were plated on broth plates and on plates containing 10 μg ml^{-1} Tc, 20 μg ml^{-1} Km, and 10 μg ml^{-1} Tc + 20 μg ml^{-1} Km. The remaining cells were diluted fivefold in LB and grown for two doublings at which time the plating was repeated. This last procedure was repeated several times to give about 10 generations of growth. Plates were incubated at 37 °C for 30 h and all visible colonies were counted. Total cells (▲), pMB9 (○), pML21 (△), pJB56 (●), pMB9 + pJB56 (■), pMB9 + pML21 (□).

Alternatively, *E. coli* may contain more than one replication site for ColE1 plasmids and double transformants could arise simply by two different plasmids acquiring one of the multiple sites. For a multiple site model to be in keeping with our data it is necessary to assume that the sites are segregated in a linear directive fashion. On cell division each site is duplicated, maintaining the linear arrangement with respect to one another. Half the linear array of sites are segregated to one daughter cell and half are segregated to the other daughter cell.

We present additional results below which support a replication site model as the basis of ColE1 incompatibility.

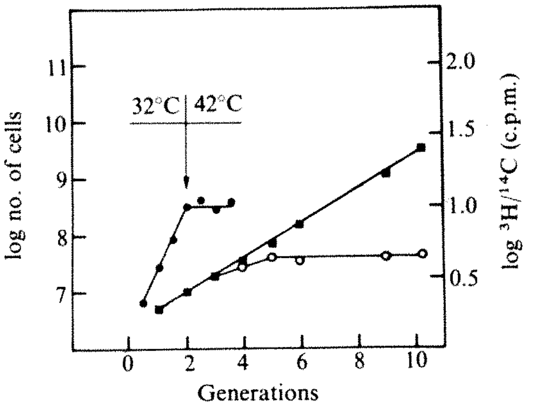

Fig. 5 Kinetics of segregation of pJB28 plasmid. *E. coli* strain FMA119 ($F^- su^- gal^- Sm^R recA^- thyA^- deo^-$) containing the temperature-sensitive replication plasmid pJB28 was grown in LB at 32 °C or 43 °C through ~10 doublings of the total population. Logarithmic growth was maintained throughout by successive dilution of the culture. At times indicated, aliquots of the culture were removed and plated on LB agar containing Km (20 μg ml^{-1}). In a separate experiment, FMA119 cells containing pJB28 were grown in 50 ml of minimal media supplemented with 2 μg ml^{-1} thymine and 20 μg ml^{-1} ^{3}H-thymine. Cells were grown for 2 doublings at 32 °C in the presence of the label then diluted by a factor of 5 in the same media and grown at 43 °C for 2 doublings. At the times indicated 10-ml samples were removed and mixed with equal aliquots of FMA119 cells grown at 32 °C containing pJB28 which had been labelled with ^{14}C-thymine. The cells were pelleted, washed in 10 ml cold 10 mM Tris-HCl, *p*H 8.0, 1 mM EDTA and resuspended in 0.2 ml 20% sucrose containing 10 mM Tris-Hcl *p*H 8.0. the cells were incubated with lysozyme (2 mg ml^{-1}) for 5 min at 4 °C, 0.25 ml 0.25 M EDTA was added, the mixture was incubated at 4 °C with occasional gentle mixing, 0.25 ml of lysis buffer containing 1% Brij 58, 0.4% sodium deoxycholate, 6.25 mM EDTA and 10 mM Tris-HCl *p*H 8.0 was added, and the mixture was incubated at 45 °C for 2.5 min. The lysed cells were centrifuged at 17,500 r.p.m. for 60 min at 4 °C in a Sorvall SS34 rotor in an RC2B centrifuge. The supernatant solution was extracted with equal volumes of phenol and chloroform. After an additional chloroform extraction, the aqueous phase was precipitated with ethanol. The precipitate was washed with 65% ethanol, dried, resuspended in 0.2 ml H_2O and mixed with 1 μg purified pJB28 DNA. The samples were applied to 1% agarose tube gels (1 cm × 12 cm) and electrophoresed at 3 mA per gel for 14 h. Electrophoresis conditions, gel staining and photography were as described by Bedbrook and Bogorad[17]. the fluoroescence corresponding to supercoiled pJB28 DNA was sliced from the gel, soaked in aquafluor for 16 h, and assayed in a liquid scintillation counter. The radioactivity incorporated into pJB28 DNA at 32 °C and 43 °C are superimposed with the results obtained for pJB28 segregation at 32 °C and 43 °C. ●, Ratio of ^{3}H c.p.m. in pJB28 DNA to the standard amount of ^{14}C c.p.m. in pJB28 DNA. ■, Number of cells plating on Km plates after growth at 32 °C. ○, Number of cells plating on Km plates after growth at 42 °C.

The kinetics of segregation of double transformants

Figure 4 illustrates experiments in which the kinetics of the segregation of pMB9-pML21 double transformants were compared with those of pMB9-pJB56 (a Km^r-conferring derivative of RSF1030) double transformants. Double transformants were constructed as described in Fig. 1 legend. The total cell population used in the transformation was then grown logarithmically without selection for about 10 doublings. At various times, samples were plated to assay total cell number and the presence of the two plasmids. The fraction of the total population transformed by pMB9 or pML21 was about 10^{-3} and the fraction transformed by pJB56 was about 2×10^{-4}. The number of pMB9-pML21 double transformants was about 10% that of the single transformants. This number is likely to be an underestimate of the absolute number of primary double transformants as some segregation must occur during the unselective growth period before the first plating. The total cell population grew logarithmically throughout the experiment and no loss by segregation of single pMB9 or pJB56 transformants or double pMB9 + pJB56 transformants was observed after 10 generations. pMB9–pML21 double transformants increased initially, in a non-log-linear fashion, to give ~10 times the number of "doubly transformed" cells. After six doublings of the total cell population, the number of pMB9–pML21 double transformants had plateaued. These data corroborate the experiments described above which showed that pMB9–pML21 double transformants are unstable and can only exist for short periods of time.

Figure 5 shows that the kinetics of segregation of pMB9–pML21 double transformants are similar to the kinetics of distribution of pJB28 to daughter cells following a shift to the nonpermissive temperature for pJB28 replication. At 32 °C, both the growth of Km^r cells and the replication of pJB28 (as shown by ^{3}H-thymidine incorporation in plasmid DNA) are log-linear. After transfer to 42 °C, plasmid DNA synthesis stopped within the temperature shift and the next measurement of plasmid synthesis (20 min). In contrast, the number of Km^r-resistant cells increased in a non-linear fashion during the first four doublings of the total cell population at 42° C, at which point the number of Km^r cells plateaued.

Comparison of Figs 4 and 5 shows that the extent of growth of pJB28-containing cells following a shift to 42 °C is similar to the increase in pMB9–pML21 double transformants immediately following transformation. This relationship suggests that the 10-fold increase in pMB9–pML21 double transformants was due to the distribution to daughter cells of pML21 and pMB9 plasmids which were produced in the primary transformed cell. These kinetic observations are consistent with a site model of plasmid replication because they indicate extremely rapid cessation of replication of one of the two plasmids in the daughter cells of the primary transformant. This leads rapidly to a steady state condition in which there is no net increase in double transformants. Moreover, the 'double transformants' obtained are genetically unstable and cannot be maintained even by selection. These observations are not consistent with a

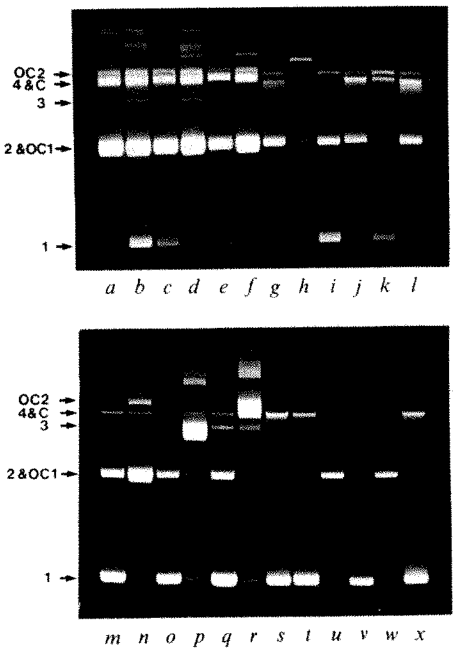

Fig. 6 *E. coli* propagates only one multimer form of pMB9 per cell. *E. coli* strains JC1157 and JC1157 *rec*A ts (ref. 16) were transformed with pMB9 monomer DNA as described in Fig. 4 legend. Transformed cells were plated at 32 °C on LB agar containing 10 μg ml^{-1} Tc. Cells from colonies of JC1157 (pMB9) and JC1157 *rec*A ts(pMB9) grown at 32 °C were plated again at 32 °C and 42 °C. Six colonies from each of the four platings were used to prepare plasmid DNA as described in Fig. 5 legend. Plasmid DNA samples were electrophoresed in 1% agarose gels. Electrophoresis is from top to bottom. pMB9 DNA from various colonies of JC1157 grown at 32 °C (lanes *a–f*), from JC1157 grown at 42 °C (lanes *g–l*), from JC1157 *rec*A ts grown at 32 °C (lanes *m–r*), and JC1157 *rec*A ts grown at 42 °C (lanes *s–x*). pMB9 supercoiled monomers (1), pMB9 supercoiled dimers (2), pMB9 supercoiled trimers (3), pMB9 supercoiled tetramers (4), pMB9 open circular monomers (OC1), pMB9 open circular dimers (OC2), and chromosomal DNA (C).

model which invokes copy number repressors as the basis for plasmid incompatibility because repressor models predict an indefinite log-linear increase in the number of double transformants. With a positive selection for both plasmids one expects to maintain an increasing lineage of cells containing both plasmids[6], even in an extreme case in which two incompatible plasmids have very different affinities for the replication repressor.

Transformation of cells containing resident plasmids

Table 2 lists the transformation frequencies obtained when pMB9 was used to transform HB101 containing various resident plasmids. In this experiment the transformation frequency of HB101 by pMB9 was 10^{-5} per cell. This frequency was reduced by more than three orders of magnitude when HB101 contained pML21 but was unaffected by the residency of pJB56, a compatible plasmid. Residency by pJB55, a hybrid replicon between RSF1030 and pMB9, reduced the transformation frequency by pMB9 to a similar extent as that caused by pML21, but residency by pMB9 did not affect the transformation frequency of pJB55.

These data can be explained by a site model for incompatibility. As discussed above, the exchange of plasmids at the replication site is postulated to be an infrequent event. Thus, the accessibility of the site to an incoming plasmid would be greatly reduced if the site were already occupied by an incompatible resident plasmid. The hybrid replicon pJB55 could reside at both the sites for ColE1 and RSF1030 replication. When in residence, pJB55 would be expected to prevent pMB9 from acquiring the site. On the other hand, the hybrid plasmid should be able to acquire the RSF1030 site when pMB9 is the resident plasmid.

We have found that pMB9–pJB55 double transformants are propagated stably and indefinitely. This result is not consistent with a replication repressor model for plasmid incompatibility as repressor synthesised by the ColE1 portion of the RSF1030–ColE1 hybrid replicon would be expected to induce the segregation of pMB9.

Physical evidence for a directive segregation model

Experiments shown in Fig. 6 provide physical evidence that *rec*A$^-$ *E. coli* is capable of replicating only a single ColE1 plasmid per cell. for this experiment we took advantage of the following: (1) pMB9 plasmid molecules undergo reciprocal recombination in *rec*$^+$ cells to form plasmid multimers at high frequency[14]. In contrast, multimer forms are stably propagated in *rec*A$^-$ *E. coli.* (2) A temperature sensitive (ts) *rec*A$^-$ mutant of *E. coli* forms plasmid multimers when the plasmid-containing strain is grown at 32 °C but not at 42 °C.

In the experiment shown in Fig. 6, the fate of plasmid multimers formed and present in the cells of the ts *rec*A$^-$ strain grown at 32 °C, was followed when the temperature was shifted to 42 °C. As a control, *rec*$^+$ strain, otherwise isogenic with the ts *rec*A$^-$ strain was used. Cultures growing at 32 °C were plated for single colonies at 32 °C and 42 °C and plasmid DNAs derived from single colonies were examined by gel electrophoresis. For the *rec*$^+$ strain (Fig. 6*a–l*), six colonies analysed at 32 °C and 42 °C all contained different multimer forms. Various multimers were also seen in DNA preparations from the ts *rec*A$^-$ colonies plated at 32 °C (Fig. 6*m–r*). When the ts *rec*A$^-$ strain was plated at 42 °C, however, individual colonies contained only one plasmid size class (Fig. 6*s–x*): four contained monomers and two contained dimers. That is, the ts *rec*A$^-$ strain propagated only one of the possible size classes of pMB9 plasmid molecules at 42 °C despite the fact that the cells growing at 32 °C contained various multimer forms.

Table 2 Effect of resident plasmids on transformation frequency

Transforming plasmid	Resident plasmid	Transformation frequency per cell
pMB9	None	10^{-5}
pMB9	pML21	$<10^{-8}$
pMB9	pJB56	10^{-5}
pMB9	pJB55	$<10^{-8}$
pML21–RSF1030 hybrid (pJB55)	pMB9	10^{-6}

Strain HB101 containing the indicated plasmids was grown in LB media containing 20 μg ml^{-1} Km or 10 μg ml^{-1} Tc as appropriate. Approximately 10^9 cells were transformed with 1 μg of the indicated plasmid DNAs as described in Fig. 1 legend. Transformants were grown in LB media containing 10 μg ml^{-1} Tc or 10 μg ml^{-1} Km to select the resident plasmid and then plated on LB solid medium containing 10 μg ml^{-1} Tc and/or 20 μg ml^{-1} Km to select both the resident and the incoming plasmid. The transformation frequency indicated is the number of cells containing both resident and incoming plasmids divided by the total number of cells used in the transformation.

Discussion

We have presented evidence that strongly supports the view that incompatibility between ColE1 plasmids is a direct consequence of competition between plasmids for a single or a limited number of plasmid replication site(s). Our results contrast other studies[6,8] which show that *E. coli* strains are capable of maintaining two ColE1 plasmid replicons over many generations. The results of these studies are best explained if plasmid incompatibility is envisaged to be the consequence of transacting repressors which normally regulate plasmid copy number. A significant difference in the experimental design of these previous studies and the experiments described here is that we have used *rec*A$^-$ strains. We have shown previously that reciprocal recombination occurs between plasmid molecules in *rec*$^+$ (but not in *rec*A$^-$) *E. coli* leading to the formation of plasmid multimers[14]. Recombination occurs only at regions of homology and is reversible. We showed that stable double transformants can be obtained when pMB9 and pML21 are used to simultaneously transform a *rec*$^+$ strain. These doubly transformed strains contain hybrid pMB9–pML21 plasmids[14].

The phenomenon of plasmid–plasmid recombination can be invoked to reconcile our observations with previous studies. Assume that a *rec*$^+$ strain is replicating a pMB9–pML21 hybrid plasmid (formed *in vivo* by recombination) at a ColE1 replication site. Occasionally, intramolecular recombination of the site bound hybrid plasmid will occur and will result in occupation of the site by pMB9 or pML21 instead of the pML21–pMB9 hybrid. From this point on, the site will only replicate pMB9 or pML21 and one of the two plasmids may be segregated away unless it regains access to the replication site by recombination.

Warren and Sherratt[6] found that smaller ColE1 plasmids with high copy numbers usually displaced larger, low copy number plasmids. This observation can also be explained by plasmid–plasmid recombination. Assume that a hybrid ColE1 replicon is comprised of two plasmids, which, as monomers, are present in different copy numbers. Following intramolecular recombination and cell division, daughter cells carrying the 'high copy' replicon at the replication site will contain a high ratio of 'high copy' monomers to hybrids. In comparison, daughter cells which contain the 'low copy' replicon at the replication site, will contain a lower ratio of monomers to hybrids. The higher the ratio of monomers to hybrids, the lower the probability that the replicating monomer at the site will recombine with a hybrid plasmid to restore the double transformant genotype. A similar argument can be made for large versus small plasmids. A small site bound plasmid would have less extensive homology with the hybrid plasmids in the cytoplasm than would a large site-bound plasmid. This decreases the probability that a small site-bound plasmid would recombine with a cytoplasmic hybrid plasmid, increasing the probability that the small plasmid would displace the larger one. That is, recombination may be the basis of incompatibility hierarchies among ColE1 replicons[6]; if so such hierarchies would not be expected to be observed in *rec*A$^-$ strains.

We conclude that plasmid incompatibility is the consequence of ordered, directive segregation of replication sites. For pMB9 and pML21 plasmids attachment to the replication site seems to be irreversible. Certain ColE1 plasmid derivatives appear to segregate from *E. coli* strains spontaneously (Ausubel and Ow, unpublished). Presumably such plasmids have an altered affinity for the replication site, compared with say pMB9, such that the binding with the site is unstable. For these plasmids the affinity for the replication site and copy number control would be important in controlling incompatibility. Take for example a primary double transformant *rec*A$^-$ cell containing a 'stable' attachment plasmid at one site and an 'unstable' attachment plasmid at another site; daughter cells sufficiently distant in the cell lineage from the primary cell to have completely segregated the replication sites may still contain non-site-bound plasmids of both types. If at this point the 'unstable' attachment plasmid was uncoupled from a replication site exchange with the stable attachment plasmid may occur thus switching the plasmid 'genotype' of the cell. Hierarchies of incompatibility could be generated by variable affinities of various plasmids for the replication sites.

We thank D. Helinski for providing pJC307 before its publication and a referee for drawing our attention to the potential importance of attachment bias of plasmids to replication sites. Three new types of viral oncogene of cellular origin specific for haematopoietic cell transformation

M. Roussel, S. Saule, C. Lagrou, C. Rommens, H. Beug*, T. Graf* & D. Stehelin†
INSERM, Oncologie Moléculaire, Institut Pasteur de Lille, 15 rue C. Guérin F 59000 Lille, France

*Institut für Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D6900 Heidelberg, FRG

The RNAs of seven replication-defective leukaemia virus (DLV) strains contain three types of unique sequences, which correlate with the capacity of a given virus strain to transform erythroblasts, macrophage-like cells and myeloblasts, respectively. These sequences, termed erb, mac *and* myb, *have their counterparts in the normal DNA of avian and mammalian species. Our results indicate that DLVs represent recombinants between a common 'vector' related to a chicken endogenous virus and one of three types of cellular gene possibly involved in haematopoietic differentiation.*

ON the basis of their oncogenic properties, avian retroviruses are assigned to either of two major classes. Of many characterised natural field isolates, most (non-defective avian leukaemia viruses, or ALVs) are 'weakly oncogenic' and cause predominantly lymphatic leukaemia after a latency period of months to years following inoculation into susceptible strains of chickens. The ALVs most frequently occur as independent agents containing all the genetic information required for viral replication. In contrast, several avian retroviruses are highly oncogenic, causing disease after a latency period of days to weeks. These include the replication-competent avian sarcoma viruses (ASVs, or Rous sarcoma viruses) which readily induce sarcomas in susceptible birds and transform fibroblasts *in vitro*, and also the replication-defective leukaemia viruses (DLVs) which require helper ALVs for propagation in cultured cells (for review, see ref. 1).

The seven available independent isolates of DLVs have been assigned to three subgroups based on the types of neoplasm they induce and on the differentiation phenotypes of haematopoietic cells they transform *in vitro*[1,2]. (1) The avian erythroblastosis-type viruses (AEV strains R and ES4 are probably identical[3]) induce erythroblastosis *in vivo* and transform erythroblasts *in vitro*. (2) The avian myelocytomatosis-type viruses (MC29, CMII, OK10 and MH2) transform macrophage-like cells *in vitro* and some strains induce myelocytomatosis *in vivo*. (3) The avian myeloblastosis-type viruses (AMV and E26) induce myeloblastosis *in vivo* and transform myeloblasts *in vitro*. AEV can also induce sarcomas and transforms fibroblasts *in vitro*, and MC29-type viruses can induce carcinomas and occasional sarcomas and transform epithelial cells and fibroblasts *in vitro*[1,2]. In this report we have investigated whether the oncogenicity of these viruses could be related to the presence of specific nucleotide sequences in their genome. Such a relationship would imply that part or all of these specific sequences represent new viral oncogenes.

DLVs are related to non-defective avian leukaemia viruses

DLVs were originally isolated from chickens in association with their natural replication-competent helper viruses belonging to the ALV group. Attempts to complement DLVs with helpers unrelated to ALVs have failed[4]. A possible homology between certain genomic sequences of the DLVs and ALV genes[5–7] was

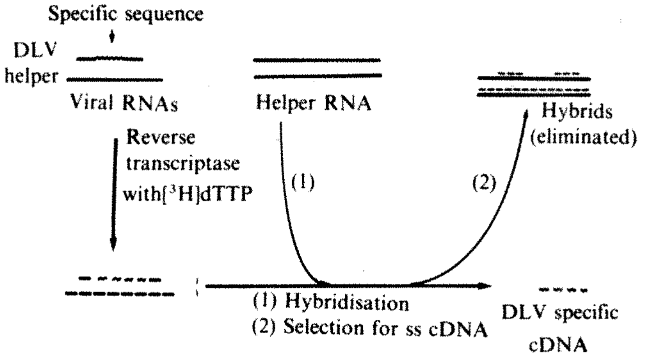

Fig. 1 Scheme for the preparation of DLV-specific cDNAs. Cloned AEV (RAV-2) and MC29 (RAV-2) pseudotypes, obtained by rescuing these viruses with RAV-2 from cloned nonproducer fibroblasts, were propagated in chicken fibroblasts. Viral RNAs were extracted from the pelleted viruses, then transcribed into labelled cDNA using *in vitro* reverse transcription with purified AMV reverse transcriptase, ^{3}H-dTTP and unlabelled dCTP, dGTP, dATP and calf thymus priming. In a negative selection step each cDNA mixture was hybridised to an excess of RNA extracted from RAV-2 grown separately. Single-stranded DLV-specific cDNAs were then isolated after fractionation on hydroxyapatite. AMV-specific cDNA was prepared in a similar way, but using RNA of AMV (helper) pseudotype obtained from the plasma of infected chickens, and a mixture of ALV helper RNAs extracted from RAV-1, RAV-2 and MAV-2 (0) viruses for the selection. Non-hybridisable radioactivity was eliminated from the cDNAs by a positive selection with homologous RNAs[8] (not shown). Specific activities of the ^{3}H-cDNAs were $\sim 50 \times 10^6$ c.p.m. per μg. Details of these experiments will be described elsewhere.

investigated by testing clones of avian cells containing the DLV provirus without its helper. Such cells, usually unable to produce virus[6], still contain several RNA transcripts of the DLV provirus. We tested whole RNA of such nonproducer cells, using molecular hybridisation with labelled probes representing a homogeneous transcript of an ALV, td Pr-B (cDNArep), or of the *src* gene of ASVs (cDNAsarc)[8]. Table 1 indicates that all the DLV genomes tested contain ALV-related nucleotide sequences in different amounts (28–77%), but lack the *src* gene of ASV[9,10]. However, the detected homology to ALV cannot account for the entire genetic content of the DLVs, which all contain 6,000–8,000 nucleotides in their 28–34S genome[11,12]. Thus, these viruses may contain sets of nucleotide sequences unrelated to ALVs.

DLV-specific sequences

We looked for specific sequences by analysing the prototype strain of each of the three DLV subgroups, namely AEV, MC29 and AMV. Clone viral strains were obtained for AEV and MC29 by superinfection of nonproducer cells with the plaque-purified helper virus RAV-2. The rescued viruses were then tested for their oncogenic potential *in vitro* (using the bone marrow transformation assay[2]) and propagated in chicken erythroblasts (for AEV) or chicken fibroblasts (for MC29). AMV was obtained in high yields from the plasma of infected chickens.

The preparation of specific cDNAs of these viruses (Fig. 1) was similar to the selection of cDNA specific for the *src* gene of ASVs[8]. cDNAs of AEV, MC29 and AMV were selected so that they could still hybridise to their RNAs of origin, but not to the RNA of the helper viruses used to grow the viral stocks or any of the other ALVs tested. These specific cDNAs were denoted cDNAaev for AEV, cDNAmc29 for MC29 (ref. 13) and cDNAamv for AMV.

The distribution of viral nucleotide sequences related to these specific cDNAs was explored by hybridising them at plateau C_rt values to several viral RNAs. The results (Table 2) allow several conclusions to be drawn. First, the cDNAs tested are specific for the DLVs used for their preparation. Second, they represent distinct sets of sequences, unrelated to each other by cross-hybridisation experiments, and third, cDNAmc29 shows extensive homology to RNA of CMII, OK10 and MH2, as does cDNAamv to E26 RNA. As will be described elsewhere, the three cDNAs exhibited exactly the same specificity when tested with cellular RNAs extracted from nonproducer cells, further demonstrating that the probes indeed detect sequences specific for the three types of DLV.

Table 1 DLV genomes in nonproducer cells are related to ALVs

DLV strain	Type of nonproducer cell	Annealing (% S_1 resistance) with cDNArep	cDNAsarc
AEV	chicken fibroblast	28	<3
MC29	quail fibroblast	45	<3
CMII	quail fibroblast	41	<3
OK10	quail fibroblast	77	<3
MH2	quail fibroblast	32	<3
AMV	chicken myeloblast	50	<3
E26	chicken myeloblast	36	<3

Total RNA was extracted from the different avian nonproducer cells and hybridised in stringent conditions (25-μl aliquot containing 1–10 mg ml^{-1} RNA, 0.6 M NaCl, 68 °C) with cDNAs (1,000 c.p.m. per point = 0.02 ng) to plateau C_rt values (defined as 10× the $C_rt_{1/2}$). cDNArep and cDNAsarc were prepared as described earlier[3], but using calf thymus-primed polymerase reactions[14]. Hybrids were assayed by S_1 nuclease. No correction for the expression of endogenous RAV-O or cellular sarc was made as they gave values below 3% in each case.

To investigate the origin of the DLV-specific sequences, DNA extracted from normal avian cells was tested for its ability

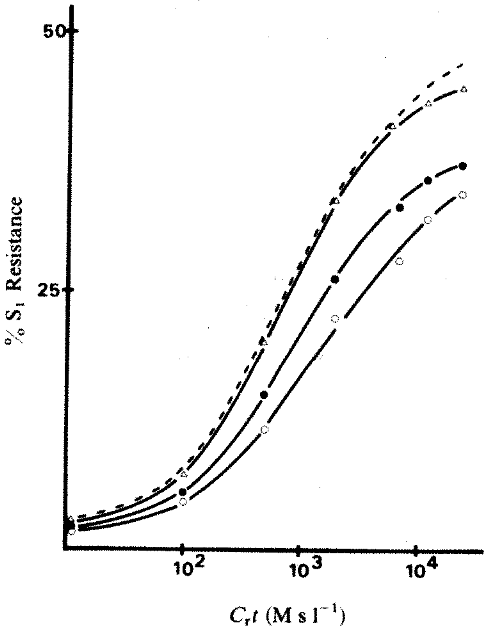

Fig. 2 DLV-specific sequences have their couterparts in normal chicken DNA. Aliquots of 11-day chicken embryo DNA (200 μg per point, sheared to 4–6S) were hybridised with the different specific cDNAs (1,000 c.p.m. per point = 0.02 ng) in stringent conditions (0.6 M NaCl, 68 °C) at increasing C_0t values. Hybrids formed were tested for their resistance to S_1 endonuclease. ●—●, cDNAaev; △—△, cDNAmc29, ○—○, cDNAamv; ----cDNAsarc. Similar results were obtained with normal quail embryo DNA (not shown).

Table 2 DLVs contain unique nucleotide sequences

RNA derived from	Annealing (% S_1 resistance) with cDNAaev	cDNAmc29	cDNAamv
AEV	100	<3	<3
MC29	<3	100	<3
CMII	<3	96	<3
OK10	<3	91	<3
MH2	<3	66	<3
AMV	<3	<3	100
E26	<3	<3	68
ALV helpers (control)	<3	<3	<3

Viral 50–70S RNAs were extracted and hybridised to plateau C_rt values ($>10\ \mathrm{M\,s\,l^{-1}}$) in stringent conditions (0.6 M NaCl, 68 °C) with the specific cDNAs (1,000 c.p.m. per point = 0.02 ng). The hybrids formed were tested for S_1 nuclease resistance. Results obtained were standardised to the values of the homologous reaction. Maximum hybridisation of cDNAaev with AEV RNA was 95%; that of cDNAmc29 with MC29 RNA 90% and that of cDNAamv with AMV RNA 95%. The DLVs tested were cloned pseudotypes with RAV-1 or RAV-2 helper ALV, with the exception of AMV and E26, which were not cloned. The ALV helper RNAs tested as controls were obtained from RAV-1, RAV-2, RAV-49, RAV-50, MAV-2 (0). The numbers boxed indicate the important homologies.

to hybridise with cDNAaev, cDNAmc29 and cDNAamv. Figure 2 shows that all three types of sequences have their counterparts in normal cellular chicken DNA and, as judged from the $C_0t_{1/2}$ values, that they are present in the non-repetitive DNA at one or two copies each per haploid genome. The low plateau values observed in Fig. 2 are due to the competition of DNA reassociation with the DNA–cDNA hybridisation reaction; transcription analyses (see below) show that most or all of the specific sequences are present in normal chicken DNA. Results obtained with molecular hybridisation in liquid phase in stringent conditions show that the bulk of the non-repetitive chicken DNA sequences have been lost relatively rapidly during evolution: labelled chicken unique sequence DNA barely anneals (Fig. 3) to the DNA of species from another genus. For example, quail and chicken, which probably evolved from a common ancestor some 20–40 Myr ago, have DNAs that share less than 25% homology when cross-hybridised (Fig. 3). Similarly, ALV-related 'virogene' sequences have recently been shown to be absent in some species of the Galliformes[14]. In contrast, cellular sequences related to cDNAaev, cDNAmc29 and cDNAamv have been highly conserved throughout the phylogeny of the higher vertebrates. As also shown in Fig. 3, their 'evolutionary half lives' are comparable to those of known stable genes such as globin or ovalbumin. The latter values resemble thoses obtained earlier for the transforming gene *src* of ASVs[15–17] and agree with the results recently described for MC29 by Sheiness *et al.*[18].

As normal cells contained nucleotide sequences related to highly transforming viruses, we studied the rate of transcription of such sequences. Total RNA extracted from normal chicken (or quail) fibroblasts was hybridised to the different specific cDNAs. Figure 4 shows that these sequences are all transcribed at a low level (a few copies per cell), as previously found for the expression of "cellular sarc" (refs 16, 19). Cellular sequences related to cDNAaev are transcribed at two or three copies per cell; cellular sequences related to cDNAmc29 are reproducibly expressed at a higher level (5–10 copies per cell), as Sheiness *et al.*[18] found. In contrast, cellular sequences related to cDNAamv are transcribed at lower levels in fibroblasts (one copy per cell). As can be seen in Fig. 4, all these cellular sequences reach plateau hybridisation values close to 100%, and must therefore be essentially fully represented in normal cellular nucleic acids.

Three new oncogenes

Our results show that all seven defective leukaemia viruses studied contain part or all of one out of three different sets of specific nucleotide sequences complementary to cDNAaev, cDNAmc29 or cDNAamv, which have their counterpart in normal cells of higher vertebrates. None of these sequences is related to the transforming gene *src* of ASVs. Although it is not understood how recombinants between ALV sequences and cellularly derived sequences can acquire oncogenic capacity, several indications favour the hypothesis that three specific transforming genes, termed *erb*, *mac* and *myb*, are detected by cDNAaev, cDNAmc29 and cDNAamv, respectively. (1) There is a strict correlation between the presence of *erb*, *mac* or *myb* sequences in a given virus and its selective capacity to generate transformed erythroblasts, macrophage-like cells or myeloblasts[1,2,20]. (2) The properties of these sequences and their origin are reminiscent of results obtained earlier for the transforming gene *src* of ASVs[15]: size, cellular origin and phylogenetic stability[16,17]. (3) As indicated by heteroduplex mapping studies with MC29 (ref. 21), these sequences do not appear as bits of sequences randomly distributed throughout the viral RNA, but rather as continuous stretches located inside the viral genome. (4) Temperature-sensitive mutants have recently been isolated from AEV, indicating that a virus-coded protein must be synthesised to maintain the undifferentiated state of transformed erythroblasts[22]. (5) All DLVs tested contain the 5′ region of the ALV genome (partial *gag* gene[12]). In the strains studied so far (MC29 and MH2) this region was located adjacent to the DLV-specific sequence[21,23]. In addition, cells nonproductively transformed by AEV, MC29, CMII and MH2 express novel polyproteins of molecular weight 75,000 (ref. 3), 110,000 (refs 6, 7), 90,000 (ref. 7) and 100,000 (ref. 4), respec-

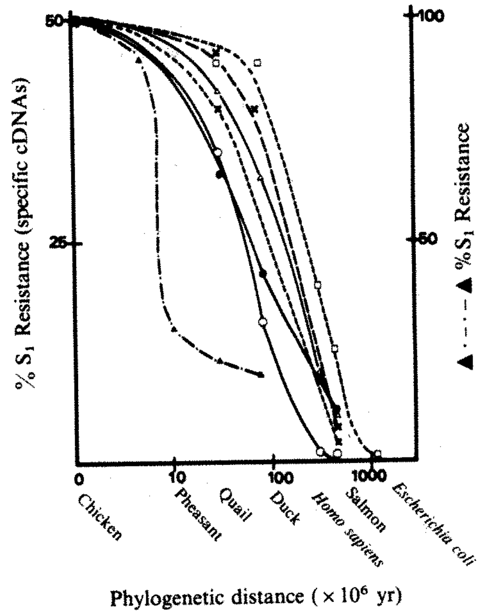

Fig. 3 Stability of cellular DLV-related specific sequences during evolution. Aliquots of DNA extracted from different species having diverged increasingly long ago with speciation were hybridised in the specific conditions described in Fig. 2. The values obtained were standardised arbitrarily, for comparison purposes, to 50% for the chicken, which was also taken as the origin of the scale indicating phylogenetic distance. ●—●, cDNAaev; △—△, cDNAmc29; ○—○, cDNAamv; □- - -□, cDNAsarc. Also shown (▲ · — · —▲) are results obtained with ^{3}H-labelled chicken unique sequence DNA[14](1,000 c.p.m. per point = 20 ng) in similar conditions (standardised to 100% for homologous reassociation) and with cDNAs representing genes known to be conserved throughout the evolution of vertebrates; ×— —×, cDNAlgo (ref. 16) for globin; ×- - - - -×, cDNAova (ref. 16) for ovalbumin.

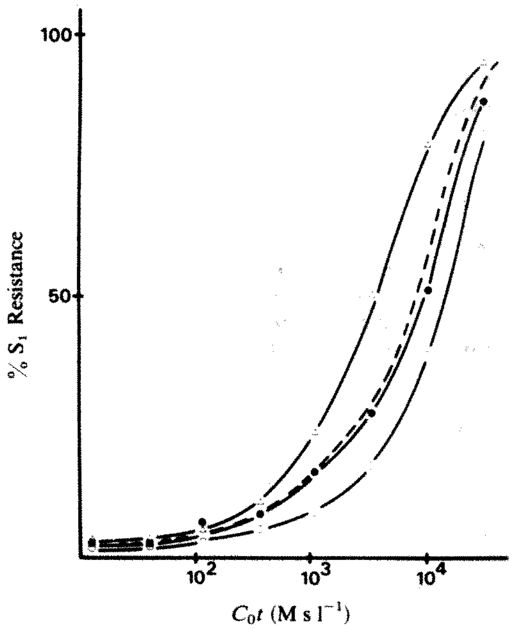

Fig. 4 Transcription of the cellular DLV-related specific sequences in normal fibroblasts. Total RNA was extracted from normal chicken embryo fibroblasts and hybridised at increasing C_rt values (varying RNA concentration up to 10 mg ml^{-1}) in stringent conditions (0.6 M NaCl, 68 °C), to the specific cDNAs (1,000 c.p.m. per point = 0.02 ng). Hybrids were scored for their S_1 endonuclease resistance. Symbols are as in Fig. 2.

tively, with the structure: partial *gag-x* or *y*, where *x* or *y* represent polypeptide moieties which are antigenically unrelated to known ALV proteins, and presumably correspond to part or all of the specific *erb* or *mac* nucleotide sequences. That these polyproteins could be involved in the transformation process is indicated by the finding that the type of tryptic peptide pattern exhibited by the non-*gag* portion of the polyprotein of a given DLV closely correlates with the transformation specificity of the virus (M. J. Hayman, personal communication, and ref. 24). In their general structure and ability to code for *gag*-related polyproteins, avian DLVs resemble replication-defective mammalian retroviruses capable of inducing leukaemias or sarcomas with a short period of latency, such as the Abelson[25] murine virus and feline sarcoma virus[26,27].

Avian DLVs behave like recombinants between an ALV-related vector virus of low oncogenicity and unknown origin[14] and an evolutionarily stable set of nucleotide sequences of cellular origin. In this regard they also closely resemble ASVs (for review, see ref. 11). The mechanism of such a recombination remains to be elucidated, but could be related to the jumping polymerase hypothesis proposed recently by Coffin[28]. How frequently such a recombination occurs is not known, although about 30 DLV-like and 1–3 ASV-like independent isolates have been reported[2]. However, a transduction of cellular sequences would not necessarily lead to such severe effects as the generation of a highly oncogenic virus and may therefore be much more frequent than anticipated. Indeed, we have recently found in an ASV stock a new virus of unknown oncogenicity containing apparently unknown cellular genetic material (N. Pluquet and D.S., unpublished).

That only a partial homology was observed between the specific sequences of MC29 and MH2 as well as between the specific sequences of AMV and E26 (Table 2) can be explained in three ways—these viruses acquired cellular genes which already differed in their sequences; they acquired the same gene and the observed differences reflect a divergence introduced by passage of the virus; a second recombination event occurred in MH2 and E26. The finding that there are only one or two copies per haploid genome of these genes present in cellular DNA is consistent with the second possibility. The observation that there is a somewhat lower degree of homology of cDNAamv to cellular DNA than that of the other types of specific cDNA tested (Fig. 2) might reflect the long passage history of AMV and would also agree with the second of the above interpretations. But hybridisation experiments between cDNAmc29 and MH2 RNA carried out in non-stringent conditions do not show the significant increase of annealing which the second interpretation would predict (M.R., S.S. and D.S., unpublished) and thus leave that question unanswered.

The role of DLVs in leukaemic transformation could be explained by a generalisation of the 'differentiation block' hypothesis[22,24]: the oncogenes of DLVs are homologous to normal cellular genes ('cellular *erb*, *mac* or *myb*') coding for lineage-specific haematopoietic differentiation proteins; the transforming proteins act by competitively inhibiting the corresponding cellular proteins[2,17], thus leading to a block of differentiation and subsequent leukaemogenesis. This hypothesis would predict that RNA sequences corresponding to the cellular *erb*, *mac* and *myb* genes are preferentially expressed in normal erythroblasts, macrophages and myeloblasts, respectively. Spontaneous leukaemogenesis may then simply result from a malfunction of such genes. Indeed, several different genes may be able to induce the same type of leukaemia. In this respect, it would be interesting to know whether there are viruses causing the same type of leukaemia but containing different cell-related oncogenes. Such viruses would also be useful for elucidating why the DLVs also induce sarcomas or carcinomas, an additional specificity for non-haematopoietic tissues difficult to explain by the differentiation block theory.

We thank Drs B. Royer Pokora and K. Bister for providing cells, N. Oker-Blom and L. Gazzolo for OK10 and MH2 viruses, M. Bellard and A. Therwarth for cDNAs of globin and ovalbumin, M. B. Raes for technical assistance, N. Devassine for typing, Drs C. Sherr, R. Marusyk and M. Hayman for helpful corrections and discussions. AMV polymerase, PR-C ASV and chicken plasma were provided through the NCI (Office of Resources and Logistics). This work was supported by INSERM (ASR-1-018 and CRL 77.5.054.2), CNRS (AI, ERA 225), DGRST (77.7.1879) and the Pasteur Institute of Lille.

T4 DNA topoisomerase: a new ATP-dependent enzyme essential for initiation of T4 bacteriophage DNA replication

Leroy F. Liu, Chung-Cheng Liu & Bruce M. Alberts

Department of Biochemistry and Biophysics, University of California, San Francisco, California 94143

A novel ATP-dependent DNA topoisomerase which makes reversible double-strand breaks in the DNA double helix has been purified to near homogeneity from T4 bacteriophage-infected Escherichia coli *cells. Genetic data suggest that this activity is essential for initiating T4 DNA replication forks* in vivo.

THE process of DNA replication fork movement can be successfully duplicated *in vitro* and has been shown to require several different types of purified protein[1,2]. In contrast, the process of replication intiation, whereby new replication forks are established at specific chromosome origins, has not yet been reconstituted with purified components. As a result, our knowledge of the enzymology of fork initiation is rather limited (for review see ref. 3).

Genetic studies of T4 bacteriophage development have indicated that the products of T4 genes *39*, *52* and *60* probably interact with each other to form a complex, and that this complex is essential for normal T4 DNA replication[4]. When any one of these three T4 proteins is defective, replication still begins at about the same time as in the wild type, but the rate of the initial phase of DNA synthesis is reduced[5]. This slow rate of DNA synthesis results from a low incidence of replicative forks, rather than from any reduction of the fork movement rate[6]. The products of genes *39*, *52* and *60* are thus believed to be involved in the initiation of T4 DNA replication[6].

Here, we report the discovery, properties and purification of a new ATP-dependent DNA topoisomerase. DNA topoisomerase is the name suggested for a class of enzymes that catalyse the concerted breaking and rejoining of DNA backbone bonds, as these activities are invariably detected by their ability to promote the interconversion between different topological isomers of DNA (for review, see ref. 7). The T4-induced DNA topoisomerase characterised here seems to be composed of proteins coded for by T4 genes *39*, *52* and *60*. The properties of this enzyme suggest ways in which it can act to initiate replication forks at T4 chromosome origins. A similar complex of T4 proteins has been independently isolated by Stetler, King and Huang[8], using an *in vitro* complementation assay to monitor gene *39* protein activity.

A new ATP-dependent DNA topoisomerase activity induced by T4 bacteriophage infection

Infection of *Escherichia coli* with T4 bacteriophage results in a marked increase in the ability of a cell lysate to relax covalently closed superhelical DNAs, a reaction which requires at least one transient cleavage of a DNA backbone bond[9]. This conversion of DNA circles from a negatively supercoiled form to a less supercoiled form may be sensitively detected by agarose gel electrophoresis, as shown in Fig. 1 for circular duplex PM2 DNA which has been incubated with various dilutions of an extract. Supercoil-relaxing activity is detected in this crude lysate only after extensive dilution away from the endonucleases which are also present; these nucleases convert the initial DNA substrate (form I DNA) to nicked DNA circles (form II DNA) and unit-length linear DNA molecules (form III DNA). For this reason, a group of DNA bands characteristic of partially relaxed, covalently closed DNA circles (which have an electrophoretic mobility between that of form I and form II DNAs) could be detected only after a 540-fold extract dilution. Surprisingly, no DNA supercoil relaxation was detected when the rATP in the reaction mixture was omitted. This activity was not blocked by antibody to *E. coli* ω protein or affected by the *E. coli* DNA gyrase inhibitor novobiocin (data not shown). The possibility of DNA relaxation by an excess of DNA ligase in the presence of an endonuclease was ruled out, as the same level of supercoil-relaxing activity was found in extracts of cells infected with a T4 DNA ligase (gene *30*) amber mutant (see Table 1). We therefore concluded that the activity detected in Fig. 1 originates from a previously unrecognised DNA topoisomerase. By analogy with other DNA topoisomerases, we assume that this enzyme catalyses both the breakage and the rejoining of DNA backbone bonds; moreover, it must do so in a concerted way, such that the putative intermediate in which a DNA backbone bond is broken exists only transiently. This requirement is necessitated by our failure to detect a population of nicked DNA circles as intermediates in reactions with the purified enzyme (see below).

T4 mutants of genes 39, 52 and 60 eliminate topoisomerase activity

A large number of T4 mutants were screened for the ability to affect or abolish the ATP-dependent DNA topoisomerase activity seen in Fig. 1. For this purpose, sonically disrupted cell extracts were prepared from a variety of T4 mutant-infected cells. The mutants screened for activity are listed in Table 1; of these only *am*N116 (gene 39^-), *am*H17 (gene 52^-) and *am*HL626 (gene 60^-) showed no detectable DNA topoisomerase activity in extracts. As expected, the activity was missing when these amber mutant phages were used to infect a non-suppressing (su^-) *E. coli* host (*E. coli* B); activity was present when the same mutants were used to infect an amber-suppressor strain (*E. coli* CR63). Furthermore, when any two of these three amber mutants were used to co-infect the non-suppressing *E. coli* host (*E. coli* B), the topoisomerase activity was largely recovered (see Table 1). Thus, the genetic complementation observed between mutants in these three genes *in vivo* is matched by activity complementation for the

0028–0836/79/410456—06$01.00

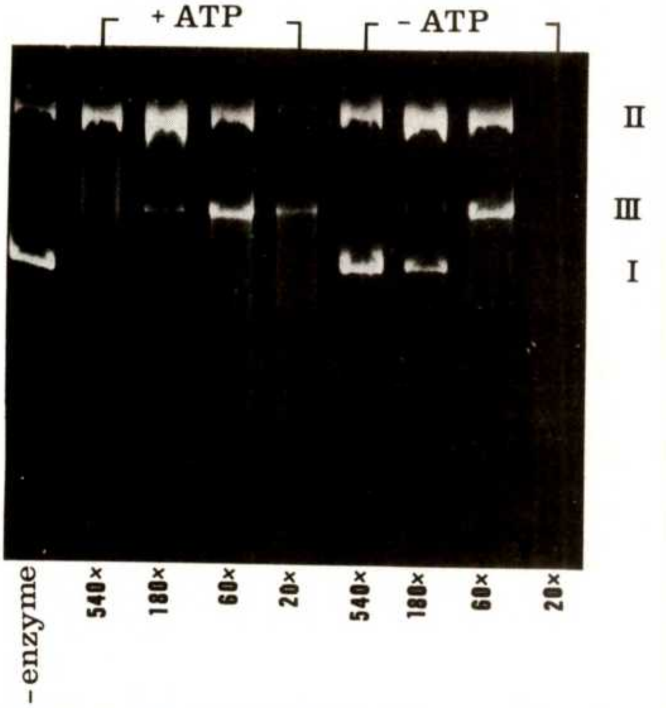

Fig. 1 An ATP-dependent DNA topoisomerase activity can be detected in extensively diluted crude extracts of T4 bacteriophage-infected *E. coli*. The Roman numerals on the right-hand margin indicate the positions after agarose gel electrophoresis of form I (covalently closed, negatively supercoiled duplex DNA circle), form II (nicked DNA circle) and form III (unit-length linear) PM2 DNA molecules. A completely relaxed closed circular DNA would co-migrate with form II DNA on this gel. The bands migrating between form II and form III DNAs in the second lane from the left (adjacent to the no enzyme control) are the covalently closed DNA circles which have a reduced superhelical density due to topoisomerase action. Note that cleavages by endogeneous nucleases produce form II and form III DNAs at high extract concentrations preventing the detection of the topoisomerase activity. Reaction mixtures (20 μl each) contained 50 mM Tris-HCl, *p*H 7.8, 40 mM KCl, 25 mM $MgCl_2$, 0.5 mM dithiothreitol, 0.5 mM Na_3EDTA, 30 μg ml^{-1} human serum albumin, 25 μg ml^{-1} covalently closed circular PM2 DNA and 0.5mM ATP (where indicated). To this mixture, 1 μl of extract diluted to various extents was added to start the reaction; the numbers below each gel lane represent the final dilution of the original extract in the 20-μl reaction. After 30 min at 30 °C, each reaction was stopped by adding 5 μl of 50% glycerol, 5% SDS and 1 mg ml^{-1} bromphenol blue and loaded on a 0.7% agarose gel. The gel was electrophoresed at room temperature in a buffer consisting of 90 mM Tris-borate (*p*H 8.3) and 5 mM $MgCl_2$ for about 15 h at 2.5 V cm^{-1}. To visualise the DNA, the gel was stained with 1 μg ml^{-1} ethidium bromide, visualised on a short-wave UV transilluminator and photographed with Polaroid film type 55. The source of infected cells for these experiments was *E. coli* strain D110 (thy^-, $polA^-$, $endI^-$), which had been infected for 30 min at 37 °C with a MOI of 10 of T4 bacteriophage [*reg*A-*am*N55(*42*$^-$)-*am*H39(*30*$^-$)] in M9 minimal medium supplemented with 0.3% casein hydrolysate, 1 μg ml^{-1} thiamine and 10 μg ml^{-1} thymidine. The infected cells (5×10^8 cells ml^{-1}) were chilled, washed and concentrated 800-fold by centrifugation. After Brij lysis[29], the lysate was centrifuged at high speed (60 min at 35,000*g*), and the supernatant was used as the extract.

topoisomerase in extracts. Note, however, that the identification of the gene 60 product as being involved here is made less clear by complications arising from *E. coli* B–*E. coli* K host-range differences (see refs 4, 5).

Because infection of *E. coli* B with T4 amber mutants in genes *39*, *52* or *60* causes a major delay in DNA synthesis, they have been designated as 'DNA-delay' (DD) mutants[10]. DNA-delay amber mutants infecting su^- *E. coli* eventually produce a substantial burst of progeny phage, although reduced relative to wild-type infection. This suggests that growth of the DNA-delay mutants on a su^- *E. coli* depends on a host function which is only partially effective[4]. Using drug inhibition studies, McCarthy recently demonstrated that one compensating host factor is *E. coli* DNA gyrase, as, unlike wild-type T4, the growth of T4 gene *39*, *52* and *60* mutants is very sensitive to the DNA gyrase inhibitors coumermycin and novobiocin[11,12]. Using autoradiography to measure the replication fork rates during gene *52* mutant infections, McCarthy *et al.*[6] have further suggested that the DNA-delay mutants are defective only in the initiation of T4 DNA replication, as the fork rates observed are normal.

Table 1 T4 mutants in genes *39*, *52* and *60* eliminate the T4 DNA topoisomerase activity

T4 mutant	Relative T4 DNA topoisomerase activity Su^- *E. coli*	Su^+ *E. coli*
Uninfected	<5	<5
*am*H39 (*30*$^-$)	(100)	(100)
*an*N116 (*39*$^-$)	<5	25
*am*H17 (*52*$^-$)	<5	25
*am*HL626 (*60*$^-$)	<5	100
*am*N116 (*39*$^-$)+*am*H17 (*52*$^-$) co-infection	20	NT
*am*H17 (*52*$^-$)+*am*HL626 (*60*$^-$) co-infection	15	NT
*am*HL626 (*60*$^-$)+*am*N116 (*39*$^-$) co-infection	30	NT

Both *E. coli* CR63 (su^+) and *E. coli* B (su^-) were grown at 37 °C in 20 ml of H broth to a cell density of 5×10^8 cells ml^{-1}; each culture was then infected at a MOI of 10, for each of the indicated T4 bacteriophages. At 12 min after infection, the cells were chilled, pelleted and resuspended in 320 μl of 50 mM Tris-HCl, *p*H 7.8, 50 mM KCl, 10 mM β-mercaptoethanol and 1 mM Na_3EDTA. Each batch of cells was broken by sonication and centrifuged for 15 min at 8,000*g* in an Eppendorf model 3200 centrifuge. Serial dilutions of each supernatant were then assayed as described in Fig. 1 legend, except that 0.2 mg ml^{-1} naladixic acid was present in each assay. The activity in each extract was estimated by comparing the relaxation activity with that in serial dilutions of the T4-*am*H39 (gene *30*$^-$, DNA ligase) infected *E. coli* B extract, whose activity was taken as 100. Other mutants tested, with activities comparable to wild type were *am*N134-*am*BL292-*am*E219 (*33*$^-$, *55*$^-$, *61*$^-$), SP62-*am*N55-*am*H39 (*reg*A$^-$, *42*$^-$, *30*$^-$), *am*HL628 (*59*$^-$), *am*N011 (*47*$^-$), *am*N130 (*46*$^-$)-*am*E727 (*49*$^-$), and the large non-essential deletions: Δ(far P13), Δ(63–32) and $\Delta(39\text{–}56)_{12}$-$alc^-$-ΔSaΔ9(ac–denB)-nd28(denA). NT, not tested.

Purified T4 DNA topoisomerase has multiple components

Starting from 100 g of T4-infected *E. coli* cells, 0.8 mg of highly purified T4 DNA topoisomerase was obtained following the multi-step procedure given in Fig. 2 legend. The total purification, estimated from specific activity measurement, was 350-fold, with a yield of 5%. With a unit of activity defined as the amount of enzyme necessary to induce half-relaxation of 0.3 μg of pBR322 DNA in 30 min at 30 °C in our standard reaction mixture (see Fig. 1 legend), the final DNA–cellulose-purified T4 DNA topoisomerase had a specific activity of 10^6 units per mg. As revealed by the Coomassie-stained SDS-polyacrylamide gel shown in Fig. 2, this fraction contains two major protein bands (molecular weights 63,000 and 52,000), which comprise about 70% of the total stained protein in the gel. Based on previous molecular weight estimates[13], these two bands are almost certainly the products of T4 genes *39* (MW assigned at 64,000) and *52* (MW assigned at 51,000), respectively. Two other protein bands with MWs of 23,000 and 16,000 are also present on our gels. Of these two species, only the 16,000-MW protein actually co-purifies with the topoisomerase activity (data not shown). In view of the data presented in Table 1, and the genetic evidence that the gene products of *39*, *52* and *60* interact with each other *in vivo*, it is tempting to identify the 16,000-MW protein as the T4 gene 60 product.

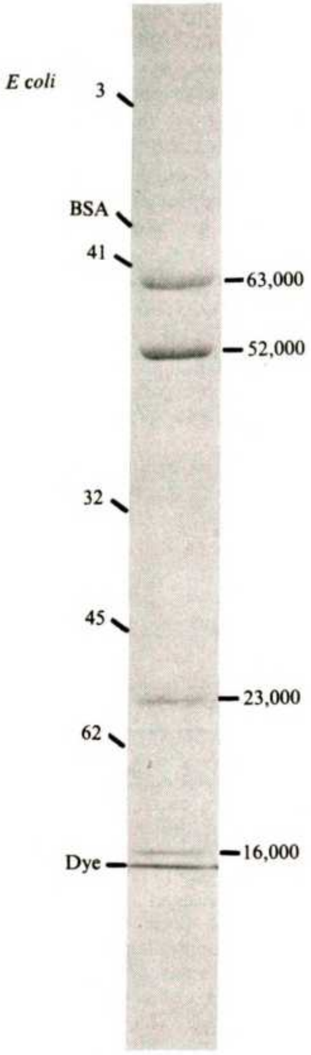

Fig. 2 SDS-polyacrylamide gel analysis of highly purified T4 DNA topoisomerase. A total of 9 μg of purified T4 DNA topoisomerase was denatured in SDS and electrophoresed on a 10% polyacrylamide slab gel[30]; the resulting protein bands were then stained with Coomassie blue as described elsewhere[31]. The approximate polypeptide MWs observed are indicated on the right hand margin, and the migration positions for other purified T4 replication proteins[29,32] used as markers (listed by T4 gene numbers), and for the *E. coli ω* protein[7], are indicated on the left hand margin. To purify the enzyme, frozen T4 (*reg*A-*am*N55-*am*H39) infected *E. coli* D110 cells (100 g) were thawed and resuspended in 150 ml of buffer containing 40 mM Tris HCl, *p*H 7.8, 2 mM Na_3EDTA, 25% sucrose and 95 mg of egg-white lysozyme (Worthington). After 60 min at 0 °C, the cells were lysed by adding 150 ml of 1% (w/v) Brij 58, 40 mM Tris-HCl and 20 mM β-mercaptoethanol and stirring at 0 °C for another 60 min. After centrifugation at 30,000*g* for 1 h, the 330 ml of supernatant was loaded on to a DEAE-cellulose (Worthington DE-52) column (2.5 cm × 24 cm) equilibrated with buffer A (40 mM Tris HCl, *p*H 7.8, 10 mM β-mercaptoethanol, 1 mM Na_3EDTA and 10% (w/v) glycerol). The flow-through fractions were pooled and precipitated by gradual addition of 10% (w/v) polymin P solution (*p*H 7.9) to a final concentration of 0.3%. The precipitate was collected by centrifugation (23,000*g* for 15 min), and the topoisomerase activity was then solubilised by extraction with 100 ml of 0.2 M NaCl (in buffer A). The topoisomerase was precipitated by ammonium sulphate (50 g per 100 ml), collected by centrifugation and redissolved in 30 ml of buffer A. After dialysis overnight against 2 l of buffer A, the topoisomerase was loaded on to a second DE-52 column (2.5 cm × 8 cm) equilibrated with buffer A. The flow through from this column was loaded directly on to a hydroxyapatite column (2.5 cm × 8 cm) equilibrated with solution B (10% glycerol, 10 mM β-mercaptoethanol) containing 20 mM potassium phosphate (*p*H 7.2). After washing the column with solution B containing 0.3 M potassium phosphate, the topoisomerase activity was eluted with solution B containing 0.5 M potassium phosphate. Pooled fractions with activity were dialysed into buffer A containing 50 mM KCl and loaded at 4 ml h^{-1} on to a DNA–cellulose column (1.2 cm × 3 cm containing 1 mg per packed ml of single-stranded calf thymus DNA). This column was eluted successively with buffer A containing 50 mM, 100 mM, 200 mM and 300 mM KCl. The topoisomerase appeared in the 200 mM KCl eluate. The peak activity was pooled and dialysed against a buffer consisting of 30 mM potassium phosphate (*p*H 7.2), 50% (w/v) glycerol, 10 mM mercaptoethanol and 0.5 mM Na_3EDTA, for storage at −20 °C, at which it seems to be quite stable.

The purified T4 DNA topoisomerase can be shown to act catalytically: one enzyme molecule (assumed to have a MW of 131,000) is capable of relaxing to completion at least seven molecules of pBR322 DNA in a 30-min incubation. The topoisomerase activity is completely resistant to novobiocin (up to 60 μg ml^{-1}), but is weakly sensitive to high concentrations of nalidixic acid. This inhibitory effect of nalidixic acid was further studied by using oxolinic acid, a more potent analogue of nalidixic acid; the T4 DNA topoisomerase activity was halved by oxolinic acid at about 250 μg ml^{-1}. As this level of oxolinic acid is about an order of magnitude higher than the concentrations needed for the inhibition of *E. coli* DNA gyrase[14,15], it is likely that the observed inhibition is nonspecific. A similar 'nonspecific' inhibition has been previously observed for another DNA topoisomerase, *E. coli ω* protein, at comparably high oxolinic acid concentrations (500 μg ml^{-1}, ref. 15). When tested with a variety of different circular DNA molecules, the topoisomerase activity shows no obvious DNA preference. The purified enzyme exhibits no DNA gyrase activity with either fully relaxed pBR322 DNA or PM2 DNA in our assay conditions (that is, it is unable to introduce supercoils into these DNA molecules).

Both in the crude extract and in the first DEAE-cellulose breakthrough, the topoisomerase activity is associated with a 30S complex, as judged by sucrose gradient sedimentation (data not shown). This complex can be destroyed, without affecting the ATP-dependent relaxation activity, either by pancreatic RNase A treatment or by salt-extracting the enzyme from a precipitate formed with the synthetic polycation polymin P, as described in Fig. 2 legend. The significance of this apparent RNA association in crude fractions is not known. However, our purified enzyme contains less than 1% nucleic acid, and it sediments more slowly than 5S.

The topoisomerase can catalyse the ATP-dependent relaxation of positive DNA twists

Unlike the *E. coli ω* protein (which can only remove negative turns), T4 DNA topoisomerase catalyses the relaxation of both negatively and positively superhelical DNAs. To assay for the relaxation of positively supercoiled DNA, a fully relaxed PM2 DNA substrate was prepared, and ethidium bromide was added to make this relaxed DNA act as if positively supercoiled. The relaxation of the positive DNA twists present in these conditions can be detected by the increased mobility of the covalently closed PM2 DNA, seen when this DNA is subjected to electrophoresis in the absence of ethidium bromide (see Fig. 3*a*). With our highly purified T4 DNA topoisomerase, we have also demonstrated that: (1) the relaxation of both negative and positive twists is ATP dependent; (2) both reactions are gradual, indicating that the enzyme does not relax the DNA by a one-hit mechanism and that it dissociates from each DNA molecule before relaxing it completely, (3) the enzyme acts catalytically in both cases, in that one T4 DNA topoisomerase molecule can relax many PM2 DNA molecules in a 30-min reaction (data not shown).

ATP hydrolysis is required for catalytic relaxation

The relaxation of superhelical DNAs of both senses is a thermodynamically favourable process. Correspondingly, none of the relaxation reactions catalysed by the other known DNA topoisomerases requires an exogenous source of energy[7]. In contrast, we have shown (Fig. 1) that the T4-induced DNA topoisomerase requires ATP as a cofactor. The requirement for ATP cannot be replaced by other ribo- or deoxyribonucleoside

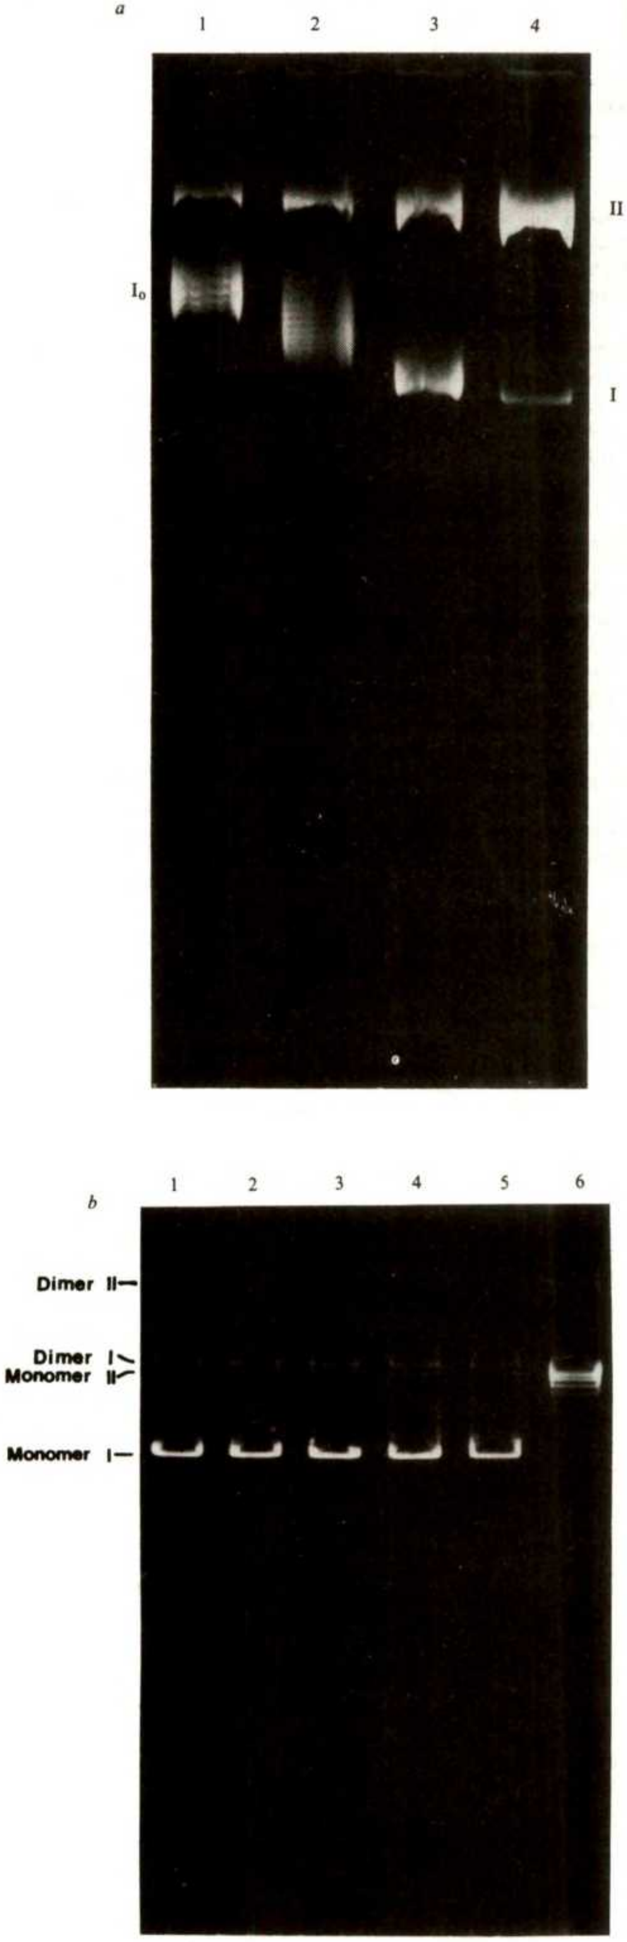

Fig. 3 *a*, The ATP-dependent relaxation of positively superhelical PM2 DNA catalysed by the T4 DNA topoisomerase. Reactions were carried out as described for Fig. 1, except that fully relaxed, covalently closed PM2 DNA (form I_0) was the substrate and ethidium bromide was present at 2 $\mu g\ ml^{-1}$ to induce positive superhelical turns[33]. As the source of the topoisomerase, the breakthrough of the initial DE-52 chromatography step (described in Fig. 2 legend) was used. This partially purified topoisomerase was diluted into the reaction mixture as follows: lane 1, no enzyme; lane 2, 2,000-fold; lane 3, 500-fold; lane 4, 100-fold. Electrophoresis was carried out as described for Fig. 1, but at 4 °C. The removal of ethidium bromide during electrophoresis causes the unreacted substrate DNA to return to a relaxed conformation, but a small amount of negative superhelicity is induced by the low temperature used for electrophoresis. As a result, at 4 °C, the substrate DNA (denoted as form I_0) migrates faster than nicked circular DNA (form II), but more slowly than the highly negatively supercoiled form I DNA. In contrast, the DNA relaxed in the presence of ethidium bromide gains a great deal of negative superhelicity on removal of this dye; thus, the final product of the topoisomerase reaction is the rapidly migrating form I DNA. Note that, with increasing enzyme, increasing numbers of negative supercoils are induced by the topoisomerase in all the covalently closed DNA circles which survive the incubation; this change in superhelicity is only obtained when ATP is present (data not shown). In addition, the topoisomerase still contains an endonuclease contaminant at this stage, which causes the amount of form II DNA to increase as more enzyme is added. *b*, When inducing DNA relaxation, the topoisomerase acts catalytically and requires ATP hydrolysis. Reaction mixtures (20 μl each) contained 50 mM Tris-HCl, *p*H 7.8, 60 mM KCl, 10 mM $MgCl_2$, 0.5 mM dithiothreitol, 0.5 mM Na_3EDTA, 30 $\mu g\ ml^{-1}$ human serum albumin, 20 $\mu g\ ml^{-1}$ form I pBR322 DNA (negatively supercoiled) and 0.2 $\mu g\ ml^{-1}$ of the most highly purified fraction of T4 DNA topoisomerase. Incubations were carried out for 30 min at 30 °C, and the products were analysed as described for Fig. 1. Lane 1 is the no enzyme control; lanes 2–6 represent reactions carried out with 70 μM rATP present, plus different amounts of the non-hydrolysable ATP analogue, ATP-γS, as follows: lane 2, 500 μM; lane 3, 200 μM; lane 4, 50 μM; lane 5, 10 μM; lane 6, no ATP-γS. As nearly complete inhibition of the topoisomerase activity occurs with 10 μM ATP-γS in the presence of 70 μM ATP (lane 5), it is clear that the K_i for ATP-γS is much lower than the K_m for ATP.

triphosphates. This surprising energy requirement has prompted us to investigate the ATP dependence further.

The fact that actual ATP hydrolysis (rather than merely the presence of ATP) is required comes from two lines of evidence. First, the compound rATP-γS [riboadenosine 5′-*O*-(3-thiotriphosphate)] inhibits the topoisomerase reaction strongly when added to our normal reaction mix, as shown in Fig. 3*b*. rATP-γS is an analogue of rATP which is poorly hydrolysed by enzymes which cleave the β–γ phosphodiester linkage of ATP. It acts as an inhibitor of many ATPases, including the activities of the T4 gene *41* and *44/62* proteins (unpublished observation of this laboratory). Second, as shown in Table 2, a DNA-dependent ATPase activity can be detected in the most purified fraction of T4 DNA topoisomerase, for which the hydrolysis products are ADP and inorganic phosphate. With certain assumptions (see Table 2 legend), we can calculate that the number of ATP molecules hydrolysed is roughly equal to the number of superhelical DNA turns relaxed by the topoisomerase.

It is important to note that although rATP-γS is a potent inhibitor of the T4 DNA topoisomerase-catalysed relaxation reaction, it can, nonetheless, stimulate the relaxation reaction in the absence of ATP when the enzyme is present at substrate levels (C.-C.L., unpublished results). This situation is analogou to the effect of a non-hydrolysable analogue of A App(NH)p, on *E. coli* DNA gyrase[16]. For gyrase, the bind ATP seems to induce a conformational change in the which leads to a single cycle of DNA supercoiling; the of ATP is then required to return the enzyme to conformation[16]. The situation for the T4 DNA to probably similar, except that one cycle of D

Table 2 DNA-dependent ATPase activity of the T4 DNA topoisomerase

	ATP hydrolysed (nmol ml^{-1})		
	5 min	10 min	15 min
−DNA	<0.2	< 0.2	0.2
+35 μg ml^{-1} ss fd DNA	0.9	1.9	2.5
+20 μg ml^{-1} pBR322 DNA	2.0	4.0	5.0
+50 μg ml^{-1} T4 ds DNA	3.7	8.3	10.5

The reaction mixtures (20 μl each) were as described in Fig. 1 legend, except that 100 μM [γ-^{32}P]ATP was present. The most purified T4 DNA topoisomerase (0.5 μg) was added to each reaction mixture. After incubation at 30 °C for the times indicated, aliquots (50 μl) of reaction mixtures were withdrawn and added to 0.5 ml of 0.1 M HCl. Hydrolysis was measured as inorganic ^{32}P (as phosphate) separated from unhydrolysed [γ-^{32}P]ATP by charcoal adsorption[27]. The different DNAs present in each reaction mixture are indicated. That the products of hydrolysis are ADP and inorganic phosphate was determined in a separate experiment in which ^{3}H-ATP was used as substrate and the products were analysed by chromatography on PEI-cellulose[28]. From the ATP hydrolysis observed during a 30-min incubation at 30 °C using 0.5 μg of enzyme and 100 μM ATP, we calculate that about 1 pmol of ATP would be hydrolysed by 2.5 ng of enzyme (assuming that the dose response is linear for ATPase activity). In the same conditions, 2.5 ng of enzyme will relax about half of the superhelical turns in 0.1 pmol (as DNA molecules) of pBR322 DNA. As there are about 30 superhelical turns in each pBR322 DNA molecule in our reaction conditions, we estimate that one or two superhelical DNA turns are relaxed for every ATP molecule hydrolysed.

rather than DNA supercoiling, is observed on ATP binding. However, we cannot rule out the possibility that the stimulation is due to a very slow hydrolysis of ATP-γS by the topoisomerase.

Similarities between the T4 DNA topoisomerase and *E. coli* DNA gyrase

At least two kinds of DNA topoisomerase are found in bacteria, as exemplified by the *E. coli* ω protein (*Eco* DNA topoisomerase I) and the *E. coli* DNA gyrase (*Eco* DNA topoisomerase II). *E. coli* ω protein catalyses the energetically favourable partial relaxation of negatively superhelical DNA with no added energy cofactor[17]. In contrast, DNA gyrase[36] catalyses the reverse reaction, introducing negative superhelicity into DNA in a reaction requiring ATP hydrolysis[16,18].

The T4 topoisomerase and the *E. coli* gyrase are multiple-subunit proteins which have both nicking–closing and DNA-dependent ATPase activities. In both cases, these two activities are apparently tightly linked, inasmuch as each cycle of nicking and closing needs to be accompanied by hydrolysis of one (or two) ATP molecules[16,18]. Finally, for both enzymes addition of SDS and protease seems to trap nicked DNA–enzyme intermediates, in which both DNA strands have been broken to produce a unit-length linear DNA molecule from a double-stranded DNA circle (refs 14, 15 and L.F.L., unpublished results). Nevertheless, there is at least one important difference: only the *E. coli* gyrase is able to harness its ATP hydrolysis energy to do useful work (induce DNA supercoiling); so far in our experiments the T4 DNA topoisomerase seems to be wasting this energy, as the reaction catalysed is already thermodynamically favourable without ATP hydrolysis.

might T4 DNA topoisomerase function ork initiation?

ery of T4 bacteriophage has largely been
sing seven highly purified T4 proteins
ication *in vivo*, DNA synthesis has

ates[19]. However, this synthesis
nt reaction which is initiated by
end of a pre-existing DNA nick[19].
initiation, by formation of an *in* *vivo*-like 'replication bubble' on a double-stranded T4 DNA molecule, has not been achieved in this (or any other) purified *in vitro* system. The previously described genetic evidence implying that the T4 gene *52*, *39* and *60* products are specifically involved in T4 replication fork initiation, coupled with the present identification of these proteins as a topoisomerase, suggests that this enzyme may be the missing factor.

The tight coupling between the ATP hydrolysis and relaxation activities of T4 DNA topoisomerase is unique among all known DNA topoisomerases. Although it is possible that the ATP hydrolysis functions directly in the nicking–closing reaction (for example, by being used to provide energy for ligation of the putative broken DNA chain intermediates), it seems much more likely that the ATP hydrolysis energy is normally coupled to another, as yet unidentified, energy-utilising reaction.

We have no direct evidence as to how ATP energy is used by the topoisomerase at the replication origin. However, we will present a speculative model which is suggested by the above-mentioned similarities between the T4 DNA topoisomerase and DNA gyrase. In this view, the T4 DNA topoisomerase serves as a DNA gyrase-like enzyme which acts specifically at the T4 replication origin. Such an enzyme might function to initiate new T4 replication forks in a manner analogous to that schematically outlined in Fig. 4. Here, the T4 DNA topoisomerase would recognise two specific DNA sequences spanning the origin[20] of T4 DNA replication. By anchoring these two DNA sequences on the same enzyme molecule and thereby restricting the rotation of the DNA strands relative to the enzyme, the topoisomerase could create a closed topological domain. This would allow its hypothetical ATP-driven gyration to induce a local negative supercoiling which destabilises the double helix at the replication origin. As indicated, the melting of this origin would presumably require the gene *32* helix-destabilising protein. Participation of the T4 gene *41* and/or gene *44*/*62* replication proteins, destabilising the helix by ATP-driven walking

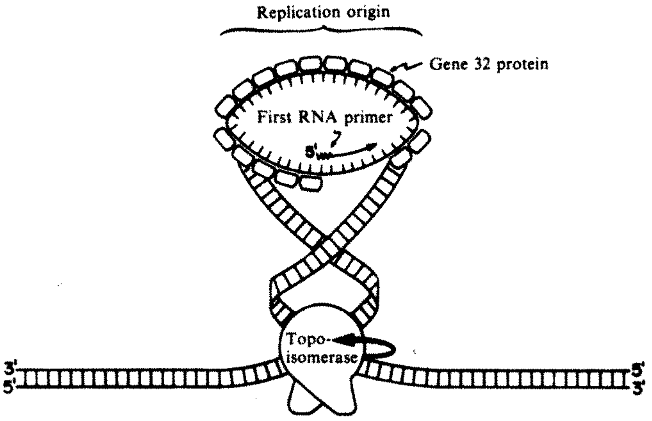

Fig. 4 Two possible models for T4 DNA topoisomerase action at the T4 replication origin. These two models assume (without proof) that the rate-limiting step in generating new replication forks is the opening of the DNA helix at the origin (see text). *a*, Topoisomerase gyration. In this hypothetical scheme, the topoisomerase acts as a site-specific DNA gyrase and uses its ATP hydrolysis and nicking–closing activities to seperate the strands of the DNA helix at the T4 replication origin. The replication origin must form a closed loop, as an isolated domain is required in the otherwise linear T4 DNA molecule to allow supercoiling. This loop could be formed either by the binding of the topoisomerase alone (as indicated here) or by a separate set of proteins or membrane sites. The T4 gene 39 and 52 proteins have been reported to interact with the cell membrane, as well as with DNA[34], and so some membrane attachment might also be used to constrain the DNA origin in this way. (It is interesting that limited topological domains have been detected in the condensed T4 chromosome[35].) In any case, the topoisomerase is suggested to recognise a set of specific DNA sequences which designate a T4 chromosome origin, and to show a DNA gyrase-like activity there (induction of negative twists which destabilise the helix) which is not detected with the non-origin DNA sequences present in our standard topoisomerase assay.

along DNA single-strands[21,22], is also possible. Note that, in this view, the ATP-dependent relaxation of non-origin-containing DNA molecules observed *in vitro* reflects an uncoupled version of a site-specific DNA gyration reaction catalysed by the topoisomerase *in vivo*.

The site-specific gyration model in Fig. 4 postulates that the initial opening of the DNA helix is followed by an RNA-primed DNA chain start, which actually begins DNA synthesis. This first RNA primer could either be synthesised by the same enzymes that prime the Okazaki pieces made on the lagging strand of the T4 replication fork, or be made by a separate mechanism[3,23]. It has been shown recently that the T4 gene *61* protein, in conjunction with the T4 gene *41* protein, can synthesise pentaribonucleotides, and that this synthesis has an absolute requirement for a single-stranded DNA template (ref. 19 and C.-C.L., unpublished results). When additional replication proteins are present, these short ribonucleotides will prime lagging strand DNA synthesis in the T4 *in vitro* system[19]. These two T4 proteins may therefore also have a crucial role in replication fork initiation.

Despite our limited knowledge concerning the mechanism of initiation of DNA replication forks, some similarities can be seen between different systems. As is the case for many other genomes (bacteriophage λ, *E. coli* and eukaryotic chromosomes), replication forks in T4 seem to be able to start out bi-directionally from an initial replication bubble[24]. We therefore expect that a detailed study of the T4 DNA topoisomerase and its interaction with the other T4 replication proteins can provide a model system in which some general properties of fork initiation mechanisms can be elucidated.

Genetic data suggest that genes *O* and *P* of bacteriophage λ may act in a manner analogous to T4 DNA topoisomerase. As for T4 genes *39*, *52* and *60*, the λ *O* and *P* products interact with each other, and when their levels are decreased, the initiation of λ DNA replication is altered[25]. Experiments comparing various lambdoid phages have shown the gene *O* product is highly phage specific, presumably because it recognises origin DNA sequences[26]. Similarly, unlike most T4 genes, gene *39* function cannot be complemented by bacteriophage T2 (W. M. Huang, personal communication); this suggests that gene *39* may have a role in T4 replication which is analogous to the role of gene *O* in λ replication.

Further study of the T4 DNA topoisomerase should also provide valuable knowledge concerning the functions and mechanisms of the important class of enzymes known as DNA topoisomerases. In this respect, we have observed that, at much higher enzyme concentrations (about equal weights of DNA and T4 DNA topoisomerase), a novel ATP-independent DNA topoisomerisation reaction can be detected, in which topologically knotted, double-stranded superhelical DNA molecules are created. Most strikingly, these knots can subsequently be removed by catalytic amounts of the topoisomerase, in an efficient ATP-dependent reaction. As will be described in detail elsewhere, such data reveal that the T4 DNA topoisomerase is working by making transient double-stranded DNA breaks which are rapidly and efficiently resealed in its 'closing' reaction.

While performing an analysis of the NRL HEAO 1 observations of the Virgo cluster and 3C273, we detected X-ray emission from a region between these two objects. The most satisfactory explanation is the presence of two weak X-ray sources, for which we have obtained error boxes. One source is likely to be the peculiar galaxy IC3576, suggested by Margon *et al.*[1] as the source 2U1231+07 = 4U1232+07 (ref. 2). The error box resulting from combining our observations with the 4U data strengthen the X-ray identification with this extremely interesting galaxy. There are numerous possibilities for the other X-ray source, and here we discuss one, the interacting pair of galaxies NGC4410a and NGC4410b (NGC4410a/b).

The field of view of the X-ray detectors is 4° × 1°. The data we used were obtained from the superimposition of parallel scans within ±0.75° of the arc defined by α = 12 h 50.5 min, δ = 16.2° to α = 12 h 17.5 min, $\delta = -1.6°$. The relationship of the 4° × 1° field of view to the scan, and the sky position of several objects is shown in Fig. 1. The average number of counts per 0.5° bin are plotted in Fig. 2. The data have been fitted to a diffuse source model for the Virgo cluster and two point sources for the region between 348 and 352 deg. The 3C273 data were not included in these fits. The least squares fit centres the Virgo cluster at scan angle = 5.9° and the two point sources at scan angles 9.3° and 10.5°, as shown in Fig. 2. The region between 9 and 13 deg is fitted equally well by a diffuse source of core radius 176 arc min, but it is unlikely that a diffuse source so large would be in this region. This region is ≳7° from the Virgo Cluster centre or M87, and, hence, is unlikely to be an extended region of hot gas within the Virgo Cluster. Also, there are no rich clusters or superclusters in this direction, and therefore we believe two point sources to be a more likely interpretation of the data.

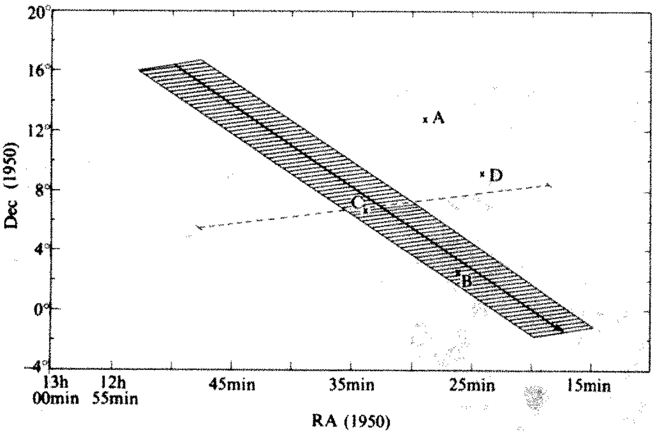

Fig. 1 The ±0.75° wide shaded region shows the portion of the sky covered by the centre of the field of the X-ray collimator over several scans. The arrow shows the direction of the scans for reference with Fig. 2. The dashed line (±4°) delineates the 4° direction of the X-ray collimator (see text). The positions of A, B, C and D are for M87, 3C273, IC3576 and NGC4410a/b, respectively.

The HEAO and Uhuru error boxes are shown in Fig. 3. The corners of the parallelogram lying in both boxes are given by: α = 12 h 35 min 30 s, δ = 6°50′; α = 12 h 31 min 10 s, δ = 7° 19′; α = 12 h 35 min 07 s, δ = 6°38′; α = 12 h 30 min 36 s, δ = 7°10′; and the centroid of the error box is at α = 12 h 33 min 06 s, δ = 6°59.2′. The coordinates of IC3576 are α = 12 h 34 min 5.4 s and δ = 6°53′47″. The area of the parallelogram is 0.25 deg^2. We conclude that the identification suggested by Margon *et al.*[1] is correct. IC3576 is listed as a dwarf galaxy by van den Berg[4], but this is doubtful (see Margon *et al.*[1]). It has been studied in detail at optical and radio[1] wavelengths, and we summarise these results as follows: (1) its magnitude is 15.2 (ref. 5). The galaxy has no well-defined spiral structure and has several blue condensations which might be OB associations; (2) radio observations of the galaxy show a very unusual ratio of neutral hydrogen to optical luminosity, the ratio being almost 10 times greater than that for a normal galaxy and almost twice that for a dwarf galaxy. Its distance is about 20 Mpc[1], and therefore its X-ray luminosity (1–10 keV) is 10^{42} erg s^{-1}. This is about 500 times stronger than that for our own galaxy. IC3576 is clearly worth further investigation.

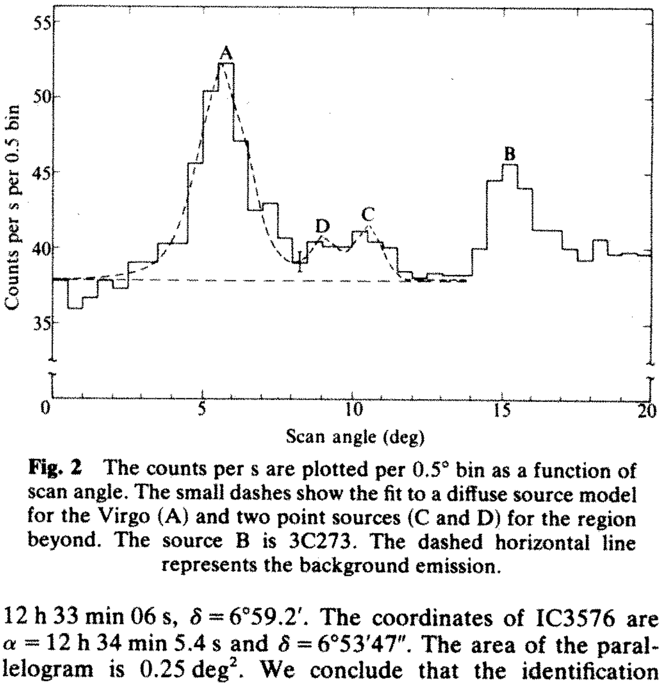

Fig. 2 The counts per s are plotted per 0.5° bin as a function of scan angle. The small dashes show the fit to a diffuse source model for the Virgo (A) and two point sources (C and D) for the region beyond. The source B is 3C273. The dashed horizontal line represents the background emission.

The centroid for the other X-ray object is α = 12 h 34 min 57.6 s, δ = 8°11′24″. The corners of the 90% confidence error box are: α = 12 h 46 min 38.4 s, δ = 7°18′36″; α = 12 h 45 min 12 s, δ = 6°32′24″; α = 12 h 24 min 36 s, δ = 9°49′12″; α = 12 h 23 min 9.6 s, δ = 9°2′24″.

We found no QSOs (in the list by Burbidge *et al.*[6]) in the error box. There is one 4C object, 4C09.41 (ref. 7), just outside the error box, and the interacting pair of galaxies NGC4410a/b within the error box. Condon and Dressel[8] have suggested that a

0028–0836/79/410462—02$01.00

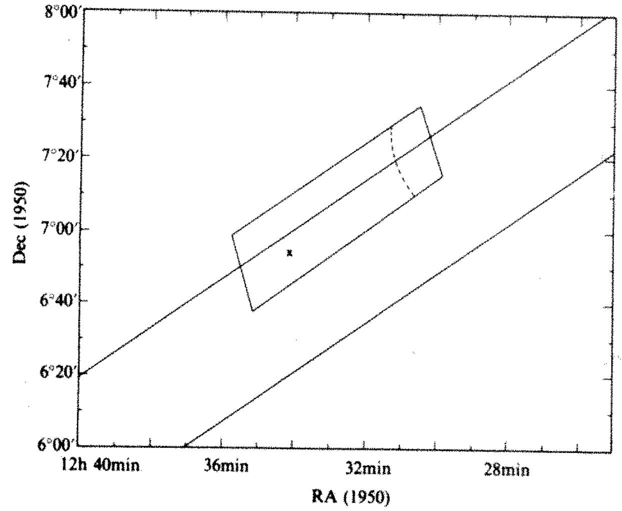

Fig. 3 The error box for 4U1232 + 07 is shown and superimposed on it is a portion of our error box (the two parallel lines). The dashed line, combined with the left hand portion (east) of the 4U error box is the allowed region for the source determined by Margon *et al.*[1]. × represents the position of IC3576 on the sky.

quiescent galactic nucleus might be triggered into radioactivity by a close encounter between two galaxies, and Griffiths *et al.*[9] have extended this idea to the X-ray range by suggesting that interacting pairs are likely to be X-ray sources. Schanberg[10] has shown that the pair NGC4410a/b is indeed interacting, so that, for example, tidal distortion is evident in the outer regions of NGC4410a/b. If the system is an X-ray source, its luminosity is about 5×10^{43} erg s^{-1}.

S.P.B. and M.P.U. thank staff of the NRL for hospitality and support during the data-reduction phase of this work. This research was supported, in part, by NASA contracts to Northwestern University and NRL.
